THE ANNUAL MEETING of the Society for American Archaeology provides a forum for the dissemination of knowledge and discussion. The views expressed at the sessions are solely those of the speakers and the society does not endorse, organizers, not the society.

SYMPOSIUM ABSTRACTS

[1] Forum · PUBLISHING ARCHAEOLOGY IN THE 21ST CENTURY
(SPONSORED BY THE PRESIDENT)
The dissemination of archaeological knowledge forms a core part of the Society for American Archaeology’s mission. The publishing environment is changing very rapidly. This forum explores some of the opportunities and challenges that the SAA, its publication program, and members face: digital publishing, the future of print, open access, data accessibility, financial sustainability, peer review, “gray literature,” and equity among journals, authors, and readers.

[2] General Session · INTERACTION NETWORKS IN THE AMERICAN SOUTHWEST

Dress—the full array of objects, coverings, clothing, pelts, regalia, footwear, pectorals, headdresses, ear ornaments, belts, bracelets and anklets, body paint and hairstyles, as worn, held or otherwise displayed on the human body—is the most supple vehicle for expressing status and identity. Such items of dress are widely noted, excavated, and abundantly documented in images and archaeological corpora. Yet, in the Maya case, very little research has been done about them as separate things or as ensembles. How do such objects work in unison, in what contexts, and with which kinds of people or beings? In her landmark 1950 study of Classic Maya sculpture, Tatiana Proskouriakoff employed some such features to evaluate, primarily, how dress might be employed for dating. Today, the meaning and motivation behind dress and the thematic preoccupations of certain dynasties are accessible as never before. Using this rich body of hieroglyphic, iconographic, and archaeological evidence from the Classic Maya, this symposium aims to craft a comprehensive synthesis of dress in ancient Maya civilization. The papers presented in the session will consider the technical, social, and symbolic aspects of bodily adornment, providing the first systematic study of such classes of objects in more than sixty years.

[4] General Session · LATER PREHISTORY IN AFRICA

[5] General Session · MEDITERRANEAN BRONZE AGE

[6] General Session · SOUTH AMERICA

[7] General Session · NATIVE AMERICAN LAND USE IN THE AMERICAN SOUTHWEST

[8] Symposium · ADVANCES IN THE INVESTIGATION OF PRE-COLUMBIAN GUERRERO AND OAXACA, MEXICO
Recent excavations and surveys in the Mexican states of Guerrero and Oaxaca demonstrate the great potential that the area offers for archaeological research. The objective of this session is to present, from an integrative point of view, the most recent discoveries and interpretations of archaeological investigations in both states. This perspective relies, mainly, on two concerns. First, the modern political boundaries of Guerrero and Oaxaca do not correspond with Pre-Columbian social or political boundaries. In other words, this frontier should be discarded as determinant for knowledge of their ancient inhabitants. Second, investigations in both states are quite disproportionate. Although more archaeological research has been conducted in Oaxaca, archaeological investigations in Guerrero are increasingly common, and they are generating remarkable data. The consideration of archaeological evidence from both Guerrero and Oaxaca will permit identification of similarities and differences through time and space in material culture, mortuary practices, settlement patterns, and architecture, perhaps revealing broad-scale cultural
affiliations connecting Pre-Columbian communities from both regions.

[9] Forum · MAYA ARTISTS AND THEIR AUDIENCES
Much of the literature focused on Maya art and architecture rests on assumptions regarding those who look and the locations and circumstances from which they view. This forum seeks to investigate the mechanisms at play in spectatorship inherent in discrete moments, places, and social positions. We will explore the agency with which Maya artists and audiences shaped art production from pre-Columbian times to the present, paying particular attention to the roles specific settings played in the way art has been consumed and created. We will ask how various internal and external forces impacted value systems and consumer demand for certain kinds of artistic products through history. In doing so, we will focus on the exact nature of public and private settings and the audiences implicated by each type of display. Interstitial contexts will also be considered to explore more closely who looks, who creates, and for whom. This will reveal the dialectic relationships between patron, artist, observer, and the site(s) in which this nexus of interaction takes place. In sum, we intend to analyze the continuities and shifts that arise from often-competing trends of cultural conservatism, pre-Columbian, colonial and postcolonial ideologies, and imperial versus capitalist market demand.

[10] Poster Session · COMPOSITIONAL ANALYSES AND SOURCING STUDIES IN ARCHAEOLOGY

[11] Poster Session · ARCHAEOLOGICAL CERAMICS

[12] Poster Session · LIFE, DEATH, DIET, AND DISEASE IN PREHISTORIC NORTH AMERICA

[13] Poster Session · TECHNICAL ANALYSES IN ARCHAEOLOGY

[14] General Session · PREHISTORIC TEXAS

[15] Symposium · WHAT'S HAPPENING ON THE FRINGE: TESTING A NEW MODEL OF CROSS-CULTURAL INTERACTION IN ANCIENT BORDERLANDS
Much of the conversation about cross-cultural interactions that takes place in the context of colonization, frontiers, and ancient borderlands is concerned with the language that archaeologists use to explore issues of power, identity, agency and cultural exchange and boundaries. Equally important are questions that address the permeability of boundaries and the (perceived) directionality of culture flows that archaeologists infer from material remains. In order to more clearly elucidate the processes that occur in these exchange situations we have developed a model of cross-cultural interaction that visually represents these simultaneous interactions in a comprehensive way. Our model explores the various ways in which people interact and what motivates their participation in cultural exchanges or what they reject. Because of its visual nature this model is applicable to a wide range of archaeological situations of cultural exchange and can generate a meaningful dialogue between scholars from different fields. The contributors in this symposium apply this model in different areas of the world and review its functionality within their own research contexts. In bringing together such a wide variety of comparative data from diverse regions we hope to add new insights to the conversation about prehistoric interactions in different types of borderlands.

[16] Symposium · MOVING ON: ANTHROPOLOGICAL PERSPECTIVES ON HUMAN MOBILITY
Mobility has become a dominant theme in archaeological research on hunter-gatherers. There is good reason for this: the ways people arrange themselves on physical and human landscapes are a nexus linking economy, social relations and technology. Moreover, mobility has robust implications for the structure of archaeological record. Archaeologists have adopted a series of approaches to studying mobility and its archaeological consequences based largely on the work of Binford, Kelly and other scholars. Although these approaches have been extremely fruitful in expanding understanding of ancient and modern foragers, thirty years on they have become routinized, achieving the status of "normal
The question before participants in the symposium is "what are we missing?" Are there other dimensions or scales of human mobility that play a significant role in structuring human behavior and/or the archaeological record? The symposium is open to a wide range of perspectives, from individual to aggregate, from local to global, from abstract to case-based. Like most good archaeological theory, novel perspectives on mobility are as likely to come from fields outside archaeology—primate and hunter-gatherer studies, foraging theory, modeling—as from within it.

[17] Symposium · SOCIETAL STABILITY AND ENVIRONMENTAL CHANGE: PAPERS IN HONOR OF KARL W. BUTZER
From the beginning of his career in academia, Karl W. Butzer has pursued indefatigable field and theoretical investigations on the evolution of human society and environment. Having worked in several parts of the world, his views transcended the regional level and have become global. His work has also transcended the ‘superficial’ bringing us data-driven and nuanced interpretations of human environment relationships. In so doing, his contribution to anthropology and archaeology has been tremendous, spanning the range from Paleolithic to highly complex societies. The legacy of his work has been developed further by his former students and colleagues, evolving into a sophisticated multidisciplinary approach in geoarchaeology, cultural ecology, and environmental archaeology. To celebrate his contribution, this session brings together scholars whose work has been influenced by K.W. Butzer's contribution to the broad topic of societal stability and environmental change in a variety of geographic regions and time periods, to discuss the latest developments of this complex topic.

(SPONSORED BY PALEOWEST ARCHAEOLOGY)
The Bureau of Reclamation’s $1.3 billion Navajo-Gallup Water Supply Project will convey water from the San Juan River to the eastern section of the Navajo Nation, southwestern portion of the Jicarilla Apache Nation, and the city of Gallup, New Mexico. The project corridor brackets the San Juan Basin in northwestern New Mexico, an archaeological-rich area that also contains numerous Traditional Cultural Properties and sites sacred to surrounding Native American tribes. Construction has triggered one of the largest archaeological salvage projects ever undertaken in the American Southwest. The complexity of the archaeological deposits in the San Juan Basin is just one challenge of such a project. The bigger challenge has been coordinating the mandates of cultural resource preservation laws, consultation with Federal, State, and Tribal entities, managing large volumes of data, and the implementation of a complex research design that frames all of the investigations within a broader theoretical framework. Since the fall of 2011, PaleoWest Archaeology has been tasked with finding solutions to these challenges. By necessity, the scale of inquiry constantly moves from analysis of individual artifacts and sites to the synthesis of regional occupation, and from individual construction zones to the project as a whole.

[19] Symposium · CHARACTERIZATION OF ANDEAN CERAMICS
Ceramic analysis using mineral and chemical approaches are becoming more frequent in Andean Archaeology allowing to build up a large data set about ceramic production and distribution in the Andes and South America at large. The aim of this session is to reach a global vision of current characterization studies of Andean ceramics and discuss present knowledge of manufacture and circulation of pots in the Andes at large. Session themes include production loci, paste types, expected mineral and chemical signatures, geological settings impacting research, and sampling strategies of ceramics and comparative materials. The session will also focus on the interpretation of the characterization data to reach a higher understanding of the organization of ceramic production, as a community of practice embedded in and influenced by social, political and economic networks.

[20] Symposium · ONGOING RESEARCH IN EURASIAN ARCHAEOLOGY
Archaeological research in Eurasia continues to challenge understandings of social complexity and redefine approaches to past interaction. This session brings together graduate and newly post-graduate researchers working in Eurasia across time periods and research questions, presenting their original research. Questions under discussion will range from (and extend beyond): approaches to mobility, community, foodways and human-nonhuman interaction, trade and valuation, urbanism, space and scalar imagination, embodiment and mortuary practice. The session aims to generate an active and fruitful
discussion among the upcoming generation of scholars in the field, based around mutually exciting issues in a multi-regional field that continues to provide innovative and provocative opportunities for research.

[21] Symposium · MOBILITY AND MIGRATION OVER MESOAMERICA IN CLASSIC AND POSTCLASSIC TIMES
Mesoamerican historic narratives emphasize migrations in the formation of Postclassic political centers. Those movements were probably part of long processes reorganizing local political entities just before the emergence of the Mesoamerican states that confronted the Spanish invaders. However, Postclassic migration stories raise several issues in their interpretation and are difficult to correlate to the archaeological evidence in large settlements. The session proposes to renew our approach to population movements in Mesoamerica during the Classic and Postclassic periods. Archaeologists tend to view settlements and cities as constituted of static social groups. However, regular circulation over territories and even social fluidity are aspects that partly determined, and may help elucidate larger, less frequent population movements. Mobility is envisioned as “…the likeliness or ability to make movements.” (Inomata 2004:179) periodically for subsistence or trade needs, for social (marriage) or even ritual (pilgrimage) requirements at a micro- or macro-spatial scale. Migration includes small and large population movements related to extra-ordinary events (political recompositions, conflicts, droughts…). We need to compare and combine sources, methods and insights evaluating their potential to further our sociological knowledge of prehispanic urbanization and city abandonment processes.

[22] Symposium · CONTRASTING PATTERNS OF COLLECTING, TREATMENT AND USE OF STEMS AND FIBER FOR CRAFTS IN HUNTER-GATHERER VERSUS HORTICULTURAL AND AGROPASTORAL GROUPS
Ethnographic and archaeological case studies can show patterns of acquisition and treatment of plants and animal fiber for making highly perishable craft objects, including basketry (matting, containers, etc.), nets, sieves, cordage, textiles, etc., possibly used in obtaining and producing food, for making weapons, clothing, adornments, or decorations, for example. Do the patterns of acquisition and treatment of these materials or the kind of objects produced differ among sedentary and non-sedentary hunter-gatherers, communities with an "intermediate" pattern involving hunting and gathering and horticulture, and nomadic and sedentary agro pastoral groups? Does archaeological data show that changes occur in these patterns during socioeconomic transitions (such as between the Mesolithic and the Neolithic in the Old World)? Although we are unlikely to find definitive, holistic answers to the above questions in this session, we invite case studies examining aspects of the "chaînes opératoires" of acquisition of materials, techniques, objects and their uses, in given socioeconomic contexts. We invite authors to consider whether their findings might be unexpected in another socioeconomic context, or rather are-or could be-omnipresent in groups of different socio-economic structures or age.

[23] Symposium · GIVING LATITUDE TO ALTITUDE (AND VICE-VERSA): THE ARCHAEOECOLOGY OF HUMAN SETTLEMENT IN EXTREME ENVIRONMENTAL SETTINGS
This symposium presents a comparative study of the archaeology and ecology of people living in high-altitude and high-latitude environments. The purpose here is to understand human adaptations to settings with analogous limiting mechanisms: namely extreme temperatures, dramatic seasonal and annual variation, and minimal biotic productivity. Contributors will examine case studies from different time periods, and different parts of the globe ranging from Beringia to the Bolivian Altiplano. Each paper presents, to varying degrees, a consideration of the ecological, technological, behavioral, and organizational variables that enabled human groups to occupy, settle, and thrive in these settings. Ultimately a more thorough understanding of the global diversity in the colonization of previously uninhabitable landscapes will provide insights on the nexus between human innovation, flexibility, resilience, and physical adaptation.

In April of 2013, members of the archaeological research community lost a significant benefactor with the death of Joseph L. Cramer. Over more than two decades Joe and his wife Ruth created major endowments at seven universities in the U.S. These endowments support research that focuses on the
search for evidence of the First Americans, and most of them have fostered strong geoscientific approaches. The goal of this session is to demonstrate some of what has been learned as a result of the Cramer endowments about North American Paleoindians and the peopling of the Americas, and thereby to assess the impact - present as well as past - of private support for archaeological research.

[25] Symposium · CULTURAL MEANINGS OF HEAD TREATMENTS IN MESOAMERICAN AND ANDEAN SOCIETIES
This symposium explores the emblematic notions of the head and its corresponding behavioral correlates in the enactment of body practices, as documented in the Mesoamerican and Andean material record. Both cultural spheres held—and still hold—body- and specifically head-anchored worldviews. Here, the head with its outer insignia held a prominent role in physical embodiment, destined to protect, to gain strength, to impersonate, to emulate sacred forces, to distinguish or simply to acquire native identity. Beyond life, heads and their material vestiges anchored ancestor veneration or could be used as powerful war trophies or relics. Priority is given to confronting different relevant iconographic and bioarchaeological data sets and to “emic” points of departure in conceptualizing the expressions of indigenous notions of the head and its vital components. The head practices to be explored in this symposium encompass a wide variety of behaviors, which range from facial cosmetics and infant cranial vault and face modifications, to posthumous head processing and head hunting. Two rounds of talks convey novel views and interpretations first of Mesoamerican, then on Andean head practices, recreating their broader meanings at the interstice between the self, the head and culture, and their mutual interaction.

[26] Symposium · LEVALLOIS TECHNOLOGY: ORIGINS AND SIGNIFICANCE
Stone artifacts referred to as “Levallois” cores and flakes continue to stir a substantial quantity of archaeological research across the Old World. Levallois products appear to have been produced by several different species of hominin, across large areas of Africa, Asia, and Europe. Current active research areas include the chronology of Levallois, technological convergence, significance for cognitive evolution, tool function and optimality, geographic distribution, hominin dispersals, and the potential role of this technology in wider questions of hominin evolution. This session aims to bring together a diversity of different perspectives on these issues, using data from fieldwork, artifactual studies, experiment, and comparative modeling.

[27] Symposium · ANDEAN PLAZAS: MATERIALITY, PERFORMANCE, AND SOCIETY
There has been a broad consensus among Andean archaeologists that plazas, as settings for public gatherings and activities, offer a privileged opportunity for studying the constitution of past societies. Given the extraordinary combinations of agents, actions, and material culture, community gatherings in the plazas were intense experiences that played a significant role in the reproduction of the ways in which communities understood themselves and the world around them. Archaeologists have employed different approaches to study plazas and experiences within them, putting emphasis on aesthetic, semiotic, communicative, performative, and/or experiential qualities. Despite the differences in emphasis, these approaches are largely complementary and thus can be combined in various ways to understand the role of plazas in the society. This symposium will bring together archaeologists working across the Andes (from Ecuador to Argentina, from the highlands to the coast) on different time periods (from the Formative to the Inka) to discuss theoretical and methodological questions raised by the relationships among the materiality of plazas, public performances, and society.

[28] Symposium · THEORETICAL APPROACHES TO ANALYSIS AND INTERPRETATION OF COMMINGLED HUMAN REMAINS
Commingled and disarticulated human remains present challenges for bioarchaeology and archaeology. These assemblages are typically underutilized in archaeological interpretation; they can provide useful information that when combined with archaeological context provide a more complete understanding of the lives of people in the past. In 2012, the session titled “Commingled and Disarticulated Remains: Working towards Improved Theory, Method, and Data” highlighted the variety and utility of this type of assemblage through an examination of method and theory. This session will focus on the application of social theory to commingled remains with focus on the cultural processes that create the assemblages as a way to better understand issues of ideology, meaning, social structure, agency, and lived experience in the past.
[29] Symposium · RESILIENCE, COLLAPSE AND SURVIVAL IN INTERESTING TIMES: VIKING AGE TO MEDIEVAL TRANSITIONS IN THE NORSE NORTH ATLANTIC CA. 1250-1450 C.E.
Migration and settlement of the North Atlantic during the Viking Age initiated a complex history of resilience and sustainable development in this part of Medieval Europe. The same society settled Iceland, the Faroe Islands, Greenland and northern Scotland; but changing environmental and socioeconomic conditions influenced their collapse or eventual survival into the High Middle Ages and beyond.

The climatic events of 1250-1300 C.E. were among the main causes for diverging economic pathways of these islands. Iceland and Faroes formed a long-lasting, sustainable society by participating in international dried fish and wool trade. Greenlanders, particularly affected by increased storminess and weather and sea ice unpredictability, adapted by increasing reliance on sea mammals to diversify subsistence strategies. Greenlandic Norse society was resilient, and able to survive another 200 years, until a new climate regime contributed to its collapse and disappearance around 1450 C.E. Diverging pathways of these North Atlantic economies, their resilience to environmental challenges, eventual success or collapse, and comparisons with cases from American Southwest are the subject of this session. Transdisciplinary lines of evidence from zooarchaeology, bioarchaeology, ancient DNA, isotopes, artifacts, AMS dating, geomorphology, tephrochronology, history, climatology, landscapes, biological ecosystem studies, architectural history, and religious studies will be presented by international teams.

[30] Symposium · RESEARCH, PRESERVATION, COMMUNICATION: HONORING THOMAS J. GREEN ON HIS RETIREMENT FROM THE ARKANSAS ARCHEOLOGICAL SURVEY
The Arkansas Archeological Survey has flourished as one of the country’s premier programs in archaeological research, site preservation, and public outreach under Tom Green’s energetic and enthusiastic directorship. To honor him on his retirement, friends and colleagues present papers highlighting themes that Green has emphasized in his career. These include seeing NAGPRA as opportunity for communication and dialog between archaeologists and Native Americans, using remote sensing technologies as effective and efficient tools for archaeological investigation and site preservation, and showing how Arkansas can benefit from and contribute to broader research directions in American archaeology. The antiquity of interaction and exchange systems, the causes and consequences of plant domestication, the development and variability of complex societies, and the struggles of disenfranchised peoples are several of these ongoing discussions. In publications and practice, Green has shown that cultural resource management, archaeological research, working with tribes and descendant groups, and relating archaeology to public audiences are interconnected activities that involve us all.

[31] Symposium · “PRECLASSIC MAYA CIVILIZATION IS NO LONGER A CONTRADICTION IN TERMS”: A SESSION IN HONOR OF NORMAN HAMMOND ON THE LAST FORTY YEARS OF PRECLASSIC MAYA RESEARCH (PART 1)
In this session, we celebrate the progress made on Preclassic Maya research in the last forty years and the legacy of Norman Hammond, who has focused most of his career as an archaeologist, teacher, and mentor in the study of the Preclassic Maya. He began his journey towards the origins of Maya civilization in 1968 with the excavation of Preclassic structures at Ceibal, and he then launched the Corozal Project in northern Belize. He spent many years in the field excavating Cuello, one of the oldest known Preclassic Maya communities. This 20-year-long project produced a large body of data and interpretations and a number of new scholars. The first part of the session is dedicated to how Norman Hammond’s work and the data from Cuello stimulated the first change in perspective on the Preclassic Maya since the Carnegie years. The second part of the session is dedicated to contemporary achievements in Preclassic Maya archaeology, including a few scholars whose career has been influenced by Norman Hammond as a teacher, colleague, or mentor. Our discussant will remark on the new knowledge accumulated in the last forty years of Preclassic Maya archaeology. The contributions will be published in an edited volume.

[32] Symposium · NEW INVESTIGATIONS AT THE HARRIS SITE, MIMBRES VALLEY, NEW MEXICO
The Harris Site is known for Emil Haury’s work there in the 1930s and its role in the definition of the Mogollon as a distinct Southwestern cultural group. New fieldwork began at the site in 2008, with the goal of investigating how households were organized, the degree of dependence on agriculture, and
social strategies in use during the Pithouse period (A.D. 550-1000). The papers in this symposium summarize the results of this recent work. These results point to some intriguing finds concerning household organization and social differences at Harris and have implications for our understanding of Pithouse period social dynamics in the Mimbres region.

[33] Symposium · LIGHTING DARK PASSAGES PART 1: CELEBRATING THIRTY YEARS OF JAMES E. BRADY’S CONTRIBUTIONS TO CAVE ARCHAEOLOGY
In 1981, Norman Hammond acknowledged that archaeology had little understanding of Maya cave use. The previous decade had seen the deaths of prominent Mayanists J. Eric Thompson, E. Wyllys Andrews IV, and Dennis Puleston who had produced some of the best work on cave archaeology of the Post War Period. Their deaths left cave research without direction. It was also in 1981 that James Brady began working at Naj Tunich, a large pilgrimage cave in Guatemala. Over the next three decades, Brady’s research and publications made him a central figure in developing Maya cave archaeology into, according to Stephen Houston, “one of the two best-studied traditions of subterranean archaeology in the world.” During this time, cave archaeology moved from being a peripheral pursuit to a well-recognized subdiscipline within Maya archaeology, quite often integrated into larger projects. This session assesses the contribution of Brady’s work within Maya studies and his influence on students and colleagues alike as well as presents new data and insights as the tradition continues to be elaborated.

[34] Symposium · ARCHAEOLOGICAL STUDIES IN SETTLEMENT ECOLOGY: RECENT ADVANCES FROM THE AMERICAS
Settlement ecology directly seeks to explain settlement patterns and to disentangle the cause and effect relationships of their arrangements. More specifically, settlement ecology strives to identify and to understand the relative importance of specific cultural, social, economic and environmental factors that directly influence the placement of sites, as well as subsequent changes in settlement organization across time and space. In this session, we assemble a diverse collection of archaeologists across the Americas, to explore the development of a settlement ecology approach to understanding prehistoric and historic settlement data. In particular, we invite participants to highlight successful applications of settlement ecology in archaeological studies, as well as associated methodological advancements (e.g. GIS, remote sensing, statistical applications, etc.). In particular, we aim to explore past settlement strategies as they relate to myriad interacting ecological/environmental variables (e.g., subsistence organization, land tenure, land degradation, resource availability, climate change), as well as cultural, ideological and sociopolitical factors (e.g., political collapse, spread of religion, political incursions, factionalism, state formation, alliances, etc.). Finally, we encourage participants to highlight the strengths and limitations of a settlement ecology approach, as well as its efficacy and future potential in the field of archaeology.

[35] Symposium · CURRENT MULTI-SCALAR RESEARCH IN SOUTH ASIAN ARCHAEOLOGY
South Asia has a deep and diverse archaeological record. This symposium will examine complexities and ancient technologies both in the Iron Age of South India and the Bronze Age of Northwest India, Pakistan, and the Gulf region. The fresh perspectives and new techniques being applied to the region are becoming increasingly important to the study of complex societies worldwide. Contributors to the session are working at many scales of analysis ranging from the close examination of one artifact class at a single site to regional surveys and re-imagining of regional politics.

[36] Symposium · PLACE AND SPACE IN A DIGITAL LANDSCAPE: NEW PERSPECTIVES ON ANALYZING AND SHARING GEOSPATIAL DATA IN ARCHAEOLOGY
This session continues the discussion begun by the Linked Ancient World Data Initiative (LAWDI), seeking to apply the concepts of “linked” and “open” data to the practical concerns faced by archaeologists, regardless of geographical or spatial focus. Spatial analysis is a well-established analytical tool for archaeological research. Rather than continue the debate about its value and limitations, we refocus the conversation toward two core themes. First, when used responsibly, spatial analysis has the potential to provide powerful interpretive frameworks rather than simply provide graphical representations. Archaeologists are using diverse digital methods to explore and analyze spatial data in new combinations, from which they are able to create more nuanced interpretations. Second, while digital publication and accessibility are becoming more common in scholarly research, the
implications for geospatial archaeological datasets have yet to be discussed in formal symposia. Relevant issues include “born-digital” publication, structuring data for reuse and interoperability, the value of open access, and the challenges of sharing data online. The papers in this session address both these themes, provide examples of how to apply the “linked” and “open” data concepts to archaeological research, and propose various methods for traversing the increasingly digital landscape of spatial analysis.

[37] Symposium · BORDERS AND BOUNDARIES IN ANCIENT MESOAMERICA
The delineation of borders and boundaries on household, community, polity, and regional scales is central to the construction and maintenance of corporate identity and social relations. Drawing from multiple approaches and lines of inquiry, this session investigates conceptualizations and enactments of borders and boundaries from the Formative to Late Postclassic periods in Mesoamerica. We examine social practices related to the establishment, enforcement, negotiation, contestation, and transgression of borders and boundaries, and explore the connections and disconnections between theoretical models and paradigms, archaeological assemblages, and emic understandings of spatial demarcation.

[38] General Session · THE ANDEAN WORLD FROM THE FORMATIVE THROUGH THE LATE

[39] Forum · ISSUES AND DIRECTIONS IN PHYTOLITH ANALYSIS
Over the past 40 years, phytolith analysis has become an integral part of archaeological and paleoethnobotanical research and has helped shed new light on many important topics. Despite the proliferation of phytolith studies, many aspects of phytolith research and training remain unresolved. Some of the issues that will be discussed in this forum include: How, or should the protocol for processing comparative materials, soils, artifact residues, and dental calculus become standardized and simplified? With so few academic and professional positions available, how do we train the next generation of phytolith researchers if students do not have an advisor who specializes in phytolith analysis? What steps can be taken to establish published regional comparative phytolith keys? Where is the field is headed? Researchers at various stages of their academic careers will offer their perspective on the problems they have encountered and provide insights into how archaeologists can move the discipline forward.

[40] Symposium · SUBSISTENCE AND LANDSCAPE CHANGE IN SUB-SAHARAN AFRICA
(SPONSORED BY SOCIETY OF AFRICANIST ARCHAEOLOGISTS)
African landscapes and humans have been coevolving since hominins shifted their dietary and foraging habits over a million years ago. However, modern humans’ mid-to-late Holocene intensification of foraging practices, implantation of novel domestic species, intentional landscape modification, iron-production activities, and movement to hitherto unexploited islands all created quantum shifts in the intensity of their interactions with regional biomes. Such anthropogenic trajectories of change in turn intersected with regional and continental scale processes of climate change to produce new configurations in ecosystems. Papers in this session examine various facets of such human interactions with species and environments.

[41] General Session · OLD WORLD EMPIRES

[42] Poster Session · PUEBLOAN SOUTHWEST

[43] Poster Session · AMERICAN SOUTHWEST

[44] Poster Session · RECENT RESEARCH OF THE ANIMAS PHASE BORDERLANDS OF THE NORTH AMERICAN SOUTHWEST
The Animas phase area of New Mexico was the focus of interaction among the Medio Period Casas Grandes culture to the south, the Salado and Black Mountain phase people to the north and west, and the El Paso phase Jornada Mogollon cultures to the east during the 13th and 14th centuries. Given that West Mexican and Mesoamerican influence filtering through this region fundamentally transformed Southwestern cultures, it is one of the most significant borderlands anywhere in North America. Recent
Researchers have recognized its importance, leading to a multi-year research program focused on 76 Draw and other Animas phase settlements. Results of this research are presented here with special emphasis focused on understanding regional interaction and evidence of integration within and beyond the Medio period world.

[45] Poster Session · APPROACHES TO UNDERSTANDING DESERT PAVEMENT QUARRIES
(SPONSORED BY STATISTICAL RESEARCH, INC.)
The posters in this symposium present the results of recent research at Fort Irwin and the National Training Center in the Mojave Desert of California. The research focuses on desert pavement quarries, which can extend for many hectares and include thousands of artifacts and features. These sites present challenges both in terms of the methods used to record them and the interpretations made from the data. The posters discuss novel ways of recording massive sites in the field, and present the results of a 10,000-acre survey at Fort Irwin.

[46] Poster Session · THE ANCESTRAL TEWA WORLD: RECENT RESEARCH IN NORTHERN NEW MEXICO
The archaeology of the northern Rio Grande region of New Mexico is undergoing a resurgence of interest, particularly of ancestral Tewa Pueblo sites that date from the thirteenth century through the Historic period. Research questions include: how do worldviews and a peoples’ relationship with the physical and cultural landscape change though time? How do disparate people come together to forge a new world? And how do people maintain these connections in the face of overwhelming external and internal forces? This poster session presents new research regarding subsistence, ceramic technology, pottery production and distribution, lithic procurement, and craft production that address these research questions and shed light on the creation of the Tewa world.

[47] General Session · SOUTHERN SOUTHWEST

[48] General Session · GREAT LAKES

[49] General Session · MAYA HOUSEHOLD AND COMMUNITY

[50] Symposium · COLLABORATIVE AND COMMUNITY ARCHAEOLOGY
This session focuses on archaeology projects involving varied and innovative collaborative efforts that focus on partnerships with local communities.

[51] Symposium · NEW ADVANCES IN THE SOCIETY AND ENVIRONMENT OF EARLY CHINA
Political system and divining rituals are always the big concerns in the anthropological study of Early China. Yet, issues regarding the more fundamental aspects of society, such as the production of food and daily-products as well as the redistribution of food resources have not attracted scholarly interests that they deserved. In addition, the impacts of production upon environment and how people react to society are often less interested in previous literature. Yet, new research employing various techniques and methodologies on these issues will not only improve our understanding of the basic conditions of Early China but also add much to the study of political system from a bottom-up perspective. This panel is inviting scholars and graduate students working on zooarchaeology, paleobotany, geoarchaeology, and the scientific study of production techniques (e.g., salt and agriculture) of Early China to present their recent works. The new information deriving from various approaches can also contribute to the exploration of synthetic theories and methods regarding the social organization and ancient economy from an archaeological perspective.

[52] General Session · ARCHAEOLOGY AND WATER IN MESOAMERICA

[53] Symposium · ANIMAL LIFE HISTORIES: INTEGRATIVE ZOOARCHAEOLOGICAL
APPROACHES TO INTERPRETATION OF INDIVIDUAL ANIMALS

Historically, zooarchaeologists have analyzed and interpreted animal remains at the assemblage level, rarely examining an individual animal's life history. Increasingly, questions about the lives of specific animals are being examined through analytical and interpretive approaches that can be viewed as a form of animal osteobiography. These osteobiographical approaches combine data gleaned from many areas of inquiry, including activity-, trauma-, and disease-related pathology, dietary provisioning through stable isotope analyses, and mortuary treatment. This symposium highlights methodological and theoretical research on individual animal life histories from a global perspective. Specific questions currently being addressed through these approaches will be identified, and the emerging methods used to answer them will be described and discussed. This advancing area of zooarchaeology has great potential to provide entirely new perspectives on human-animal interaction in the past.

[54] Forum · CULTURAL RESOURCES MANAGEMENT CHALLENGES ON MILITARY LANDS
(SPONSORED BY MILITARY ARCHAEOLOGICAL RESOURCES STEWARDSHIP (MARS) INTEREST GROUP)

The onus of cultural resources management and compliance for the Department of Defense (DoD) is a continually evolving challenge. As the third largest landowner among federal agencies, the DoD currently manages over 21 million acres of domestic lands, which contain over 111,000 recorded archaeological sites. This forum will highlight some of the most current and most persistent challenges in DoD archaeology, generating valuable discussion about effective solutions. In an interactive session with the audience, a range of topics will be discussed, including identification and treatment of Traditional Cultural Properties and Traditional Cultural Landscapes, mitigation of indirect effects on cultural resources, archaeology and renewable energy projects, programmatic solutions to inventorying large landscapes, application of predictive models, progressive data management, and managing unexploded ordnance risk in archaeological surveys.

[55] Forum · (RE-)DEFINING SPATIAL ARCHAEOMETRY

The purpose of this forum is to discuss the role of contemporary complex spatial data and spatial analyses of archaeological information within the fields of archaeometry and archaeoinformatics. Archaeometry, scientific research in archaeology, is generally defined as including research on absolute dating, geophysical prospecting, inorganic and organic materials analysis, and the building of spatial models. Archaeoinformatics, on the other hand, is defined as encompassing research on analysis and representation of archaeological data, including spatial information. Following the proliferation of complex geo-spatial data in archaeology, and a growing recognition of the spatial-embeddedness of much archaeological and archaeometric data, this forum explores the idea that the complexity of contemporary spatial data requires that the management and representation of the data, traditionally studied within archaeometrics, are integral to the research which uses it, traditionally carried out within archaeometry, and will work toward a new definition for spatial archaeometry which merges implicitly and explicitly spatial research in archaeometry and the practice of archaeoinformatics.

[56] Symposium · BORDERS AND FRONTIERS IN THE PUEBLOAN WORLD

The study of borders and related concepts, such as borderlands, boundaries, and frontiers, has seen a resurgence in the literature of the social sciences. Researchers in political science, geography, and sociology have all explored the nature and role of borders in our modern world, providing numerous examples of how nation-states, and people, interact. Of course, this situation is different for prehistoric societies, and previous societies would have viewed and interacted with “borders,” “boundaries,” and “frontiers” in a different light than we do as 21st century Euro-Americans. The researchers assembled for this symposium approach various methodologies used to study the dynamic nature of these frontier processes, which are those processes that act through, and past, state borders, and determine their utility for investigating the nature of borders and frontiers of the Chacoan system of the American Southwest. Concepts such as borders, borderlands, and frontiers, and the processes of interaction and hegemony will be discussed in relation to Chacoan political and social organization. These will be viewed at different scales, from the local scale of intra-community to large scale of Puebloan culture.

[57] Symposium · NATIVE PEOPLES, ARCHAEOLOGISTS, SACRED SITES AND HUMAN REMAINS IN LATIN AMERICA: SOME CASE STUDIES IN COLLABORATION

While NAGPRA transformed the relationship between archaeologists and Native Americans in the U.S.
affording protection to Native graves and resulting in the repatriation and reburial of human remains, there are no similar laws in much of Latin America and concerns about grave protection may seem minimal in many countries. Nonetheless, there are archaeological projects that have involved Native peoples in their research and there have been efforts at repatriation and reburial of human remains as well as working with Natives to protect ancient burials and address other indigenous concerns. This symposium is a space to gather information on relevant past projects in Latin America and to allow authors to evaluate their experiences.

[58] Symposium · WORLDS AT DIFFERENT SCALES: POPULATION INTERACTIONS AND DYNAMICS OVER TIME IN AFRICA (SPONSORED BY THE SOCIETY OF AFRICANIST ARCHAEOLOGISTS)
Africanist archaeologists, of necessity, approach their various topics of study drawing on data from several spatial and temporal scales. This session engages the great breadth of African archaeology, with papers covering periods from the Early to Middle Stone Age to the 19th century and describing work from seven different countries. It is united by its authors’ shared efforts to describe the different scales at which archaeological sites on the continent ought to be investigated so they might be fully understood, as well as the various audiences to which archaeological research can be communicated. In so doing, they describe the population dynamics and networks of interaction that helped shape the African past.

[59] Symposium · DAILY PRACTICE AND ENCULTURED EXPERIENCE: EXPLORING DOMESTIC LIFE AMONG THE MOCHE OF NORTHERN PERU
This symposium explores the cultural legacy of domestic practice on the north coast of Peru from the Initial Period through the Late Intermediate Period with a focus on the Moche culture. Household archaeology serves as a basis to examine some of Anthropology’s most important issues, including ethnicity, social inequality, ideology, cuisine, community organization, identity, and gender relations. Households not only reflect the underlying social structure of a given community, but also inform us about cultural practices that are generated and perpetuated by household members. Papers in this session will link household assemblages to wider social, economic, and political dynamics in Moche society. Additionally, contributors will explore the continuities and discontinuities observed in domestic activities on the North Coast through various time periods.

[60] Symposium · WHAT IS UP THERE? A CROSS-CULTURAL PERSPECTIVE ON THE FUNCTIONS, SYMBOLISMS, AND TRANSFORMATIONS OF HILLTOP SETTLEMENTS IN THE OLD AND NEW WORLDS
The term "hilltop settlement" is employed in archaeology as a common word to qualify any site located on a natural or artificial elevation. The multiplicity of dimensions included in this simple term (topography, function and symbolism among numerous others) is rarely examined. But despite this weakness of definition, the simple existence of a “hilltop site” has supported strong and determinant definitions of cultural traditions as well as chronologies and socio-political changes over the Old and New Worlds. This contradiction (a common generic word for a local specific interpretation) seems to be related, and created, by the absence of horizontal discussions, focused on this specific form of settlement process, and its practical and symbolical significance. The session will try to break scholastic and geographic divides by confronting methods, limits, lacunae, focuses, but also common questions and possibilities. Our discussion will be organized in three main topics: research contexts and perspectives; morphologies and characteristics of organization and space; and symbolism(s). The authors will present various study cases from the central Himalayas, Western Europe, Mesoamerica, and the Andean area.

[61] Symposium · “PRECLASSIC MAYA CIVILIZATION IS NO LONGER A CONTRADICTION IN TERMS”: A SESSION IN HONOR OF NORMAN HAMMOND ON THE LAST FORTY YEARS OF PRECLASSIC MAYA RESEARCH. PART 2
In this session we celebrate the progress made on Preclassic Maya research in the last forty years and the legacy of Norman Hammond, who has focused most of his career as an archaeologist, teacher, and mentor on the study of the Preclassic Maya. He began his journey towards the origins of Maya civilization in 1968 with the excavation of Preclassic structures at Ceibal, then launched the Corozal Project in Northern Belize. He spent the most years in the field excavating Cuello, one of the oldest Preclassic Maya communities known. This 20-year-long project produced a large body of data and
interpretations and a number of new scholars. The first part of the session is dedicated to how Norman Hammond’s work and the data from Cuello stimulated the first change in perspective on the Preclassic Maya since the Carnegie years. The second part of the session is dedicated to contemporary achievements in Preclassic Maya archaeology, including a few scholars whose career has been influenced by Norman Hammond as a teacher, colleague, or mentor. Our discussant will remark on the new knowledge accumulated in the last forty years of Preclassic Maya archaeology. The contributions will be published in an edited volume.

[62] Symposium · ICONOGRAPHY OF THE GULF COAST

Native peoples of the Gulf Coast comprise a unique regional identity manifest in shared social structures, technology, political organization and notions of the sacred. At the foundation is the Pre-Columbian past, an ancient history stretching in time from its civilization’s roots among the Formative Olmec to the arrival of the Spaniards on the Veracruz coast in the Sixteenth Century. Our session brings together an international group of the iconographers whose work focuses on the Mexican Gulf Coast. Papers will cover diverse cultural regions, ranging in time from the Formative to Contact periods. We believe that a focused regional approach will give way to new understandings of patterns of interaction, continuity, and change.

[63] Symposium · FEEDING TEOTIHUACAN: INTEGRATING APPROACHES TO STUDYING FOOD AND FOODWAYS OF THE ANCIENT METROPOLIS

Over a century of intensive investigation at both the core and periphery of Teotihuacan has produced a wealth of knowledge on the ancient metropolis. Diverse projects are revealing a picture of Teotihuacan as a socially complex multi-ethnic state with a far-reaching interaction network. In the present session, we aim to bring together scholars and data from multiple contexts across Teotihuacan to paint a holistic understanding of ancient food and foodways of the precolombian metropolis. Dietary practices and subsistence strategies influence and are influenced by multiple aspects of human societies, including social-environment interactions, political-economy, class, and identity. A better understanding of the foods and foodways of Teotihuacan, therefore, will enhance our knowledge of the ancient state across multiple arenas. This session attempts to foster an integrated discussion on Teotihuacan utilizing paleobotanical, zooarchaeological, iconographic, bioarchaeological, ceramic, and residue analyses. Such dialogue creates a renewed understanding of the complex links between food and culture, subsistence and economy, and consumption and identity.

[64] Symposium · ESTABLISHING A BIOARCHAEOLOGY OF COMMUNITY

Bioarchaeology has made prodigious methodological and theoretical progress on reconstructions of identity, social status, and familial relationships through such avenues as artificial cranial modification to understand ethnic identity within a polity, age/sex-specific distinctions to recognize social classes or labor groups, and strontium isotope analyses to distinguish individual migrants among larger populations. While many prior bioarchaeological studies relied on genetic relationships, physical proximity of burials and associated cultural items, or body modifications, the larger impact of this research is that scholars have begun to create a bioarchaeology of community. Human skeletal remains are then understood as more than just physical bodies, but as groups of people who shared some kind of past connectedness, which could have included, but is certainly not limited to ethnic groups, social classes, residential blocks, religious affiliations, and people with consanguine, affinal, and other kinds of kinship. In order to address ideas of community and expand these methodological and theoretical concepts within bioarchaeological studies, this global symposium discusses the possibilities and limitations with identifying different communities, how scientists who study human skeletal remains address and identify the concept of “community” in their research, and how the field of bioarchaeology contributes to these tasks throughout the world.

[65] Symposium · CYBER-ARCHAEOLOGY IN THE MIDDLE EAST - METHODOLOGIES ON THE NEW FRONTIER OF DIGITAL FIELDWORK

The use of digital methods in archaeology continues to be an increasingly important part of field research. The decrease in cost of different technologies has coincided with a greater awareness of the utility of a number of digital techniques that have yielded new analytical lenses for the archaeological record. This emerging frontier is especially evident in research in the Middle East where these technologies are being used to provide a number of new data sets that supplement our knowledge of dating, site formation
processes, raw materials sourcing, amongst other important lines of information that until recently were not easily accessible. The total life cycle of these data, from collection techniques, manipulation, curation, and dissemination has led to research methodologies that have produced new avenues for archaeological research. This session seeks to look at the different kinds of inquiry that have arisen from the shift within archaeology to answer age-old questions in the Middle East. This includes new methods for analysis using tools such as digital chemistry and imaging, new data management techniques, and advanced environments for presenting research through the web or visualization theaters.

**[66] Symposium · LEGACIES OF THE MIMBRES FOUNDATION: SHAPING THE FUTURE OF MIMBRES REGION ARCHAEOLOGY**

In the mid-1970s the Mimbres Foundation, a private non-profit headed by Steven LeBlanc, began a research project in the Mimbres region that has had momentous and long lasting impacts. Almost no professional archaeological work had occurred since the large expeditions of the 1930s, while looting of sites for the spectacular painted pottery had continued unabated. Many archaeologists considered Mimbres archaeology essentially destroyed, but LeBlanc demonstrated otherwise. The Mimbres Foundation showed that scientifically important remnants of Classic Mimbres pueblos survived intact and that prehispanic occupations of the region were much longer and more complicated than previously imagined.

On this 40th anniversary of the initiation of Mimbres Foundation fieldwork, we assess the impacts of the Foundation’s research. We address the current state of Mimbres archaeology and evaluate how our knowledge has changed over the past decades. We examine the role of non-profit organizations, in particular the Mimbres Foundation. We address the social and environmental contexts of food procurement and production, the changing diversity and organization of Mimbres communities, the social contexts of pottery manufacture and iconography, and relationships with regions beyond the Mimbres, and we evaluate how the Mimbres Foundation provided the essential base for subsequent research in the Mimbres region.

**[67] Symposium · ARCHAEOLOGY, DEATH, AND CHANGE IN ANCIENT ARABIA**

The Bronze Age in Arabia represents a remarkable period of growth in social complexity and interregional interaction. A vast, pan-Gulf exchange network rapidly spread over thousands of kilometers and involved both land- and maritime-based interactions between relatively diverse cultures. In Arabia mortuary monuments and their contents are some of the strongest lines of evidence we have to understand the people who lived in these regions. These landscapes of death reflect many aspects of human interaction including sociopolitical change and complexity, population identity, population movement, and the transmission of ideas and technology. Analysis of human skeletal material also contributes information regarding changing subsistence practices and lifestyles, and occasionally even the transmission of new diseases.

Using the 3rd millennium B.C. as the focal point, this symposium brings together researchers working at sites and with materials from in and near to Arabia. The contributed papers will explore the diversity of mortuary practices, biological and cultural identity, health, and life experience in Arabian Bronze Age as well as the periods immediately before and after. This symposium will provide a forum for researchers to hear about regional similarities and differences as well as identify common areas of interest, new methodology, and topics for future collaboration.

**[68] Symposium · STEWARDSHIP, PUBLIC EDUCATION, AND PRESERVATION: PROMOTING THE VALUE OF ARCHAEOLOGICAL COLLECTIONS AND RESEARCH**

The third annual symposium sponsored by the Committee for Museums, Collections, and Curation highlights positive efforts by archaeologists within and outside of curational facilities to demonstrate the value and importance of archaeology to broad audiences and funders. More than basic principles of archaeological ethics, Stewardship, Public Education, and Preservation promote the interests of the entire archaeological profession. In an era of severe budget cuts and sequestration we are increasingly pressed to justify the relevance of our discipline, museums, and repositories to law makers and tax payers. As stewards of the archaeological record, all archaeologists are obligated to use their specialized knowledge to promote understanding and preservation of irreplaceable collections. Museums and
repositories have long been at the forefront of public education, enlisting both public and private support for the discipline. Yet, the battle for public opinion and the need for advocacy belong to the entire profession, particularly as our museums and repositories are forced to reduce or refuse collections and decrease curation staff. Papers presented in this symposium consider how archaeologists interact with broad audiences to shape public opinion and public policy.

[69] Symposium · EARLY HUMAN OCCUPATION DURING THE ICE AGE IN THE AMERICAS: NEW DIRECTIONS AND ADVANCES
The symposium aims to review the main developments that have been the subject of the settlement of Americas in the last 10 years. This advance allowed the generation of new models of settlement, increased the number of sites and regions currently under investigation and increased the 14C dates by high-resolution methods such as AMS. The diversity of environments and varied cultures that occupied both North America and South America since the end of the Pleistocene demonstrate the complexity of this issue and make us think that perhaps the beginning of the settlement dates back to the Last Glacial Maximum. The aim of this symposium is to bring together researchers from different regions of the Americas to discuss the evidence we have on the settlement of our continent. We seek researchers to present, analyze and discuss the major advances that have been achieved in the region investigated. The main topics include: settlement patterns, lithic technology, extinction of Pleistocene fauna, cultural diversity during the settlement, genetics and high-resolution chronology. The papers include different geographical regions such as North-West-Central-and Eastern of North America, Central America (Mexico, Panama) and South America (Colombia, Ecuador, Peru, Bolivia, Chile, Argentina, Uruguay and Brazil).

[70] Symposium · LIGHTING DARK PASSAGES PART 2: CELEBRATING 30 YEARS OF JAMES E. BRADY’S CONTRIBUTIONS TO CAVE ARCHAEOLOGY
In 1981, Norman Hammond acknowledged that archaeology had little understanding of Maya cave use. The previous decade had seen the deaths of prominent Mayanists J. Eric Thompson, E. Wyllys Andrews IV, and Dennis Puleston who had produced some of the best work on cave archaeology of the Post War Period. Their deaths left cave research without direction. It was also in 1981 that James Brady began working at Naj Tunich, a large pilgrimage cave in Guatemala. Over the next three decades, Brady’s research and publications made him a central figure in developing Maya cave archaeology into, according to Stephen Houston, “one of the two best-studied traditions of subterranean archaeology in the world.” During this time, cave archaeology moved from being a peripheral pursuit to a well-recognized subdiscipline within Maya archaeology, quite often integrated into larger projects. This session assesses the contribution of Brady’s work within Maya studies and his influence on students and colleagues alike as well as presents new data and insights as the tradition continues to be elaborated.

[71] Symposium · PALEOLITHIC PARADIGMS: PAPERS IN HONOR OF GEOFFREY CLARK
Geoffrey Clark’s 40-plus year career as a scholar and mentor has spawned numerous significant contributions to Paleolithic research. The geographic scope of his work arcs from Atlantic Europe to the Near East. He has been many things to many people: an exemplar of erudite hunter-gatherer ecological studies; a critical analyst of the conceptual frameworks affecting paleoanthropology; and an unwavering advocate for the role of science in public policy and education. These papers, presented by students and colleagues, reflect the broad impact of his career.

[72] Symposium · TECHNOLOGY AND TRADITION IN MESOAMERICA AFTER THE SPANISH INVASION
The introduction, redesign, and adoption of new technological systems following the Spanish invasion produced radical changes in ecology, craft, and identity for native peoples of Mesoamerica. Research on cultural transformations following the Spanish invasion have wrought an alternative perspective that emphasizes how native groups played central roles in mediating asymmetrical power relations over the last 500 years. Yet, comparatively little scholarly attention has focused on technological change and its relation to modernity. Significant technological disparities often persisted among socioeconomic groups, even though the political-economic complexity of Mesoamerican societies was comparable to Spain’s in the sixteenth century. We examine material evidence of multi-scalar and multi-directional technology transfer in cultivation and husbandry of new domesticates, animal traction, use of water lifting, mechanical and wheeled devices, weaving and dyeing cloth, fermentation, adoption of firearms, the replacement of
stone with metal tools, and changes in the technological styles of ceramic and glass containers. Presenters demonstrate how technological differentiation in the past underpins constructions of modernity in the present.

[73] Symposium · MARKING THE LAND: HUNTER-GATHERER CREATION OF MEANING WITHIN THEIR SURROUNDINGS
The land is full of meaning for hunter-gatherers. Much of that meaning is inherent in natural phenomena and characteristics of the environment, but some of it is created or enhanced by modifications to the landscape that hunter-gatherers themselves make. Such modifications may be intentional or unintentional, temporary or permanent, and they range from simple, rational, and practical signs that provide guidance and information to elaborate, symbolically significant, ceremonially or ritually visited and maintained locales. The aim of this symposium is to investigate this wide range of hunter-gatherer modifications to their surroundings, to see under what conditions they invest time and effort in such landscape marking, and what determines the extent to which these modifications to their surroundings are, or are not, symbolically charged and elaborated.

The period between 1945 and 1970 in American Archaeology witnessed a dramatic increase in the number of archaeological investigations. Armed with new tools, such as radiocarbon dating, geophysical survey, and flotation-processing of botanical remains, archaeologists were able to flesh out regional chronologies, focus archaeological investigations, and better understand human-plant-animal relations, which allowed archaeologists to move from describing and classifying past human cultures to explaining and interpreting past human behavior. This symposium examines the careers of archaeologists who worked during this period, following the end of New Deal Archaeology and before the advent of the National Historic Preservation Act and the rise of Cultural Resource Management. The careers examined here include both professional and avocational archaeologists, who worked for state and federal agencies and academic institutions. Many of the archaeologists examined here played significant roles during this period, while others, played less humble roles; however, their contributions were no less important. These archaeologists made significant strides to the discipline of archaeology, often on shoestring budgets. The contributions of these archaeologists had a significant impact on our discipline, which is still felt today.

[75] Symposium · INTEGRATED HISTORICAL ECOLOGY OF HUMAN ECODYNAMICS: AN APPLIED ARCHAEOLOGY FOR FUTURE EARTH
The impacts of global environmental change will present fundamental challenges and opportunities for global sustainability over the next few decades. International efforts to co-design and deliver an informed response from the scientific community are currently being mobilized and coordinated by Future Earth. The central role of long-term perspectives on social-ecological dynamics in such responses is advocated by several multidisciplinary research communities, including IHOPE and GHEA. IHOPE (Integrated History and Future of People on Earth) is a global network of archaeologists and other scientists that uses historical ecology’s integrated approach to study combined human and Earth system history, ultimately to inform global sustainability efforts. IHOPE’s long-term, human-scale perspective is intended as a corrective to models based on Earth system science that exclude knowledge of the world drawn from the social sciences and humanities and from communities of practice. With a similar intellectual scope, GHEA (Global Human Ecodynamics Alliance) is a multidisciplinary organization of scholars, educators, students, and policy makers that promotes problem-orientated research, education, and application of coupled social-ecological systems across spatial and temporal scales. This session will consider, discuss, and articulate the key messages that archaeological research has generated that can explicitly contribute to the Future Earth initiative.

[76] Poster Session · ARCHAEOLOGICAL PRACTICE, COLLABORATION, INTERPRETATION, AND OUTREACH

[77] Poster Session · ISSUES IN MANAGING ARCHAEOLOGICAL SITES, ARTIFACT
Most college and university students’ first exposure to archaeology is through an undergraduate introductory archaeology course, and it is often this setting that sparks initial interest in the discipline. Teaching archaeology to undergraduates involves cultivating that interest within students whose futures may include work in the cultural resources management sector, environmental sciences, museums, laboratories or graduate training in archaeology. Many, however, will pursue some other profession while hopefully retaining a philosophy of stewardship and advocacy for archaeology. Given the important groundwork that is established in undergraduate education, it is well worth considering how basic archaeological methods are effectively instilled through all levels of undergraduate instruction. The Middle Atlantic has a strong tradition of training and mentoring archaeology students, with more than fifty undergraduate programs in the region. Featuring a diverse range of field, classroom and laboratory projects and activities from within the Middle Atlantic region, the session models best practices for experiential learning and pedagogical strategies for teaching basic archaeological skills in classroom, field and lab settings within the region. It highlights ways in which applied archaeology, interdisciplinary studies, virtual modeling, and practical experiences in the field, archives, classroom and laboratory can form unforgettable, life-changing experiences.

The Digital Index of North American Archaeology (DINAA) has developed interoperability models for archaeological site databases created by State Historic Preservation Offices (SHPOs) and similar entities in the eastern United States (DINAA is funded by National Science Foundation grants #1216810 & #1217240). The core research team includes members from the University of Tennessee, the Alexandria Archive Institute (Open Context), and Indiana University. DINAA’s goals include: (1) only distributing non-sensitive site characteristics related to culture history, investigative strategies, and information quality, and only using coarse-grained visualizations that cannot allow site location rediscovery; (2) facilitating research queries of archaeological site descriptions across multi-state regions through a flexible and extensible, web-based ontology system that allows functional relationships between site terminologies to be recognized, while still retaining the characteristics of the original definitions; (3) allowing researchers to generate coarse-grained (ca. 20 km raster grid) visualizations of distributions of archaeological site descriptors on a landscape scale that is standardized and not forced into irregular county-level boundaries; (4) advocating for stronger archaeological database and geospatial competencies with completely open datasets and instructions that leverage open-source applications to share the research potential of publicly produced CRM data with research, student, and public audiences.

American Landscapes is a publication project created and funded by Oxbow Books/David Brown Book Company that is designed to present a series of lavishly illustrated volumes exploring the landscape history of the North American continent. Each volume will provide a comprehensive and accessible narrative aimed at the informed reader, presenting an up-to-date review of the latest research from archaeology, anthropology, historical studies and the environmental sciences, which will also provide a guide to the detailed literature. The aim is to produce an expert overview – from a holistic landscape perspective – of the history and changing land use of particular areas/regions or archaeological/historical themes across a wide timeframe in the United States and Canada. In this poster symposium, we will present the major themes and subject areas we are exploring, illustrated by case studies forming individual contributions to the symposium, which form the basis of volumes currently in preparation.
[83] Symposium · MIXTEC POLITIES: VARIATIONS, DEVELOPMENTS, AND TRANSFORMATIONS SPANNING THE POSTCLASSIC TO COLONIAL PERIODS

The Mixteca of greater Oaxaca was home to large populations and influential political and religious centers during the Postclassic period. Increasing archaeological attention to the Mixteca over the past decade using new methodologies and interpretations provides the opportunity to reassess our understanding of Postclassic Mixtec polities, or yuhuitayu, including their variation, development, and transformation. This session gathers papers investigating the many facets of Mixtec polities during the Postclassic and early Colonial periods, including variability in their form, social organization, interregional connections, economic underpinnings, and leadership. Papers explore the yuhuitayu in the regions of the Alta, Baja, Costa, and Guerrero and examine elements of change and continuity among Mixtec polities following the Spanish entrada.

[84] General Session · SOUTHWEST ASIA

[85] Symposium · RISE AND RESISTANCE: COMPLEX POLITIES AMONG ISLANDS AND COASTS
(SPONSORED BY SAA ISLAND & COASTAL ARCHAEOLOGY INTEREST GROUP)

Under what conditions and circumstances do complex polities arise in island and coastal settings? Similarly, why do they emerge on some islands, but not on others in a given region? Do such societies follow some fundamentally different historical trajectory than the familiar patterns observed for interior riverine agricultural groups? Often, explanations regarding the development of, and resistance to, such changes in social organization appeal to the high productivity of marine resources in island and coastal environments. We ask the participants in this symposium to go beyond economic explanations and explore how ritual, politics, and the sociality of daily life by the sea either fuel the resistance to or aid in the transformation of these societies from autonomous villages to integrated hierarchical/heterarchical polities. Our goal in this symposium is to provide a global examination of groups that have either undergone or have resisted such transformations in an effort to explore both the historically contingent factors, as well as any cross-cultural regularities among these societies. These perspectives will not only provide important information regarding the nature of such transformations in island and coastal environments, but also how such circumstances may be either different from or similar to their mainland interior counterparts.

[86] Forum · ETHICS IN CULTURAL RESOURCE MANAGEMENT
(SPONSORED BY COMMITTEE ON ETHICS)

As the majority of working archaeologists are employed in some form of cultural resource management, adherence to the SAA Principles of Archaeological Ethics is of paramount importance in documenting and preserving our shared cultural heritage. Cultural resource management archaeologists face numerous challenges balancing professional responsibilities to the Society’s ethical principles, the archaeological resource under investigation, their clients and individual project budgets, the laws of the state and/or nation in which the research is conducted, and the interests of descendant populations and the general public. The SAA Principles of Archaeological Ethics dictate that, “Given the destructive nature of most archaeological investigations, archaeologists must ensure that they have adequate training, experience, facilities, and other support necessary to conduct any program of research they initiate in a manner consistent with…the principles and contemporary standards of professional practice.” This forum is intended to provide an open discussion regarding specific ethical challenges facing cultural resource management archaeologists, both in the United States and around the world, and to foster the exchange of ideas on ethical guidance targeted towards the unique challenges of cultural resource management archaeology.

[87] General Session · ARCHAEOLOGY ON PUBLIC LANDS

[88] Symposium · CONFLICT, ARCHAEOLOGY AND THE PRESS
(SPONSORED BY MEDIA RELATIONS COMMITTEE)

Every society has a past which has left remains which interest archaeologists. Most societies have experienced some sort of conflict, which interests the press. Occasionally individuals or groups have used a conflict and resulting threats to the remains of the past as an opportunity to promote personal or social
agendas. This session will examine how the press has addressed a variety of archaeological concerns in areas of past or current conflicts from around the world.

[89] General Session · EUROPE DURING THE BRONZEAGE, IRON AGE, AND VIKING AGE

[90] General Session · NEW WORLD ROCK ART

[91] General Session · HIGHLAND MEXICO

[92] General Session · EURASIA

[93] General Session · BIOARCHAEOLOGY IN LATIN AMERICA

[94] General Session · MEDIEVAL AND POSTMEDIEVAL EUROPE

[95] General Session · ARCHAEOLOGY OF NATIVE AMERICAN SOCIETIES IN TEXAS

[96] Electronic Symposium · GETTING BACK TO SAVING THE PAST FOR THE FUTURE: HERITAGE EDUCATION AT A PROFESSIONAL CROSSROADS
(SPONSORED BY PUBLIC EDUCATION COMMITTEE)

In 1988, the Society for American Archaeology initiated the “Save the Past for the Future” Project to curb vandalism and destruction of archaeological resources, and provide for public education. Federal and state agencies and partners responded with an impressive variety of programs such as the Passport in Time program and Project Archaeology. The SAA’s Public Education Committee (PEC) became not only a clearing house for heritage education, but launched a number of successful internal and external initiatives, through the dedicated service of over 50 members. Despite the successes of the PEC, Board support for the large, active group waned and in 2008 reduced the size to 15 rotating members, in keeping with new SAA committee policy. During the same period environmental educators formed the North American Association for Environmental Education (NAAEE). The NAAEE has state chapters to promote environmental education within states, establish best practices, and holds an annual meeting that attracts 1000 educators. Today the future of heritage education is threatened because it has no organization to support the efforts of a large group of heritage education professionals. This session will explore the development of heritage and environmental education and examine the possibilities for future professionalization of heritage education.

[97] Forum · BUILDING A TACTICAL AND STRATEGIC TOOLKIT FOR INDIGENOUS HERITAGE STEWARDSHIP
(SPONSORED BY INTELLECTUAL PROPERTY ISSUES IN CULTURAL HERITAGE (IPINCH) PROJECT)

Despite continuing technical and legal advances in the protection and mitigation of biophysical and sociocultural heritage, many stewards of Indigenous peoples’ heritage struggle with dominant Western institutions, practices, epistemologies, and so on. Particularly vexing questions and issues surround the conservation of intangible sociocultural heritage and intellectual property embedded in ancestral territories, ecosystems, and heritage landscapes and sites. Although problems persist, individual stewards, the stories they tell, and the organizations they have built are bearers of knowledge and wisdom concerning good ways forward. As one part of a continuing effort to share recommended strategies and practices, this forum brings together Indigenous heritage stewards and their allies to discuss what stewards need to know and do to be effective. What are the key ingredients—methods, concepts, strategies—of indigenous heritage stewardship? What are the most important lessons learned thus far? How can these lessons be taught to the next generations of stewards?

[98] Forum · BRIDGING THE GAP: PROTECTING ARCHAEOLOGICAL RESOURCES IN THE AGE
OF SHALE GAS DEVELOPMENT

Shale gas is expected to produce more than 1.6 million jobs by 2035. It has increased America’s energy self-sufficiency and fueled economic growth. Yet a significant amount of shale gas development takes place on private land with private funding and is exempt from the National Historic Preservation Act. The SAA has estimated that more than 195,000 sites could be at risk in just nine shale formations. With no cultural resource reviews required, unfortunate outcomes are already coming to light, such as the partial destruction of a Native American site in Pennsylvania and the disturbance of a cemetery near a historically black coal camp in West Virginia. Stakeholders are now partnering to devise solutions. The Gas and Preservation Partnership (GAPP) serves as a mechanism for collaboration between the preservation community and the shale gas industry to establish best practices that balance responsible shale development with our collective interest in preserving cultural and historic resources. In this forum, GAPP leaders will discuss their individual perspectives and GAPP’s efforts to influence public policy. The session will engage participants in a dialogue about developing model best practices and devising strategies for industry engagement.

[99] Forum · PLANT DOMESTICATION: MORPHOLOGY, GENETICS, AND SOCIAL CONTEXT

Certain staple plants have become important globally. The histories of human-plant interactions are studied by archaeobotanists and geneticists alike, tracing this important process from wild to domestic. Despite much work, scholars continue to grapple with the concept of domestication, especially with respect to human engagement. Does the term ‘domestication’ constrain or help our understanding of human-plant relations? Is there a process that may be called domestication? Can archaeobotanists define it in a way that is useful with our data? In studying this process, can we learn about both the plant and the people? Should we focus on the biological definition of morphological change, or focus on the genetic changes of these plants? What do we know about the social context of the process? Scholars of rice, millet, maize, wheat, and Chenopodium will present their data and views on domestication from their specific plant’s perspective. Presentations will provide current data from two major orientations, genetics and morphology. Discussion on domestication and its productivity in archaeobotany will then be opened up to all at the forum.

[100] Forum · SURVEYING THE AMERICAS

Discovering the Archaeologists of the Americas is a planned project that intends to collect, analyze and share information about archaeological practice in North, South and Central America and the Caribbean. The project will gather demographic information and explore the relationship between training opportunities, employers’ needs, and working archaeologists’ qualifications. It will examine relationships between archaeologists of one state or country working in another and will look at how to build capacity within countries. The SAA Task Force on Discovering the Archaeologists of the Americas is planning a pilot project, in advance of a full-scale survey, to investigate these questions. In this session, we talk about previous efforts to survey the profession, and open up the floor to discuss key variables that need consideration, as we consider this ambitious project to examine how professional archaeology is structured and delivered across the Americas.

[101] Forum · USING TDAR (THE DIGITAL ARCHAEOLOGICAL RECORD) FOR MANAGEMENT, RESEARCH, AND EDUCATION—LESSONS LEARNED
(SPONSORED BY THE CENTER FOR DIGITAL ANTIQUITY)

Digital data present opportunities for data search and discovery, examination, synthesis, and integration not available with documents or data that exist only on paper. Digital data and documents also present challenges that must be overcome to ensure effective and efficient access and preservation. This forum gives participants the opportunity to speak briefly about important lessons they’ve learned in their innovative use of digital data and documents for resource management, research, teaching, and other kinds of public outreach. Our panel members include academic, agency, and CRM archaeologists with regional expertise in the US and abroad. Their experiences highlight the variety of ways in which the Digital Archaeological Record (tDAR), a repository of digital archaeological data, is used for comparative analyses and synthetic research, the management of archaeological information, access and preservation projects, and other activities.

[102] Poster Session · BIOARCHAEOLOGY IN THE OLD WORLD
[103] Poster Session · BIOARCHAEOLOGY IN MESOAMERICA AND SOUTH AMERICA

[104] Poster Session · ARCHAEOLOGY OF SOUTH AMERICA

[105] Poster Session · ANDERE MORTUARY PRACTICES

[106] Poster Session · NEW RESEARCH IN MEDIEVAL ARCHAEOLOGY
This symposium presents new and on-going research in medieval archaeology. The studies included draw from a variety of data sources and employ a diverse array of methods, including excavation, pedestrian survey, folklore, documentary/literary analysis, network analysis, and osteoarchaeology. Area foci include early medieval Ireland and medieval France.

[107] Symposium · DIGITAL MODELLING AND ANALYSIS IN ARCHAEOLOGY
The computer revolution is perhaps the most significant development in archaeological science since the advent of radiocarbon dating. Computational analyses are common to the point of ubiquity, in the form of complex statistical analyses, Geographic Information Systems, remote sensing and geophysics, etc. And yet, one of the most under-utilized opportunities in archaeological analysis is the digital reconstruction and representation of archaeological materials/sites and the analyses that these afford.

[108] Symposium · DYNAMICS OF TRADE AND SOCIOPOLITICAL DEVELOPMENT IN WEST AFRICA
(SPONSORED BY SOCIETY OF AFRICANIST ARCHAEOLOGISTS)
The last millennium witnessed a series of dramatic sociopolitical transformations among societies across West Africa. Western historiography concerning these transformations was traditionally preoccupied with issues of European contact, trade (especially the slave trade) and political domination; some attention was paid to the histories of ‘medieval empires’, but the characteristics and dynamics of these political forms were not well understood. Over the last thirty years, archaeological research in both the Sudanic and forest zones of West Africa has complicated this narrative, highlighting the indigenous origins of urbanism and complex political systems in the region, and emphasizing the strategies used by African societies to deal with the opportunities and dangers of contacts from beyond the continent. Papers in this session continue this process of examining the dynamics of sociopolitical development during the last thousand years. They do so by highlighting the diversity and complexity of political systems and economic networks in space and time; by emphasizing the ways in which African communities creatively maintained identities at different scales before and after European contact; and by extending research into areas of West Africa hitherto little known. Papers include research from anglophone and francophone West Africa, and from significantly different cultural and political milieu.

[109] General Session · EARLY PREHISTORY IN AFRICA

[110] Symposium · SESSION: VERNACULAR ARCHITECTURE OF THE PRECOLUMBIAN AMERICAS
At the heart of a study of vernacular architecture is an emphasis on ordinary people and their built environments. While often sidelined by interests in more monumental and elite architectural forms, an archaeology of vernacular architecture centers on the ways in which the everyday was pivotal in the making and meaning of social and cultural dynamics. Rather than mere containers for artifacts or passive backdrops for the on-goings of social life, people and their dwellings mutually influence each other as part of historically embedded practices. While the use of the term ‘vernacular architecture’ tends to be associated with the fields of historical archaeology, architectural theory, and cultural anthropology, this session explores vernacular evaluations from various complex societies throughout the Pre-Columbian Americas. A focus on the vernacular in Pre-Columbian America is a productive way of thinking about how the ordinary interfaces with and also defies ideas of monumental time, the state, environmental parameters, large-scale religious movements, and changing community formations.
[112] Symposium · DINÁMICAS DE INTERACCIÓN EN PUEBLA-TLAXCALA
El objetivo de este simposio es discutir las distintas dinámicas de interacción a nivel local y regional en poblaciones prehispánicas de la región de Puebla y Tlaxcala a través de los materiales arqueológicos.
Durante la época prehispánica, el altiplano central de México se caracterizó por el desarrollo de importantes asentamientos humanos que mantuvieron distintos grados de interacción social y comercial. Aunque estas relaciones han sido abordadas anteriormente, en particular aquellas con regiones distantes o entre centros regionales de gran influencia pan-regional como Cholula y Cacaxtla, es claro que el flujo de bienes, ideas, y conceptos en relación con las fuerzas que lo producen en su lugar de origen han sido relativamente poco exploradas. En este simposio consideramos esencial discutir cómo se dieron las relaciones entre las distintas regiones para así lograr un mejor entendimiento de las dinámicas de interacción a nivel social, político, económico e ideológico a diferentes niveles dentro de las poblaciones de esta región clave de Mesoamérica.

[113] Symposium · ANIMALS IN ANCIENT NEW WORLD ECONOMY AND EXCHANGE
In comparison to other artifact classes (e.g., lithics and ceramics), the integration of animals and animal products into ancient New World economic and exchange networks is under-studied. Moreover, recent research shows that animal transport, management and exchange in the Americas may have been more common in the past than previously thought. This session therefore seeks to bring together researchers exploring the complex social and economic structures that were in place for the acquisition, husbandry, distribution, exchange, and movement of animals and animal products. More traditional zooarchaeological approaches will be presented alongside, and in conjunction with, innovative chemical and genetic analyses. This session will include presentations from a broad range of New World geographic and temporal contexts to generate discussion among researchers working in diverse cultural and geographic settings.

[114] Symposium · GEOARCHAEOLOGY'S CONTRIBUTION TO UNDERSTANDING THE PREHISTORY OF THE AMERICAS BEFORE CLOVIS (SPONSORED BY GEOARCHAEOLOGY INTEREST GROUP)
It is no exaggeration that geoarchaeologists have provided crucial data to understand the peopling of the Americas. Early 20th-century geoscientists had a direct hand in establishing a Pleistocene human occupation in North America when knowledge of Clovis, Folsom, and other Paleoindian traditions was still in its infancy. Interdisciplinary collaboration continued through the decades, and by the 1960s, geoarchaeologists were taking a lead role in making sense of hundreds of sites that were reportedly of Clovis age and older. Since then, an earlier-than-Clovis human presence in the Americas has been accepted with fair certainty by most archaeologists, but skeptics remain, and fundamental questions about dating, context, and site formation still exist. This session is devoted to the important contributions made by geoarchaeologists over the last few decades in unraveling the human presence in the Americas before Clovis. The group of papers offers a fresh look at how geoarchaeology has helped shape the history of arguably one of the most controversial topics in New World prehistory.

It has been 25 years since Grete Lillehammer wrote her seminal article, “A Child Is Born.” Since then, there has been much important research into the identification of artifacts produced by children in the archaeological record. While artifacts made by children have been identified from various materials, in this symposium we would like to focus papers on the presentation of current research involving manifestations of children’s artifacts, particularly those made by children from stone. This symposium will provide a venue for the presentation of papers addressing both theoretical and methodological perspectives involving child-produced artifacts. Papers addressing aspects of children’s artifacts along with gender, skill, craft learning, cognition, spatial analysis, socialization, community and cross-cultural research are encouraged.

Mesolithic prehistory has been one of the main topics of pre-historians. The reason is that it is a period of major economic, technological and social change, marking the end of the last hunter-gatherers of Western Europe. The case of the Portuguese Muge shellmiddens (Tagus valley), and specifically the case of Cabeco da Amoreira, is one of the most interesting regions to study this transitional phase from hunter-gatherers to food producers and the rise of social inequality. It is said that the richness of the estuarine and marine resources made possible the long-term settlement in Muge. New data and reanalyses of old data suggest the presence of incipient social complexity based on diet, interspatial site organization and inter- and intra-burial organization. This highly productive environment made possible the consolidation of an economic and social system of complex hunter-gatherers with a tendency for sedentism, possibly year-around camping, followed by the reuse of the shellmiddens by Neolithic populations. The present symposium will present the new data including technology, fauna (mammals, fish, birds, mollusks, crustaceans), charcoal, isotopes, spatial, geophysics, physical anthropology, and burial practices coming from the last 5 years of excavation and analyses.

[117] Symposium · DIRT AND SCIENCE IN THE AGE OF COMPLIANCE: RECONFIGURING GEOARCHAEOLOGY FOR APPLIED CONTEXTS (SPONSORED BY GEOARCHAEOLOGICAL INTEREST GROUP)

Geoarchaeology has long been integral for effective Cultural Resource Management (CRM). However, converging trends to applied archaeology, sustainability, and limited excavation leads regulators to rethink strategies that optimize information yield. Currently, scientific approaches from remote sensing to deep testing demonstrate that systematic exploration of buried landscapes is both legitimate and cost-effective for understanding settlement geography and preservation. In the present CRM climate, the transition from “open” to “imposed” research universes forces planners, CRM archaeologists, and geoarchaeologists to expand their interpretive skills as exploratory windows constrict. CRM challenges all contributors to communicate results to a variety of audiences. Our collective end product is explaining the systematics of archaeology to a public that funds our efforts and to regulators that direct the message of heritage preservation. In this program we view geoarchaeology as an overarching research and management tool that incorporates its methods for understanding the past (geomorphology, stratigraphy, site formation sequences), with those of related fields (geophysics and paleoecology). CRM archaeologists and earth scientists help synthesize the picture of changing landscapes and settlement geography. The goal of this session is to promote the dialog between cultural resource managers and geoarchaeologists in the age of slimmed down research territories but expanding research tools.

[118] Symposium · MODES OF PRODUCTION AND ARCHAEOLOGY

It is an understatement to observe that historical materialism has had a profound influence on the social sciences. Fundamental to such perspectives is the concept of a “mode of production” that seeks to describe how sociopolitical organization and ideology articulate with economic relations. Originally, Slavic, Asiatic, Germanic, and feudal modes were defined in ethnic/romanticist terms and contrasted with the, then emerging, capitalist mode. However, as Eric Wolf notes, the utility of mode of production analysis: “does not lie in classification but in its capacity to underline the strategic relationships involved in the development of social labor by organized human pluralities” (Europe and the People without History, p. 76). Modes of production provide a comparative framework through which archaeologists can explore how labor was organized to transform nature into culturally defined resources. It also provides a powerful analytical tool for studying change and reproduction in existing economic systems, social structures and ideologies. Papers in this session use archaeological data to explore modes of production. We do not try to generate conceptual uniformity but instead seek to explore variability in the ways that people organize their social relations to generate wealth and mediate contradictions within their societies.

[119] Symposium · SEEING NATIVE PEOPLE IN THE MISSIONIZED AREAS OF WESTERN NORTH AMERICA

Current archaeological research on Spanish missionization in western North America focuses largely on the varied ways that Native Americans negotiated the mission system. Yet theoretical and methodological challenges remain for the careful and non-dichotomous examination of indigenous experiences of missionization, including explorations of both continuity and change. The papers in this session speak broadly to the challenges of "seeing" native people in and around mission sites. Topics to be explored include: the interpretation of native use of "colonial" objects and space; the entanglement of
indigenous and colonial economies and foodways; the positionality and enactment of native identities in mission settings; understanding connections between missions and indigenous sites in the colonial hinterland; and recognizing challenges to the visibility of Native Americans in public and scholarly interpretations of mission history. The case studies span the Borderlands from Texas to California; an additional goal of the session is to stimulate conversation between archaeologists working at colonial sites across temporal and geographical divides.

[120] Symposium · PROCESSIONAL RITUALS IN THE AMERICAS
In the ancient Americas, ritual life was usually conducted in the open air, often as processions with movements guided by the design of the built environment as it was integrated into the natural landscape. This symposium will emphasize the identification, definition, and ritual use of space in action in Mesoamerica and South America, emphasizing how beliefs and behavior guided the movement of celebrants in ceremonial processions. Papers will bring together the nature of the belief system of culture-bearers at various sites with the interactive potential of the site’s architecture and art programs and the site's relationship to the landscape, exploring how the built environment drew attention to landscape features and how the senses were engaged to enhance processional experiences, considering the effects of seasonality, weather, temperature, and light.

[121] Symposium · PROVINCIAL USES OF INKA MATERIAL CULTURE
Inka-style objects made their way into the cultural repertoires of provincial people throughout the Andes. Although used under the purview of the state in official functions and rituals, these objects were also incorporated into cultural interactions in the local sphere. This began at the stage of manufacture, as most Inka-style goods were produced in the provinces by local craftspeople, and continued through the usage and final deposition of these objects. Although produced in the empire’s relatively standardized stylistic tradition, imperial-style artifacts had meanings and roles in cultural practice that were diverse and far from one-dimensional. In some cases, Inka-style goods were used to symbolize new identities and relationships within the imperial hierarchy. In others, local peoples found uses for imperial goods in political process of coalition building inside or between communities, or deployed them in ways that differed from or even contravened the original intentions of the imperial purveyors. In this symposium, we present papers that critically examine how provincial peoples made use of Inka material culture. Illuminating how Inka-style goods were mobilized for local social, political, and economic purposes demonstrates how incorporated communities were active recipients and manipulators of imperial material culture, and ultimately, co-creators of Inka rule.

[122] Symposium · THE EPHEMERAL, SENSED PAST: ARCHAEOLOGICAL APPROACHES TO SOUND AND HUMAN EXPERIENCE
The 2013 publication of "Making Senses of the Past: Toward a Sensory Archaeology" reveals renewed interest in an archaeology informed by experiential dynamics. Despite this, sound and human auditory perception remain underrepresented aspects of archaeological discussion. Material and methodological constraints are frequently cited as explanations for this absence, with arguments focused on the obstacles of accessing sound due to its ephemeral nature. Although such critiques pose practical concerns, myriad facets of the human past can be addressed through the examination of sonic evidence and its perceptual implications. Archaeoacoustic research examines ancient sound in terms of physical and experiential dynamics based on material evidence. Anthropological approaches to the auditory past leverage cross-disciplinary perspectives to investigate human interaction with others and the environment. Archaeo-musicological research applies iconographic interpretation, epigraphy, and ethnography to ancient musical instruments and performance practices. Explored from multiple angles, the study of ancient sound emphasizes the relational and temporal concerns inherent to all archaeological inquiry. Symposium participants are invited to consider the implications afforded by the temporal nature of sound, and its experiential entanglements. Research examples given here push the boundaries beyond methods for accessing past sound, to explore what sound can inform us about our past and present.

[123] Symposium · INVESTIGATIONS IN THE LAND OF CHOCOLATE AND HONEY: RECENT ARCHAEOLOGICAL RESEARCH ON CETUMAL BAY
Situated on the border between Corozal District, Belize and Quintana Roo, Mexico, Chetumal Bay has been a nexus for international economic exchange for more than two millennia. According to ethnohistoric documents, it was a vibrant market economy in the Late Postclassic, known then as the Land of
Chocolate and Honey. Today is no exception; the Belizean border is a booming free trade zone. Several decades of excavations at sites ringing the bay reveal a landscape of shifting settlement patterns controlled by alternating capitals, all subject to the whims of weather, piracy and politics. This session highlights recent work on both sides of the modern border, developing a clearer view of regional settlement and interaction on the shifting sands of Chetumal Bay.

[124] Symposium · ARCHAEOLOGIES OF LAND-USE: METHODOLOGICAL AND CONCEPTUAL ADVANCES
Archaeological investigations of humans’ relationships with their physical landscapes reveal novel insights into past social worlds. Beyond material studies of resource exploitation, economic relationships, and human impacts on the environment, studies of ancient land-use contribute to more complete understandings of the politics of place-making and social networking, the symbolic dimensions of spatial practice, the dynamics of labor and scheduling, and the role of human and non-human agents in trajectories of change. In this session, we contribute to this crucial field of archaeological inquiry by bringing together a series of papers surrounding the broad theme of land-use. The contributors to this session demonstrate the substantive implications of recent methodological advances in archaeometric, paleoecological, geoarchaeological, and GIS and remote sensing analyses, as well as develop theoretical perspectives that critically explore the significance of these approaches to a diverse array of research programs set across a variety of geographical and temporal settings.

[125] Symposium · NAVY ARCHAEOLOGY: RECENT RESEARCH AND CRITICAL PERSPECTIVES
Archaeology conducted by the U.S. Navy over the last several decades represents a broad array of environmental and cultural variation as well as application of method and theory. Navy archaeology has evolved from early permitting of academic research to established cultural resources management programs focused on Navy bases throughout the United States, in overseas territories and nations and on watercraft and aircraft wrecks in national and international waters. From Japan and Guam to southern California and the Chesapeake Bay, Navy archaeology is global in geographic scope. Archaeological and historic cultures range dramatically, to include Paleoindians and historic homesteaders of the desert, coastal prehistoric fishermen and foragers, World War II aircraft and Civil War shipwrecks, and Reconstruction era communities. Including discussants, this symposium will examine Navy archaeology from multiple perspectives. Highlights of recent research will illustrate the successes and challenges of current projects. Major achievements in long-term Navy archaeology programs, including scientific research, management strategies and research partnerships will be reviewed. Critical perspectives will be offered on the evolution and direction of Navy archaeology. Future directions for advancing and integrating archaeology into the military mission of warfare readiness will be explored.

[126] Symposium · THE EMBODIED POLITICS OF INEQUALITY AND PAIN: CASE STUDIES FROM BIOARCHAEOLOGY
A hallmark of modern bioarchaeology is its commitment to a holistic theoretical approach. The biocultural synthesis has indelibly shaped bioarchaeological research and has challenged scholars to reconsider the upstream causes of health disparities, and to situate trauma, violence, disease, mortality and morbidity data within broader social and political contexts. Social transformations that result in inequalities are reflected in both subtle and nuanced ways in human remains. Case studies draw on embodiment theory to clarify the politics and social processes that underlie pain and suffering for subgroups within societies. By integrating human skeletal remains, ecological data and contextual information regarding the social and political factors relevant to each case study, scholars in this session provide models for thinking about the ways that various political institutions become literally embodied in skeletal patterns of injury, disability, trauma and illness. These case studies advance discussions of how politically motivated inequality causes pain and suffering, and how this in turn can motivate various forms of resistance and agency or compliance and subordination.

[127] Symposium · STEPPING AWAY FROM GRAND NARRATIVES: QUOTIDIAN EVENTS IN THE ARCHAEOLOGY OF THE EASTERN MEDITERRANEAN
It has become a cliché in archaeology that our disciplinary strength lies in addressing the longue durée. True, archaeological data have unique temporal depth, but archaeologists often have access not to the longue durée, but the événement—the short-term event. This is true because human lives are short, and also because, to quote Hodder, "archaeological understanding of the long term is built up from traces of
the smallest and least significant of acts.” Archaeological contexts are residues of events of deposition and abandonment. Contexts for which the events of deposition are easiest to reconstruct are most desirable: destructions, total abandonments, short occupations, opportunistic reuse, etc. For archaeologists, the événement provides insight into the experience of ancient life. That moment tells us about the ordinary people who left their things behind, and this session will examine these people, rather than the grand political, social, or historical contexts they lived in. It is difficult to separate local studies from their larger contexts; our aim is not to decontextualize, but to personalize. We do not deny the role of deep historical structures in daily life, but rather explore how we can "see" these structures, and exceptions to them, through archaeologically visible événements.

[128] Symposium · BOUNDARIES, FRONTIERS, AND NETWORKS: SOCIOCULTURAL INTERACTION IN LOWLAND MAYA CIVILIZATION

Frontiers and boundaries have long interested archaeologists because they are essential to identifying past societies and describing the interactions that shaped their histories. Recent approaches in Maya archaeology have moved beyond traditional conceptions of “cores”, and “peripheries” to emphasize networks of interaction between groups and individuals within and across zones with differing practices and consequent contrasts in material culture. These studies often emphasized political and economic institutional arrangements, but the socio-cultural underpinnings of group identity and affiliation are equally important as these are the foundations of community, cross-cutting political hierarchy and economic class. It is easier to identify interaction between lowland Maya and members of distinct cultures and societies when they are separated by long distances, such as contact with Teotihuacan or Kaminaljuyu. It is more challenging to discern such dynamics when investigating borders of sub-regions within the Maya lowlands and close frontiers where the lowland Maya interacted with communities of distinct, but often related, societies. This symposium brings together researchers who have addressed these themes in the field, some for a generation and others more recently, and provides an opportunity to compare results and synthesize new directions in the study of borders and frontiers in ancient Maya civilization.

[129] General Session · BRAZIL AND AMAZONIA

[130] General Session · POLITICS, POWER, AND COSMOLOGY IN THE MESOAMERICAN LANDSCAPE

[134] Forum · "CRM-OLOGY": TOWARD A RESEARCH DESIGN FOR IMPROVING THE DOMINANT FORM OF ARCHAEOLOGICAL PRACTICE

Cultural resources management (also cultural heritage management) is generally thought of as archaeology’s commercial branch. Archaeology has held center stage and archaeologists have played leading roles in the broader enterprise of carrying forward significant and useful elements of sociocultural heritage. As CRM emerges from four decades of growth and diversification, this enterprise stands at a critical juncture. Will CRM practitioners, most of whom were trained in anthropology departments, continue to operate in the shadow of academic archaeology and allocate rewards primarily on the basis of contributions to our understandings of the ancient past and of relations among human groups, material objects, and geographic localities? Or, will CRM follow trails blazed by geologists, foresters, fisheries biologists, etc. by allocating rewards primarily on the basis of contributions to corporate business performance? If “management” means the identification and pursuit of desired futures, what is the desired future for CRM? Will CRM continue to operate using the Lipe’s “Conservation Model” or give itself over more completely to the “extractive-consumptive paradigm” that dominates in biophysical resource
management? How can archaeologists leverage our experience in CRM and expertise in research to create and mobilize knowledge that will enhance and expand the benefits of CRM?

[135] Forum · COLLABORATION 101: PRACTICAL TIPS AND CAUTIONARY TALES IN COMMUNITY-BASED ARCHAEOLOGY
(SPONSORED BY IPIG AND CNAR)
Many archaeologists today work in collaboration with communities as well as various agencies, institutions and the general public. Every new collaborative venture has its own unique political landscape informed by the concerns and agendas of these multiple stakeholders. But what can we generalize about the process of developing a collaborative archaeological project? What makes successful, meaningful and long-lasting relationships and what are some tips for those thinking about beginning a collaborative project? What are some difficulties that seem to commonly occur when working with communities and agencies and what are some of the ways that we can productively and efficiently address these difficulties? What are some situations that are unsolvable and when and how is it appropriate or necessary for research partners to take a step back or back out of a project entirely? What are some of the issues that students in particular should consider when wishing to engage with their own or other communities and begin a community-based or collaborative project for their thesis or dissertation? In this forum, we will explore how collaborations happen and what we can learn about the process of collaboration from the experience of our panelists.

[136] Forum · CHARACTERIZING TRIBAL CULTURAL LANDSCAPES FOR RESOURCE PRESERVATION AND PROTECTION
Understanding locations and types of significant archaeological and cultural resources is essential to their preservation and consideration during ocean and coastal planning processes. The goal of this project is to develop a proactive approach to working with Native American communities to identify such areas of tribal significance. Information from this effort will facilitate decision-making practices that consider the importance of these locales, giving tribal communities a stronger voice during regional planning. This project is a collaborative effort among the Bureau of Ocean Energy Management (BOEM), National Oceanic and Atmospheric Administration (NOAA), Tribal Facilitators, and the Tribal Historic Preservation Offices of the Confederated Tribes of Grand Ronde in Oregon, Yurok Tribe in California, and Makah Tribe in Washington. This project uses a holistic cultural landscape approach that integrates science with historical, archaeological and traditional knowledge. The resulting tool describes methodologies and best practices for tribes to identify and communicate areas of significance; case studies from the three tribes will demonstrate how to use this tool. This effort will provide transferable, transparent and cost-effective methods for tribes to document places and resources, past and present, significant to their communities and outside agencies, thus enhancing their capability for consultation.

[137] Poster Session · MAYA ARCHITECTURE AND SETTLEMENT PATTERNS IN BELIZE

[138] Poster Session · ANALYSES OF MAYA MATERIAL CULTURE FROM BELIZE

[139] Poster Session · THE CARIBBEAN AND CENTRAL AMERICA

[140] Poster Session · MESOAMERICAN ARCHAEOLOGY

[141] General Session · SOUTHWESTERN NORTH AMERICA

[142] Symposium · CURRENT RESEARCH FROM THE PIMU/CATALINA ISLAND ARCHAEOLOGY PROJECT
The Channel Islands off the coast of Southern California continue to fascinate and provide evidence of life for over 10,000 years. Within the southern Channel Islands, Catalina Island has received the least amount of attention despite over fifty years of professional excavation. The Pimu Catalina Island Archaeology Project is a collaborative effort between the Gabrielino/Tongva community, archaeologists,
and Catalina Island Conservancy to synthesize and further explore the cultural history of this island. This session focuses on the current findings and research by the Pimu Catalina Island Archaeology Project specifically highlighting the latest field and museum research at SCAI-39 (Two Harbors) and SCAI-564 (Toyon Bay). More broadly the project continues to bring together threads of data covering several centuries from early archaeologists, explorers, treasure hunters, and tourists.

[143] Symposium · MASCULINITIES AND VIOLENCE IN PRECOLONIAL SOCIETIES OF THE NEW WORLD
(SPONSORED BY COSWA)

Both the role of conflict and expressions of social identity have been the focus of long-standing debate within the study of ancient New World societies, although their intersections are rarely explored. Within the social sciences, connections between masculinities and violence are investigated to understand the ways in which dominance is utilized to prop up hegemonic masculinity, to explain unequal patterns of gendered violence, and to identify practices by which gender is performed. This session aims to explore the articulation of a broad set of behaviors understood as violent, or centered in conflict, with masculinities, in order to rethink our understanding of the ways in which the social contract of gender evolves. Decades of research on the importance of gendered behaviors and social identities in the ancient cultures of the New World has shown that femaleness and maleness existed as salient social categories throughout the region. These conceptualizations of social difference evolved and intersected with other forms of identity. Gendered expectations were circulated through craft production, political structures, ritual performances, daily life, etc. We will explore the hypothesis that masculinities were a form of social negotiation about difference and belonging that relied, in part, on the use of aggression.

[144] Symposium · CURRENT RESEARCH WITHIN THE CASAS GRANDES WORLD

While completing summer fieldwork in the Casas Grandes region, we realized that given the current research that has been recently completed and or is nearing completion, now would be an appropriate time to organize a symposium specifically focusing on Paquime and its neighbors. Whereas Charles Di Peso’s work with the Joint Casas Grandes Project (JCGP) continues to be a seminal work in the area, in depth archaeological descriptions and analysis were highly focused on the ceramic and architectural assemblages. These detailed analyses were primarily limited to Paquime, as well, to the neglect of the many other archaeological sites that we now recognize in the region. Additionally, the JCGP is now nearing 45 years of age. Since its publication a great deal of archaeological work has been completed, or is nearing completion, within the area, leading to a more comprehensive view of the Casas Grandes region. The aim of this symposium is to present these new perspectives and examine the implications these data have for our ongoing understandings of social development within the Casas Grandes world.

[145] Symposium · THICKLY SETTLED: INVESTIGATING “URBAN” ISSUES IN TOWN AND VILLAGE COMMUNITIES

More than 60 years ago, Childe (1950) argued that ancient urbanism transformed human societies, fueling a reorganization of social, economic, political and ritual elements in urban and urbanizing communities. He outlined ten key characteristics of ancient cities, including population aggregation and density, craft specialization, redistribution and surplus of staple and prestige goods, elites and non-elites, civic administration and recording systems, and monumental or civic architectural spaces. In the following six decades, archaeologists across the globe have discovered that many of these issues find expression in communities that cannot be defined as cities: how do we understand the nature of complexity in these towns and villages that “fail” the urban litmus test? This session’s participants explore how archaeologists understand and investigate densely populated communities in a variety of case studies spanning prehistory and history, all located outside of the classic ancient urbanism centers of Mesopotamia, Mesoamerica, and the Indus Valley. In particular, we discuss diverse theoretical models and scales of analysis in order to better understand the nature of social, economic, and political complexity in these not-quite-urban communities.

[146] General Session · CENTRAL AND SOUTHERN COAST OF PERU

[147] Symposium · RECENT WORK AT NIXTUN-CH’ICH’ AND TAYASAL, PETÉN, GUATEMALA

The Petén lakes region of Petén, Guatemala has been investigated for 20 years by Proyecto Maya
Colonial and its successors. This symposium considers recent (2009-2013) fieldwork and laboratory analyses of materials from the sites of Nixtun-Ch’ich’ and Tayasal, which rest on the western end of Lake Petén Itzá. The portion the lake was occupied by a group called the Itza during the Contact (A.D. 1525-1697 and Colonial (A.D. 1697-1821) periods. Excavations have uncovered the Colonial period mission of San Bernabé and a Late Postclassic through Contact period community on the Tayasal peninsula. A number of burials were recovered from beneath the floor of the mission church and are revealing much about burial practices, human health, and genetics during the Colonial period. Work at Nixtun-Ch’ich’ has recovered Colonial remains, a Late Postclassic community, and early Middle Preclassic constructions. Laboratory studies have investigated human mitochondrial DNA, fauna, historic and prehistoric ceramics, organic residues on ceramics, and lithics. Materials are considered relative to other sites in the Petén Lakes region as well as the larger Maya area.

**[148] Symposium · SEEKING SHELTER FROM THE SUN: RECENT CAVE AND ROCK SHELTER RESEARCH IN THE GREAT BASIN**

Archaeological research in the Great Basin has long featured caves and rock shelters - locations where excellent preservation often provides clues about prehistoric lifeways generally not found in open-air settings. Sites like Gatecliff Shelter, Danger Cave, Hogup Cave, Fort Rock Cave, Lovelock Cave, and others formed the foundation of our understanding of chronology, subsistence, and organic technology in the Desert West. This symposium highlights recent research efforts at other caves and rock shelters from across the Great Basin including the Paisley Caves, Bonneville Estates Rockshelter, the Promontory Caves, North Creek Shelter, Last Supper Cave, Rimrock Draw Rockshelter, and Little Steamboat Point Rockshelter. Ongoing work at those sites continues the tradition of cave and rock shelter research in the region and features both traditional and cutting-edge approaches to addressing longstanding questions about the past.

**[149] Symposium · CORRELATION IS NOT ENOUGH: BUILDING BETTER ARGUMENTS IN THE ARCHAEOLOGY OF HUMAN-ENVIRONMENT INTERACTIONS**

Although archaeology has a long history of interest in human impacts on environments and environmental influences on humans, construction of detailed arguments about causality in such interactions remains a persistent challenge. Limitations in chronological resolution of archaeological data and paleoenvironmental archives pose a methodological problem, while equifinality remains an interpretative challenge. Establishing clear contemporaneity and correlation, and then moving beyond correlation to causation, remains as much a theoretical task as a methodological one. The goal of articulating linkages between paleoenvironmental and cultural change remains a tantalizing one, as a means of better explicating cultural trajectories, a tool for examining human ecological footprints, and a strategy for untangling intertwined human and environmental histories in the long term. This session invites participants to explore theoretical and methodological approaches to human-environment interactions, addressing the key challenge of constructing arguments that can link the two in concrete and detailed ways. This may include ways of operationalizing theoretical frameworks, means of improving chronologies of human activity that are demonstrably linked to environmental conditions, exploration of paleoenvironmental proxies that can be concretely linked to human activity, or focus on particular times and places that lend themselves particularly well to exploring such issues.

**[150] Symposium · BEYOND THE HORIZONS: EXPLORING SOCIAL INTEGRATION DURING PERIODS OF POLITICAL DIVERSITY IN THE ANCIENT ANDES**

Horizons, or periods of broad regional integration, have traditionally received greater scholarly attention than the “intermediate” periods that precede or follow them. Chronological or theoretical frameworks that oscillate between horizontal integration and political disunity effectively define diverse political landscapes in oppositional terms—state vs. non-state, regional integration vs. regional fragmentation, or cultural florescence vs. cultural decadence—to the exclusion of more nuanced understandings of social, ideological and economic inter-connectedness during periods of political diversity. This session examines the core model of cultural development in the Andes, and asks: How well do chronological models of alternating horizontal integration accommodate the archaeological evidence of political diversity and inter-regional interaction during the Early Intermediate Period and Late Intermediate Period? What cultural continuities and innovations in subsistence, exchange, settlement organization, and mortuary practices are overlooked when intermediary polities are placed in a neo-evolutionary framework? This session explores the alternative modes of social integration, coordination and cooperation that arose in the absence of an integrative state apparatus or religious network in order to reevaluate characterizations of
social life as atomistic, decadent or fragmented during periods of regional political diversity.

Important events in 1974 make this year a milestone in the early development of cultural resource management (CRM) in the US. Since then, archaeological theory, method, technique, and interpretations have been influenced by work conducted as part of CRM. The 40th anniversary of the events of 1974 provides a stage upon which to review the historic developments, current challenges, and future opportunities of CRM in the US. Participants in the session, include leaders in the development and practice of CRM historically and during the four decades since 1974. Among our speakers are representatives of the generation of archaeologists that developed the administrative framework, methods, and techniques of this aspect of US archaeology. Also included are archaeologists who have conducted or directed thousands of CRM investigations and managed CRM programs at local, state, tribal, and national levels. Participants will describe their perspectives, interpretations, and opinions about the development of CRM, current issues, ongoing challenges, and future opportunities.

(SPONSORED BY SAA PUBLIC EDUCATION COMMITTEE)
Co-creation in public archaeology is a means to engage and empower citizens to become stakeholders of the archaeological record. In museum contexts Simon (2010:278) writes that the purpose of co-creative community projects is “to give voice and be responsive to the needs and interests of local community members; to provide a place for community engagement and dialogue; and to help participants develop skills that will support their own individual and community goals.” The papers in this session discuss a variety of recent archaeological projects that implement the co-creative model. The contributions demonstrate how co-creation moves beyond “hands-on” educational experiences or typical volunteer programs because participants are invited to play an active role in designing and constructing the final products to address their needs and interests. Co-creation aligns with current emphases on informal, life-long, and free-choice learning models that foster public engagement in the preservation of cultural heritage resources. The papers in this session also explore the benefits and challenges of using this method and provide examples of best practices for implementation. Finally, these papers speak to the impact of co-creation on the discipline and how the process increases the ability of archaeology to contribute to debates on contemporary issues.

[153] Symposium · RECENT RESEARCH IN NICARAGUA
Nicaragua has experienced an upsurge in archaeological research in recent years. This has included both international researchers from Canada, the Netherlands, Costa Rica, and the United States as well as the professionalization of Nicaraguan archaeologists through graduate training and collaboration with large projects. This symposium brings together scholars from diverse backgrounds to discuss recent research results and new interpretations. Discussants will then comment on longer-term trajectories and lead discussion of future directions.

[154] Symposium · 3D TOOLS FOR ARCHAEOLOGICAL RESEARCH IN THE ANCIENT AMERICAS
This symposium brings together researchers applying or developing 3D tools for research on ancient civilizations of the Americas. 3D technologies for data acquisition and visualization (e.g., photogrammetry, laser scanning, procedural modeling, and virtual reality) of archaeological artifacts, sites and landscapes are increasingly commonplace, and yet 3D data are often limited in their research uses. The symposium will address issues revolving around two central questions: How do 3D technologies help us to do archaeological research in the Ancient Americas? How can these technologies and tools help us to more efficiently answer traditional questions, and also formulate new questions, methods, and research strategies? Scholars working in the Americas on 3D applications for archaeology will share their research, demonstrate their tools and compare and discuss their results and needs in terms of 3D documentation, visualization and analysis.

[155] Symposium · FORGETTING AND REMEMBERING: THE ARCHAEOLOGY OF HISTORIC CEMETERIES.
Archaeologists have long used mortuary data to understand patterns of cultural behavior, spiritual beliefs,
social identity, and even public health and demographics. The manner by which communities inter their
dead reflect not just belief systems, but also circumstances and events affecting social life. Although most
Americans consider cemeteries to be consecrated spaces, cemeteries are lost or destroyed with alarming
frequency. From above-ground to below, this session examines not just what the physical remains of
cemeteries tell us about historical communities and their attitudes toward death, but also the varied social
forces that create archaeological sites from these cultural spaces. Papers will explore archaeological
approaches to the above-ground aspects of cemeteries, including issues stemming from vandalism, the
passage of time, and loss of historical memory. Increasingly, archaeologists also find themselves
exhuming mortuary remains, particularly those in unmarked cemeteries in advance of new land uses. The
below ground aspects of cemeteries and the multitude of data they offer will be addressed though
archaeological and bioarchaeological analyses of historic mortuary remains.

[156] Symposium · 2014 FRYXELL AWARD SYMPOSIUM: PAPERS IN HONOR OF MARVIN W.
ROWE (SPONSORED BY FRYXELL AWARD COMMITTEE)
For his contributions to the field of archaeological chemistry, Marvin W. Rowe is the recipient of the 2014
Fryxell Award for Interdisciplinary Research in archaeology. The Fryxell Award is presented in recognition
for interdisciplinary excellence of a scientist who need not be an archaeologist, but whose research has
contributed significantly to American archaeology. The award is made possible through the generosity of
the family of the late Roald Fryxell, a geologist whose career exemplified the crucial role of
multidisciplinary cooperation in archaeology. The 2014 Fryxell Award recognizes the area of physical
sciences. Rowe's laboratory developed a method called plasma-chemical extraction, which permits the
radiocarbon dating of rock paintings as well as the non-destructive dating of organic materials. For the
past 20 years, he has given his time and his dating method, often without cost, to rock art researchers
throughout the world. Rowe's plasma method is unquestionably the most successful way to establish a
numerical age for rock paintings. Due to his efforts, rock art is being integrated into the rest of the
archaeological record.

[157] Symposium · NOT JUST FOR SPECIALISTS: APPLYING GEOPHYSICS IN ARCHAEOLOGY
(SPONSORED BY INTERNATIONAL SOCIETY FOR ARCHAEOLOGICAL PROSPECTION)
Archaeological geophysics has moved from the domain of the specialist to a familiar and basic tool that
archaeologists routinely use to investigate sites. The papers in this session provide examples of how
gephysical surveys are currently being incorporated into archaeological projects. They illustrate the
range of geophysical methods that archaeologists are now using to investigate sites throughout the world.
They also show how geophysical methods are firmly integrated into standard archaeological practice at
all types of sites, from small to large, and from many different time periods, in many different
environmental and geological settings. This symposium is sponsored by the International Society for
Archaeological Prospection to foster international dialogue about geophysics and archaeology.

[158] Symposium · CLIMATE CHANGE AND ARCHAEOLOGY IN MESOAMERICA: A MIRROR FOR
THE ANTHROPOCENE (SPONSORED BY ANTHROPOCENE, ELSEVIER JOURNAL)
There are now books and many other publications about Mesoamerican climate changes but there is too
little research and understanding about the climatology and climatic trends of this region and how human-
iclimate interactions presage or push back the start of the Anthropocene. This session will integrate
climatology and regional archaeology along several lines with papers on the historical climatology of the
region derived from archives and a wide range of proxy reconstructions including microfossils,
geochemistry, speleothems, and tree rings. We will also consider the volcanic record and its influences
on climates and cultures in Mesoamerica and around the world. This session will host both new studies
and new syntheses from across Mesoamerica and studies of how climates and cultures correlate and
interact over time and how they push the boundaries of the Anthropocene.

[159] Symposium · THE CONVERGENCE OF HISTORY AND SPACE: HISTORICALLY-CHARGED
PLACES IN THE ARCHAEOLOGICAL RECORD OF NORTH AMERICA
Archaeologists have long been interested in the interaction of people and their surroundings as this
discursive relation has a dramatic effect on the character of human societies. In the last three decades,
archaeologists have increasingly focused on the complicated ways in which people and landscapes socially constitute one another. An important aspect of the relationship between people and landscape is the practice of “place-making” which consists of a diverse set of practices through which locales are set apart from the surrounding landscape. This session focuses on the ways in which history and space intersect in a particular manner to create places where human attention can linger and connections be formed. Events, both real and imagined, are often inscribed into the landscape through acts of deposition, excavation or other meaningful practices that are often visible within the archaeological record, creating “marked” space. These actions draw together different temporal moments and actors to create historically charged places which can become powerful social actors in their own right. This session asks archaeologists to reflect on the social power of historically charged places and the acts of place-making within their research, and how this reflection may offer deeper insights into the past.

[160] General Session · NORTHWESTERN NORTH AMERICA

[161] Symposium · NEW DEFINITIONS OF SOUTHEASTERN MESOAMERICA: INDIGENOUS INTERACTION, RESILIENCE AND CHANGE - PART 1
The traditional characterization of Southeastern Mesoamerica, an area made up of modern day western Honduras, El Salvador and parts of Guatemala, as the Southeast Maya periphery has been thoroughly critiqued by scholars over the last 20 years, who point out that the area was neither peripheral nor exclusively Maya. Recent research in this region has highlighted the diversity and dynamism of the indigenous groups that inhabited and continue to inhabit its borders. Alongside continuity in cultural, linguistic, social, and political processes, sweeping changes that have shaped the broad history of the region have also been identified. Research has also highlighted the interconnectedness of and communication between these groups, through networks of interaction, the migration of new peoples, shifts in political structure, and variation in art styles.

This multi-disciplinary session brings together researchers in order to highlight the diversity, dynamism, and ultimately resilience of the indigenous peoples of Southeastern Mesoamerica from the first Paleoindian populations until the present day. The goal of this session is to foster communication across time and space, in order to identify connections among the subregions within this area, and arrive at a more inclusive, updated, and ultimately more complex characterization of this area.

[162] Symposium · "FOR ONE PLEASURE, A HUNDRED PAINS": THE ROYAL HUNT IN THE ANCIENT WORLD
A Portuguese proverb cautions: “in war, hunting, and love, for one pleasure, a hundred pains.” The saying rang true in antiquity, when both war and love meshed with the significance, symbolism, ritual, display, and hierarchy of the hunt. Ancient hunting touches upon beliefs about the battle between people and nature; the triumph of civilization over savagery; male initiation rites; preparations for warfare, sexuality and dominance; heroes and myths; celebrations through text, image, and song; rituals and feasts; and morality, cosmology, and philosophy. This session explores these themes by focusing on the royal or noble hunt in its many manifestations: the open-air performances through which elite status was marked and maintained, armies trained, authority asserted, and the wild world tamed. Participants draw upon archaeological vestiges, artistic depictions, and literary descriptions to discuss and compare the meanings and motivations of royal or noble hunting in ancient societies.

[165] General Session · CULTURAL RESOURCE MANAGEMENT

[166] General Session · THE PALEOINDIAN PERIOD IN WESTERN NORTH AMERICA

[167] General Session · LATE CLASSIC AND POSTCLASSIC MAYA
[168] Symposium · UNEARTHING NEW SPAIN: HISTORICAL ARCHAEOLOGY IN THE SOUTHWEST
A product of the coming-together of indigenous, Spanish, and American peoples over the past several centuries, the American Southwest offers unique research opportunities for historical archaeologists. These papers illuminate topics and debates of interest to historical archaeologists, anthropologists, and related disciplines throughout the country such as public outreach, gender, commodity flows, and westward expansion. The geographic range covered, from Arkansas to New Mexico, Texas, and Nevada, shows the historically situated nature of the concept of the Southwest, and emphasizes links between the region’s margins and heartland.

[173] Poster Session · ALASKA AND THE NORTHWEST COAST

[174] Poster Session · MAPPING RELATIONSHIPS
Archaeologists look to landscapes as a means to analyze the past. These types of analyses include road functionalism and symbolism, hominin site spatial relationships, mortuary symbolism, living space arrangements, and societal spatial relationships, among others. Mapping these relationships, with technology for spatial analysis, can provide a means to better analyze and display these relationships. The group effort in this poster session of visually displaying data through various mapping techniques demonstrates the usefulness of this approach. For example, while fossil discoveries are limited, utilizing geographical information systems (GIS) can help in creating maps highlighting potential fossil sites based on known shared attributes, thus allowing one to better predict where to find fossils. Or, where the examination of function and meaning of roadways is largely theoretical, mapping them allows us to better examine their spatial relationships to nearby sites as well as other pathways. Finally, combining preliminary results from survey work with older corpus data are expected to show more accurate pictures of how site utilization and distribution change over time.

[175] Poster Session · STUDENT CONTRIBUTIONS TO PLATEAU ARCHAEOLOGY IN NORTHWESTERN NORTH AMERICA
Students provide a large body of research in archaeology, at both undergraduate and graduate level, working to further their archaeological understanding, both theoretical and methodological. New minds and fresh insights give us an opportunity to view archaeology from their perspective and gain insight into the future of the discipline. This poster session is organized to give students an opportunity to present their work to a broader audience, gain professional experience, and discover their place within the discipline by providing a student-only session with a focus on the Northwest interior plateau.

[176] General Session · HISTORICAL ARCHAEOLOGY IN WESTERN NORTH AMERICA

[179] General Session · MESOAMERICAN FIGURINES
[180] General Session · OLD WORLD CERAMICS

[181] General Session · SPACE, PLACE, AND ARCHITECTURE IN THE MEDITERRANEAN BRONZE AGE

[182] Symposium · WAR WITHOUT BATTLEFIELDS: A COMPARATIVE EXAMINATION OF WARFARE IN NORTH AMERICA
In archaeological settings, indirect indicators of conflict are often used to demonstrate that warfare occurred. The papers in this session will focus on the question of why some groups in North America devoted a significant investment in defensive construction and posturing without comparable evidence of inter-social violence. Much of the archaeology of warfare relies on indirect indicators such as settlement locations and warfare-related imagery. Therefore, it is essential to examine the relationship between proposed conflict and evidence of violence. Presenters will provide insights from context where some form of warfare likely occurred, but direct evidence of violence does not exist.

[183] General Session · ARCHAEOLOGY AND ETHNOHISTORY

[184] Forum · GENDER DISPARITIES IN RESEARCH GRANT SUBMISSIONS
(SPONSORED BY COMMITTEE ON THE STATUS OF WOMEN IN ARCHAEOLOGY)
According to program officers at the National Science Foundation (NSF) Archaeology Program and the Wenner-Gren Foundation for Anthropological Research, the number of grant proposals submitted by "senior" (i.e., post-Ph.D.) women lags behind the number submitted by men. These program officers also noted that dissertation improvement grant submissions are roughly equal between men and women, and that once they apply, "senior" women are funded at the same rates as "senior" men. To further understand why senior women are not applying at equal rates as men the Society for American Archaeology created the Task Force on Gender and Rates of Research Grant Submissions in spring of 2013. This forum has been organized to provide a venue for informal discussion of why women are not submitting proposals at rates equal to men as principal investigators to the NSF and Wenner-Gren. The discussants, all members of the SAA Task Force, will provide updates on their study and elicit from the audience possible factors in disparities in submission rates.

[185] Forum · STUDENT FUTURES PART 1: SURVIVING AND THRIVING AS A STUDENT
(SPONSORED BY STUDENT AFFAIRS COMMITTEE)
This is the first part of a forum designed to pair current undergraduate and graduate students with a panel of experts on academic advising. Student attendees will have the opportunity to address panelists in an "open mic" format with questions about course load, grant writing, curricula, service, publishing, and making the most of your academic life. The format is designed to be informal, informative, and fun!

[186] Symposium · NEW HOLOCENE RESEARCH IN THE TURKANA BASIN, KENYA: POPULATION CHANGE, SUBSISTENCE, AND CEREMONY
Holocene archaeological research in the Turkana Basin has long focused on the transition to food production: namely the appearance of cattle and sheep/goats ca. 4500 cal B.P. in an area previously occupied by hunter/gatherer/fisher communities. Current research is clarifying the social processes behind this transition (migration vs. diffusion) and relationships between early herding and the construction of extraordinary megalithic “pillar” sites around the lake. This session will highlight new results from excavations and ethnoarchaeological fieldwork in the region, bringing together various specialists to discuss the dynamics of population change, subsistence, monumentality, and material culture.

[187] Symposium · CULTURAL EVOLUTION OF NEOLITHIC EUROPE
The session will present recent research from a cultural evolution perspective on patterns of long-term social, cultural and economic change associated with the arrival of farming in Europe and its subsequent development. It will focus in particular on the relations between demographic patterns at both regional and sub-continental scales, and stability and change in these different domains, following recent work by Shennan and colleagues showing that population booms and busts followed the introduction of farming
in most regions of Europe. Papers will cover the following topics: theoretical background and introduction (Shennan); constructing a diachronic population surface (Timpson); long-term patterns in the agricultural system on the basis of archaeobotanical (Colledge) and faunal (Manning) evidence; modeling cultural descent and interaction in ceramics and ornaments (Crema) and lithic armatures (Edinborough); modeling selection and drift processes in ceramic decorative attributes (Kandler); changing scales of lithic production and metallurgical innovation (Kerig).

[188] General Session · HISTORICAL ARCHAEOLOGY IN LATIN AMERICA

[189] Symposium · RE-CONNECTING MUSEUM-BASED AND FIELD RESEARCH ON THE WEST MEXICAN SHAFT TOMB FIGURES
The finely made figures and dioramas of western Mexico have long attracted the interest of archaeologists, art historians, and museum curators, tempered by the sad fact that most of these objects were looted from shaft and chamber tombs and sold on the wider art market. Productive anthropological research on these unique artifacts faltered in the 1960s and 1970s as the visual analysis of decontextualized figures became increasingly distanced from field research. This symposium brings together recent archaeological fieldwork with collections based studies to re-connect these different fields. The session begins with recent archaeological research on discovery locations. A second set of papers will consider the use-contexts of the figures, and their significance for display or as offerings. The final focus of the session will be upon the enormous number of figures scattered across museum collections. Ethical debates exist over the use of donated museum collections, and must be weighed against the costs of ignoring literally thousands of figures. This symposium aims to expose current researchers to the productive lines of study currently taking place in the field and the museum, and to increase awareness of the potential that exists for integrative and collaborative research.

[190] Symposium · NEW DEFINITIONS OF SOUTHEASTERN MESOAMERICA: INDIGENOUS INTERACTION, RESILIENCE AND CHANGE - PART 2
The traditional characterization of Southeastern Mesoamerica, an area made up of modern day western Honduras, El Salvador and parts of Guatemala, as the Southeast Maya periphery has been thoroughly critiqued by scholars over the last 20 years, who point out that the area was neither peripheral nor exclusively Maya. Recent research in this region has highlighted the diversity and dynamism of the indigenous groups that inhabited and continue to inhabit its borders. Alongside continuity in cultural, linguistic, social, and political processes, sweeping changes that have shaped the broad history of the region have also been identified. Research has also highlighted the interconnectedness of and communication between these groups, through networks of interaction, the migration of new peoples, shifts in political structure, and variation in art styles.

This multi-disciplinary session brings together researchers in order to highlight the diversity, dynamism, and ultimately resilience of the indigenous peoples of Southeastern Mesoamerica from the first Paleoindian populations until the present day. The goal of this session is to foster communication across time and space, in order to identify connections among the subregions within this area, and arrive at a more inclusive, updated, and ultimately more complex characterization of this area.

[191] Symposium · IDENTITY ALONG THE FRONTIERS OF THE MAYA AREA: CULTURAL INTERACTIONS AND EXPRESSIONS FROM THE EARLY CLASSIC TO THE COLONIAL PERIOD
In this session participants will discuss the expression of identity in communities located along the periphery of the Maya Area, encompassing sites in Mexico, Honduras, Guatemala, and El Salvador. Identity is mutable and the artifacts or ecofacts used to express it, polysemic. While participants may perceive their identity as static, it is never stable and instead fluid and continually reconstructed and negotiated. Many archaeological sites reflect these multiple and sometimes conflicting identities within their confines, and over time their populations, or specific groups within the population, may embrace one identity more strongly than another. This is particularly clear in the case of those on the margins of the Maya cultural zone. The Maya area is bordered by distinctly different cultures, with some far more complex and powerful than others. These cultures were at times trading partners with the Maya and at other times competitors, conquerors, or the conquered. Tracing cultural reactions to these relationships is complicated. The most public forms of expression such as sculpture and architecture may reflect an identity belied by household contexts. Tracing changes in identity can provide important information concerning how cultures react to conquest, political changes, and natural disasters.
[192] Symposium · FISH AND FISHING IN THE PRE-COLUMBIAN AMERICAS

Recent archaeological and ethnohistoric studies have revealed that fish and fishing were highly important in organized societies of the ancient Americas, not only for sustenance but also for ritual significance. Fish and other aquatic resources such as shellfish and turtles have been identified as important sources of protein as well as sources of ritual implements including stingray spines, seashells, and carapaces; fish and fishing imagery also appears in murals, in codices, and on important monuments as elite ornament, as elements of ritual dress, and incorporated into pictographs and hieroglyphs. While important research on these topics has been conducted, the great potential for further investigation is yet to be fully exploited. This interdisciplinary symposium explores many different aspects of fish and fishing in pre-Columbian cultures, including fishing practices; fishing as an alternate foodway; fishing-related paraphernalia such as canoes, hooks, sinkers, floats, nets, and net weights; and the visual imagery of fish, fishing, and related paraphernalia and its import in civic and religious symbolism and ritual.

[193] Symposium · CURRENT RESEARCH IN EVOLUTIONARY ARCHAEOLOGY

Over the last decade the scope of evolutionary archaeology has expanded greatly and it now addresses a diverse range of questions in widely different time periods and places. The diversity of archaeological problems addressed by evolutionary archaeologists highlights the strength of this research program. This symposium brings together leading exponents of the evolutionary approach to archaeology to share their recent results and to identify potential areas of cross-pollination and collaboration.

[194] Symposium · TOO MUCH IS NOT ENOUGH: ABUNDANCE AS AN ECONOMIC PRINCIPLE IN ARCHAEOLOGICAL PERSPECTIVE

The papers in this session will evaluate a variety of global case studies in which individual and household engagements with material culture were conditioned by the quest for and attainment of abundance. Counterbalancing the prevailing emphasis on scarcity as the primary operative premise of ancient economies, the papers draw upon new economic theorizing to consider the social, political, and ideological implications of engagement with mass quantities of physical objects. Humans are certainly not the only species to preferentially gravitate towards plenitude as a criterion for landscape selection. Humans are distinct, however, in their propensity to create and augment conditions of abundance through the crafting of objects. People are particularly adept at taking natural resources such as clay, stone, and shell and adding labor value to produce items used for a variety of tasks such as trade, display, commemoration, and ritual deposition. In both simple and complex societies, archaeological data indicates the active solicitation of mass quantities that would have provided visual and tactile affirmations of self, identity, ritual cohesion, and economic well-being.

[195] Symposium · RECENT INVESTIGATIONS IN THE PUUC REGION OF YUCATÁN

The Puuc region is a triangular wedge of rough, hilly terrain that rises from the flat, limestone bed of Mexico’s Yucatán peninsula. Bordering the Serrita de Ticul to the north and the Bolonchen Hills to the south, organized exploration of this area first began in the mid-nineteenth century with the arrival of Stephens and Catherwood. Throughout the twentieth century archaeologists and architects continued to work in the region, documenting sites, surveying, and excavating. More recently, a push toward interdisciplinary research has further advanced our understanding not only of the archaeological history of the area, but its place within the greater sphere of Mesoamerican studies. This symposium brings together researchers working throughout the Puuc region to share new data on topics such as architecture, ceramics, hieroglyphic writing, the natural environment, and oral history. The intersection of these investigations continues to redefine research questions and increase our knowledge of the Puuc region and its periphery.

[196] Symposium · GEOPHYSICAL APPLICATIONS FOR CEMETERIES AND HUMAN BURIALS

Cemeteries and human burials are frequently the focus of archaeological inquiry in the United States. Common issues include the need to identify unmarked graves, confirm marked graves, and define boundaries, particularly in situations where records are incomplete or non-existent. Cemeteries also present unique research opportunities, as they are rich in demographic data. Because geophysical methods are non-invasive, they are particularly well suited for cemetery applications. This session is dedicated to bringing experienced practitioners together to discuss the use of geophysical survey methods, techniques, and instruments to address a range of research issues that are directly related to
cemeteries and human burials. It seeks to include case studies of historic and prehistoric cemeteries, instrument selection and methods, data processing, regional diversity, different environmental zones, and institutional, government, and tribal perspectives on management. The ultimate goal is to discuss the ways in which geophysics can be used to address specific problems that all archaeologists face with these resources.

[197] Symposium · EMERGENCE AND DEVELOPMENT OF COMPLEX SOCIETIES IN CENTRAL AMERICA: CONDITIONS FOR PRECOLUMBIAN SOCIAL CHANGE
Cuarenta años atrás en "The Archaeology of Lower Central America", editado por Frederick W. Lange y Doris Z. Stone, se presentó una perspectiva evolutiva sociocultural general de esa región a partir del poblamiento inicial, y se comparó con los desarrollos mesoamericanos y del noroeste colombiano, explorando la relevancia de la interacción entre esas áreas. En los últimos años investigaciones orientadas por perspectivas teóricas y metodológicas diferentes, han abordado desde múltiples dimensiones el cambio social conducive a sociedades complejas. Aquí buscamos hacer un balance de las investigaciones actuales que consideren las dimensiones culturales, políticas y económicas de esos procesos sociales en el Istmo Centroamericano, así como las posibles relaciones con regiones donde hubieron organizaciones sociopolítica analógicas, con el norte de América del Sur y el sur de Mesoamérica. Considerando que es necesario analizar la diversidad de formas de organización sociopolítica precolombina y sus trayectorias, los objetivos específicos son la exposición de resultados recientes de investigaciones afines al tema de la diversidad en el desarrollo de las sociedades complejas, junto con sus cronologías. Asimismo, intentamos la comparación de preguntas y escalas de análisis, sobre temas como configuración regional y local de asentamientos, organización política e ideológica, incluyendo la configuración de identidades.

[198] Symposium · LIFE AT THE MARGINS OF THE STATE: COMPARATIVE LANDSCAPES FROM THE OLD AND NEW WORLDS
This session brings together scholars whose research focuses on populations living in politically marginal landscapes. While the sociopolitical development of frontier or peripheral societies was no doubt closely interwoven with that of ancient state societies, their history, identity, and social organization was often forged independently of, or contrary to, the state. Societies “against” the state employed a number of strategies to maintain varying levels of autonomy, which are reflected in their ecological, linguistic, cultural, and ideological connections to the landscape. To examine these politically marginal landscapes, papers in this session will address the following questions: What is the nature of social complexity (or simplicity) in marginal landscapes? How did local histories support alternative pathways to power and modes of social organization? What was the relationship between landscape, local history, and identity? What strategies were employed to maintain autonomy? How did the physical landscape affect encounters between expansionary states and self-governed peoples? Methodologically, how can this be identified in the archaeological and historical record? By comparing approaches to these questions from diverse areas of the Old and New Worlds, papers in this session will contribute to a better understanding of self-governed peoples living at the margins of states.

[199] Symposium · LOWER PECOS CANYONLANDS ARCHAEOLOGY
The Lower Pecos Canyonlands of southwest Texas has a 13,000-year record of hunter-gatherers housed in dry rockshelters with extraordinarily well-preserved rock art and occupational deposits, as well as in open sites. The region is experiencing a renewed period of archaeological field research: survey, testing, mapping, excavation, rock art recording, and photogrammetry. This symposium highlights recent and ongoing field and analytical investigations in two research domains that are usually seen as separate worlds: rock art archaeology and dirt archaeology. Yet these two archaeological domains face common challenges and share methodologies, conceptual frameworks, and research rubrics to investigate, document, and interpret the archaeological record. After all, the same native groups that baked lechuguilla, trapped rats, discarded stone tools, and “deposited” coprolites also conducted rituals and painted elaborate murals, often in the same locales. This symposium highlights current archaeological research in the Lower Pecos Canyonlands.

[200] Symposium · RECENT ARCHAEOLOGICAL RESEARCH IN NORTH AND WEST MEXICO
Archaeological research in North and West Mexico has historically been overshadowed by discoveries and popular interest in adjacent regions, such as the U.S. Southwest and Central Mexico. For that
reason, North and West Mexico have predominantly received attention through research related to external colonization, migration, and large-scale economic systems. Despite the historically understudied nature of these areas and the societal roadblocks that have limited research in recent years, this session illustrates the diversity and depth of research that is currently being undertaken in these study areas. Paper topics range from hunter-gatherer lithic technology in Coahuila to the legitimization of authority through domestic ceramic production in Postclassic Michoacán. Other research themes in the session include material culture studies, new insights and methodological advances in the application of dating techniques (i.e., radiocarbon, thermoluminescence, dendrochronology and ceramic metatypologies), ethnoarchaeology, landscape and interaction studies from an array of projects in Sonora, Chihuahua, Durango, Zacatecas, Jalisco, and Aguascalientes.

[201] Symposium · THE FRISON INSTITUTE SYMPOSIUM: INTERNATIONAL PERSPECTIVES ON CLIMATE CHANGE AND ARCHAEOLOGY (SPONSORED BY THE FRISON INSTITUTE, UNIVERSITY OF WYOMING)

The Frison Institute Symposia aim to bring together international contributions on topics of broad interest to the discipline. The 2014 session covers climate change and archaeology. This session contains papers drawn from several world areas and a variety of time periods and examines the evidence for climate change and its impact on human subsistence, mobility, demography, society, and/or political organization. The papers examine the relationship between climate change and human society from a variety of temporal scales. In place of a discussant, there will be time for questions and discussion.

[202] Symposium · A GIFT FOR PASSION AND DETAIL: LINDA CORDELL, ARCHAEOLOGY, AND BEYOND

Linda Cordell influenced archaeologists and others through her enthusiasm and insight. Over her career, she shifted paradigms and approaches with her thoughtful analyses, was the intellectual matron of entire fields of study, directed a world-class museum, and was a role model for many. Beyond her scientific and methodological advances, Linda nurtured a generation of archaeologists through her kindness, support, energy, and encouragement. Her influence, however, extended beyond archaeology. She collaborated with artists, other scientists, and Native Americans on a wide variety of projects. This symposium honors her legacy by presenting some of the diverse projects she inspired.

[203] Symposium · INTEGRATING RECENT ADVANCES IN THE MORTUARY AND BIO-ARCHAEOLOGY OF THE MIDDLE HORIZON PERIOD (A.D.500-1000) IN THE SOUTH CENTRAL ANDES

The Middle Horizon (ca. A.D. 500-1000) witnessed the emergence, expansion and ultimate demise of the two states that dominated large areas of the south central Andes, Tiwanaku and Wari. Excavations and analyses of mortuary contexts in recent decades have made significant contributions to understanding Wari and Tiwanaku social identity and organization, diet and health, ritual and politics. Our goal is to take the next step forward, by moving beyond traditional approaches to burials and society and creating a multidisciplinary dialogue about death in the Middle Horizon. This symposium will not only bridge the cultural divide between the Tiwanaku and Wari states by incorporating the centers and peripheries of each polity. It will also include a diverse range of temporal, geographical, theoretical and methodological foci, including but not limited to studies of mortuary practices and bio-archaeology.

[204] Symposium · STONES IN MESOAMERICA'S GULF COAST: STUDYING SIGNIFICANCE THROUGH TECHNOLOGIES, FUNCTIONS, AND IDEOLOGIES

Cultural studies stressing materiality have gained increasing attention over the past decades as a result of the interdisciplinary recognition that individuals and objects are intimately intertwined in a complex network of relations. The material from which an object is made has the power to carry a host of intended and unintended consequences for the social history of that object. Studies of the Mesoamerican Gulf Coast have consistently brought attention to the remarkable and sometimes unique place of stone in the material production and ideologies of the region’s pre-Columbian peoples, from the ritual to the quotidian, the aesthetic to the pragmatic. The place of stone has often been elevated above that of other materials because it contains two antagonistic, yet complementary dimensions: the desire to transcend time and the desire to register it. This panel will address the uses, technologies, and ideologies of stone among the cultures of the Gulf Coast from the Preclassic to the Postclassic, combining perspectives from art history and archaeology to create a cross-disciplinary discourse about stone as a material affecting a wide range of social and cultural practices.
[205] Symposium · SMALL SITES, BIG IMPACTS: THE LOCAL LANDSCAPES OF COMPLEX SOCIETIES
This session brings together case studies that conceptualize complex societies as negotiated landscapes where regional dynamics of autonomous groups play significant roles. Complex societies are landscapes of human, animal, and environmental relationships that involve a multiplicity of actors within shifting cultural boundaries. Dependency of regional centers on small, hinterland sites may mean that small sites have greater autonomy than has been realized. A focus on small sites reminds us that these societal mosaics, of sites large and small, involve power strategies and resistance, negotiation, and compromise. At times, small sites may influence a polity's trajectory or may limit the consolidation of class-based power. Incorporating hinterlands into debates about emerging complexity encourages us to reconsider causal models of dominance by major centers and regional elites. The consideration of social and political dimensions of economic relationships is a common thread in the papers in this symposium, which demonstrate that external factors and elite strategies are not the only sources of complexity in past societies and polities. Complexity may also emerge from local actors and out of localized contexts: from small sites with big impacts.

[207] Poster Session · PEOPLE AND PLANTS

[208] Poster Session · ETHNOARCHAEOLOGY, REPLICATIVE STUDIES, AND SITE FORMATION PROCESSES

[209] Poster Session · HUMAN EVOLUTION

[210] Poster Session · MIDDLE AND LATE ARCHAIC PERIOD SUBSISTENCE AND SETTLEMENT IN THE WESTERN PHOENIX BASIN, ARIZONA: THE LUKE AIR FORCE BASE SOLAR-POWER-ARRAY ARCHAEOLOGICAL DATA RECOVERY PROJECT.
From 2010–2013, Statistical Research, Inc., (SRI) completed phased mitigation on Luke Air Force Base near Glendale, AZ, for the construction of a proposed 17-megawatt, 107-acre solar-power-array. Excavations encompassed 44 contiguous acres of a larger archaeological site, which contained over 3,000 buried and shallowly stratified features preserved in a lower-bajada environment. Project results include the most substantial evidence of Middle and Late Archaic land use in the Phoenix Basin and southern Arizona. Based on the archaeological and geoarchaeological analysis, the site functioned as a seasonal habitation or resource procurement, processing, and staging locale intermittently occupied between 7000 cal. B.C.–cal. A.D. 1200. Occupational intensity was greatest during the Middle and Late Archaic Periods, and especially between ca. 3300 and 2400 cal B.C. Evidence from these Archaic occupations reflects the activities of mobile foraging groups processing wild plant resources. Virtually no evidence of maize was recovered, suggesting the site occupants were not engaged in early agriculture, unlike contemporaneous groups along the middle Santa Cruz River near Tucson. This symposium presents the results of ongoing analysis that are increasing our understanding of the Middle and Late Archaic periods in southern Arizona and the greater U.S. Southwest.

[211] Symposium · QUARRIES AND EARLY MINES: BREAKING BOUNDARIES
(SPONSORED BY PREHISTORIC QUARRY AND EARLY MINES INTEREST GROUP)
This symposium examines quarries and early mines from a variety of perspectives beyond traditional discussions relative to extractive activities and geochemical analyses. Quarries and early mines occupy an important – if not unique - place in cultural landscapes. Pathways and trails associated with quarries, linking specialized sites, provide evidence of the organization of quarrying activities and the raw material transport. Geographic Information Systems (GIS) mapping provides new techniques for regional analysis at varying scales, leading to a deeper understanding of the ways in which communities inhabited a meaningful social landscape. We discuss how the specific qualities of raw material and place also played a role in the construction of memory and past ritual practice.
[212] Forum · STUDENT FUTURES PART 2: CAREER TRACKS FOR STUDENTS IN CRM, ACADEMIA, GOVERNMENT, MUSEUMS (AND MORE!) (SPONSORED BY STUDENT AFFAIRS COMMITTEE)

This is the second part of a forum designed to pair current undergraduate and graduate students with a panel of experts with distinguished careers in a myriad of archaeological contexts. Student attendees will have the opportunity to address panelists in an “open mic” format with questions about starting (and succeeding) in archaeological careers in museums, government service, academia, and CRM. The format is designed to be informal, informative and fun!

[213] Symposium · RE-THINKING THE ARCHAEOLOGY OF DIASPORA, DISPLACEMENT, AND POPULATION MOVEMENT

How do archaeologists view issues of population movement? Traditionally, archaeologists borrowed migration concepts from late 19th and early 20th-century geographers, and took diaspora concepts from historians. Diaspora and migration are commonly used terms, but what a “diaspora” or a “migration” is, as a theoretical construct and as a social and historical phenomenon, is not adequately discussed in archaeology. It is time to re-think classical diaspora and migration models. What are the material and social impacts on people and groups who are disrupted and displaced because of war, disaster, or economic development? How do issues of identity, continuity, and change intersect with diasporas, displacements, and migrations? How do archaeologists approach coalescence and dispersal? This symposium highlights different archaeological approaches and interpretations of displacement environments. The goal of this session is to transcend geographic boundaries and historic/prehistoric dichotomies and discuss diverse approaches to various phenomena of population movement and its associated material and social impacts.

[214] General Session · ARCHAEOLOGICAL THEORY

[215] General Session · HERITAGE MANAGEMENT

[216] General Session · SOUTHEASTERN NORTH AMERICA

[217] General Session · LITHIC ANALYSIS

[218] General Session · EARLY PREHISTORY IN NORTHEASTERN NORTH AMERICA

[219] General Session · NORTH COASTAL PERU

[220] General Session · SOUTHERN AND CENTRAL GREAT PLAINS

[221] General Session · HISTORIC ARCHAEOLOGY IN EASTERN NORTH AMERICA

[222] Symposium · STUDYING SOCIAL VARIATION AT THE COMMUNITY AND REGIONAL LEVELS FOR THE MIDDLE BRONZE AGE ON THE GREAT HUNGARIAN PLAIN

The transition from the Early to Middle Bronze Age (2000-1500 B.C.) on the Great Hungarian Plain was accompanied by significant population increases, the intensification of craft production and new forms of agricultural output. Masterfully executed spiral decorations and other symbols are found on axes, whip handles, and ceramics here and across large areas of Europe. These symbols are often considered to be the calling cards of a new elite social class. Yet research from different parts of the Great Hungarian Plain suggests that societies were organized in several different ways during this regional florescence. This session is largely dedicated to new investigations into the Middle Bronze Age community at the cemetery of Békés Jégvermi-kert in Eastern Hungary. The aim of research here by the Bronze Age Körös Off-Tell Archaeology (BAKOTA) project is to provide a richly contextualized case study, while improving methods for the recovery of social and biological information in cemeteries where cremation is the dominant practice. In this session we describe our methods, the local mortuary landscape, the demographic profile
and community customs practices here, and how different people in the cemetery fit into the regional patterns of trade, population movement, and conspicuous consumption.

[223] General Session · OLD WORLD PALEOLITHIC

[224] General Session · ABANDONMENT IN THE MAYA WORLD

[225] General Session · ARCHAEOLOGICAL PRACTICE

[226] Symposium · STATE FORMATION IN EARLY JAPAN
This session presents results of current research into the state formation process in Japan. The temporal coverage is from ca. third century B.C. to the eighth century A.D. During this time period, regional societies evolved from a simple chiefdom to complex chiefdom and eventually unified into a centralized state in the eighth century. A noteworthy aspect is the widespread distribution of keyhole-shaped tumuli or burial mounds all over the Japanese islands from the middle third to early seventh centuries, except Hokkaido and the Ryukyu Islands. Although most regions of Japan at that time seem to be unified under the standardized mortuary practices, strong regional differences existed. This session emphasizes the relatively autonomous role that regional societies played in the process of state formation.

[228] General Session · TEACHING ARCHAEOLOGY

[229] Forum · ERROR, SENSITIVITY ANALYSIS, AND UNCERTAINTY IN ARCHAEOLOGICAL COMPUTATIONAL MODELING
Computer modeling of past landscapes and human behavior have become common components of archaeological research. These models are expanding our ability to test inferences through desktop driven predictive modeling and exploration of individual and group-level decision making; however, there is a lack of post-processing analysis regarding the sensitivities of our models and in determining the location(s) of uncertainty. Such post hoc evaluation is a routine component of modeling in the earth and geosciences. The paucity of such sensitivity analyses in archaeology affects our model outcomes and application confidence, as model flexibility and reliability go unchecked. Without systematic development and incorporation of post-processing procedures in the archaeological sector, the validity of our models will continue to be viewed as subpar by members of the associated sciences from which we borrow methods and with whom we interact. These issues of analytic credibility and model robusticity are especially important to archaeologists working to forge interdisciplinary connections with researchers in related fields. This forum aims to facilitate open communication about the need for such sensitivity testing of our model analyses, as well as to collectively explore new directions for developing robust methods of sensitivity analysis for archaeological models of spatial behavior.

[235] General Session · EAST ASIA
[236] Symposium · LATE PLEISTOCENE LANDSCAPE STRATEGIES IN THE LEVANT: SOCIAL, TECHNOLOGICAL, AND ECONOMIC INNOVATIONS IN OPEN SPACES
During the late Pleistocene, the eastern Levant was characterized primarily by steppic and, to a lesser extent, open parkland ecologies. It also contained a number of paludal systems in the form of Pleistocene lakes, ponds, and marshes. In these respects, it differed considerably from the western Levant, where more closed Mediterranean oak forest was typical of areas north of the Negev and permanent bodies of fresh water, such as the Sea of Galilee, were present. Settlement systems and behavioral strategies in the more open landscapes of the eastern Levant likely encouraged social networks that may have been analogous to those of the contemporaneous open landscapes of Upper Paleolithic Europe during the advance, peak, and retreat of the Last Glacial Maximum. While many eastern Levantine Early and Middle Epipaleolithic sites are aerially small, they represent persistent places in the landscape. Additionally, there is evidence for larger aggregation locales. In this symposium, we examine Early and Middle Epipaleolithic hunter-gatherer strategies in the eastern Levant.

[237] Symposium · MASTER TEACHER, MASTER CRAFTSMAN, JACK OF ALL TRADES: A SESSION IN HONOR OF JAMES A. NEELY
The career of James Neely has spanned a broad range of field research from the Deh Luran Plain to Oaxaca and the American Southwest. He was also a world class archer before he began his university studies in archaeology. He has collaborated with Scotty MacNeish, Kent Flannery, Henry Wright, Frank Hole, and Bill Doolittle among others, and has mentored a generation or two of younger scholars through his teaching at the University of Texas at Austin and the W.S. Ranch Project. Neely is a pioneer of multi-disciplinary archaeology, especially in the areas of hydraulic and hydrological investigations such as at Hierve el Agua in Mitla, Oaxaca, at Purron Dam in Tehuacan, and at the Safford Valley of Arizona. This session is devoted to honoring his significant contributions to Americanist Archaeology and to his many students whose careers he nurtured.

[238] Symposium · ARQUITECTURA PREHISPÁNICA EN OAXACA; INVESTIGACIONES RECIENTES EN DIFERENTES ESTUDIOS DE CASO
Durante los últimos años el INAH ha realizado trabajos importantes de investigación y conservación en numerosos sitios arqueológicos del estado de Oaxaca. Esta mesa tiene por objetivo mostrar los últimos descubrimientos, analisis y discusiones que han generado estas importantes investigaciones en paralelo con los proyectos en curso del centro INAH Oaxaca.

Seventy years ago Congress passed the Flood Control Act of 1944. This act created the arguably most extensive public works program ever in the United States as it authorized the construction of dams, irrigation projects, hydroelectric and flood control devices throughout most of the United States. The Act also resulted in one of the most massive salvage archaeology projects yet in this country: the Smithsonian Institution's River Basin Surveys and the National Park Service's Interagency Archeological Salvage Program. These programs marked the onset of the modern era of cultural resource management and contributed to the passage of the major cultural resource legislation that still guides federal agencies and the federal preservation program. As such, the activities River Basin Surveys and the Interagency Archeological Salvage Program and the results of those activities continue to influence American archaeology today.

[240] Symposium · NEW DIRECTIONS IN FEMINIST ARCHAEOLOGY: PEDAGOGY AND PRACTICE (SPONSORED BY COMMITTEE ON THE STATUS OF WOMEN IN ARCHAEOLOGY)
This symposium discusses the ways feminist practices have become increasingly incorporated into archaeology. By addressing the ways archaeologists develop research designs, execute projects, enact classroom training, and frame teaching philosophies, this symposium focuses on the inclusion of new meanings and trajectories of feminisms to reach wider communities and underrepresented descendant groups, approach new research directions, and engage with diverse needs of students and stake-holders. Working in various temporal and geographical areas, the participants define and understand feminism differently, allowing a conversation around what can be considered feminist tenets, as well as illustrating...
various constraints on practices. Some participants discuss the difficulty in mediating theory versus practice in the classroom, strategies they have employed, and how current mentorship will affect the field in the future. Other participants explore how expectations, stigmas, and privilege affect how we define ourselves as archaeologists and how we interact with communities. As a whole, this symposium links where feminism in archaeology has been to where it is going and the many paths to get there.

[241] General Session · BIOARCHAEOLOGY

[242] Symposium · RECENT ARCHAEOLOGICAL RESEARCH IN OCEANIA
There are a myriad of archaeological research programs throughout the islands of the Pacific. Recent research in the region includes, but is not limited to, colonization studies, paleodietary isotopic analyses, chronometric hygiene, investigations of landscape utilization and modification, remote sensing, and elemental analysis of stone artifacts and sources. This session will present the diversity of themes and techniques in the archaeological investigation of Oceanic prehistory.

[243] Symposium · LEARNING & DOING: COMMUNITIES OF PRACTICE IN SCALAR PERSPECTIVE
Lave and Wenger's (1991) Situated Learning: Legitimate Peripheral Participation drew attention to the essential role of learning in daily activity and the material “arena” in which it occurs, one that involves relations among persons, activity and world. Their volume has inspired studies of apprenticeship, enskilment and embodied material practice, particularly in relation to craft production and formation of communities of practice. But less fully explored have been the scalar dimensions of these communities—through generations and across geographic distances—and their configuration in relation to variable dimensions of power. Contributors to this session explore how past learning communities relate to the socio-material units of varying scale that shape archaeological archives, asking how these were conditioned by power relations and differential knowledge transfer; how we conceptualize the situated apprentice in relation to both the longue durée and the broader socio-political economy in times of both ‘stability’ and ‘change’ and in relation to conservative and improvisational practice; and how we can surmount a focus on singular dimensions of learning (e.g., of a particular craft) to apprehend relationships of knowledge across domains and in relation to the role of non-human actants in the production and reproduction of social networks.

[244] Symposium · BARROW ISLAND ARCHAEOLOGY PROJECT (2013-2015), WESTERN AUSTRALIA: YEAR 1
The Barrow Island Archaeology Project (BIAP 2013-2015) is an Australian Research Council (ARC) funded project to study the exceptional record of deep-time Indigenous occupation on one of the largest islands off northwest Australia. The island and sites on it are optimally located to register first coastal occupations greater than 45,000 years ago; peoples' responses to major changes in sea level, climate and eventual isolation from critical resources on the mainland, with predicted abandonment 7,400 years ago. Important climate and ecological records are being reconstructed from the contents of caves and from surface archaeological sites reflecting ancient cultural landscapes. The labor history of Indigenous people and pearlimg is accessed through the study of historical sites. This session profiles results of the fieldwork in 2013, covering (1) the excavation of a stratified Pleistocene-early Holocene cave deposit, describing preliminary dates, faunal and lithic remains, climatic and environmental signatures, and hunter-gatherer mobility; (2) the survey of surface sites from and relationships to the lithic assemblage from the cave deposits; and (3) historical uses of the island resulting from survey and excavation of 19th century sites including Aboriginal glass, shell and stone tool technologies in their island and greater Western Australian context.

[245] Symposium · NEW PERSPECTIVES ON THE SOCIAL DYNAMICS AND ECONOMIC INTERACTIONS OF ANDEAN MARITIME COMMUNITIES
The study of maritime settlements of the Andean Pacific coast is of vital importance for understanding the emergence of social complexity. However, only recently have Andean researchers been extensively excavating these sites with a multidisciplinary perspective. Instead of focusing attention simply on subsistence patterns or material culture, recent research is using a multiscalar perspective in order to understand the role of these settlements. This symposium will evaluate, using a broad anthropological perspective, the importance of Andean maritime communities, from the Middle Preceramic (5000 B.C.) to
the Colonial Period (A.D. 1532), to the study of social dynamics and economic interactions.

[246] Symposium · HUMANS IN THEIR LANDSCAPES: PAPERS IN HONOR OF MICHAEL A. JOCHIM, PART 1
This is the first of two sessions that celebrate the career of Michael A. Jochim. Mike is a key figure in hunter-gatherer archaeology throughout the world. His research in hunter-gatherer land use and human ecology has led to the development of a major theme in archaeological thought. His innovative approaches to regional survey and site discovery, coupled with his long-term program of meticulous excavation, have transformed archaeological understanding of his region of study-southwestern Germany—and provide a model of how to design regional archaeology in general. Over four decades of work at the University of California, Santa Barbara, Mike's influence as a scholar and mentor has extended far beyond hunters and gatherers, and participants in this session underscore the breadth of his scholarship and impact. This session considers Mike's contributions to the field, focusing on complex hunter-gathers and on studies of hunter-gatherer and horticulturalist landscapes in north America, South America, and Europe. Mike's fundamental insight that human thought and action have to be understood in a regional context unifies this diversity and highlights his most significant contribution to our field.

[247] Symposium · SOUTHWESTERN BIOARCHAEOLOGY 2014: SYNTHESIS, REVISION, CURRENT TRENDS
This session brings together bioarchaeologists working in academic, CRM, and museum contexts to highlight ongoing work and update regional colleagues on the status of projects addressing significant topics in Southwestern bioarchaeology. These include the challenges and benefits of working on NAGPRA compliance projects, studies of biodistance and social and economic relationships across the Greater Southwest and at a smaller scale in the post-Chacoan Northern San Juan Basin, major revision and reinterpretation of Late Classic Hohokam demography, new studies of mortuary ritual and cultural variation among the Hohokam, Ancestral Puebloans and Basketmakers, synthetic studies of cancer and scurvy, and considerations of embodied identity and the role of violence in shaping the history of places and social memory. The breadth of topics addressed in this session and the range of contexts in which bioarchaeologists are working attest to the vibrancy of this small subfield and the significant contribution of well-crafted bioarchaeological studies to the understanding of life and death in the past.

[248] Symposium · TECHNIQUE AND INTERPRETATION IN THE ARCHAEOLOGY OF ROCK ART (SPONSORED BY ROCK ART INTEREST GROUP)
Wherever people have been, the cultural manifestation of rock art has the potential of being archaeologically identified and recorded. In the pursuit of enhanced interpretive insight and innovative instrumental technique, this Rock Art Interest Group sponsored symposium is intended to provide a context within which recent archaeologically informed rock art research can be shared. The geographic framework is global and there is no temporal restraint.

[249] Symposium · THE GOLD ANNIVERSARY OF OBSIDIAN SOURCING: 50 YEARS OF RESEARCH AROUND THE WORLD. PART I (SPONSORED BY INTERNATIONAL ASSOCIATION FOR OBSIDIAN STUDIES, AND SOCIETY FOR ARCHAEOLOGICAL SCIENCES)
It is now 50 years since the seminal publication by J.R. Cann and Colin Renfrew in the Proceedings of the Prehistoric Society (1964, vol. 30, pp. 111-133) on the characterization of obsidian in the Mediterranean, showing that elemental analysis could assign artifacts to specific geological sources. Since then, many studies have been done around the world, identifying and characterizing obsidian sources, and analyzing artifacts to address issues about trade and exchange. A wide range of scientific methods have been used successfully, not only for elemental analysis (e.g. XRF, INAA, PIXE, LA-ICP-MS, SEM, microprobe), but also isotope analysis, fission-track dating, and magnetic properties. More importantly, obsidian studies also are done on the technology of production, wear patterns and residues on artifacts representing their usage, their chronology using hydration dating, geospatial distribution patterns, and fall-off curves from the source area to peripheries. The papers in this session will include syntheses of what has been accomplished in certain areas, the latest on analytical methods, new results, and on the interpretation and integration of obsidian studies with the social, economic, and ritual aspects of ancient societies. The discussants will assess the past, present, and future of obsidian studies in archaeology.
[250] Symposium · WORLD ETHNOBIOLOGY: PAPERS IN HONOR OF DEBORAH M. PEARSALL  
(SPONSORED BY SOCIETY OF ETHNOBIOLOGY)
Tremendous advances in ethnobiological studies have been made over the last three decades. Through varied datasets and interpretive frameworks, ethnobiological investigations have produced novel insights into and greater understanding of a wide range of cultural dimensions, including dietary practices, subsistence strategies, social and political inequalities, gender, ritual and ideology, household and community spatial organization, among others. Deborah M. Pearsall has been a leading figure in the field of ethnobiology, particularly in the development and furthering of phytolith and starch-residue analyses. In addition, she has been at the forefront in promoting methodological rigor in paleoethnobotanical studies. While recognizing the importance of specialization in the maturation of ethnobiology, Pearsall has not been seduced by the allure of minutiae and steadfastly maintains a clear vision and perspective on big issues. In this session, colleagues with whom she has collaborated and former students will present papers honoring the contributions of Deborah M. Pearsall.

[251] Symposium · VISIONS OF OTHER WORLDS: IDEOLOGICAL AND RITUAL FUNCTIONS OF MISSISSIPPIAN SYMBOLS
A series of iconographic studies, based on multidisciplinary approaches, have yielded dynamic insights into the ideological visions of Mississippian societies and religion in the prehistoric southeastern United States. The papers presented in this symposium will cover topics such as the points of origin and movement of cults, the functions of symbols carried by specific cult objects within the larger stylistic geography of eastern North America, and the role of warfare within the broader category of cult manifestations. These presentations will also present new hypotheses about the functions of Mississippian symbols as instruments of social and religious communication.

[252] Symposium · RECENT TRENDS IN PLAZA INVESTIGATIONS IN THE MAYA LOWLANDS
It is well known that plazas were integral elements of ancient Maya site design. Plazas, however, are often viewed as empty spaces bounded by architecture. Although, scholars have interpreted plazas as locations for public gatherings and other activities, extensive plaza investigations have been limited in the Maya lowlands. In this session, we examine the various ways in which archaeologists recently have begun to investigate plazas and the significance of their findings. This includes broad scale exploration of single occupation periods for evidence of plaza activities such as marketplaces and ceremonial activities, as well as penetrating excavations to investigate earlier occupation, oftentimes dating to the Preclassic. Innovative methods, such as remote sensing, soil chemistry, and micro-artifact analysis, have proven useful in shedding light on plaza activities, as well as changes in function of plaza spaces through time. The papers in this session illustrate the important contributions that plaza investigations are making to a holistic understanding of how the ancient Maya created and utilized the open spaces within their sites.

[253] Symposium · NEW RESEARCHES AND TECHNIQUES ON LAPIDARY OBJECTS FROM MESOAMERICA: PROVENANCE, CIRCULATION AND MANUFACTURE
The detailed and systematic study of lapidary pieces has been increased in the last years with the development of new techniques of analysis, the revision of well-known assemblages, and the discovery of fabulous contexts with this kind of materials. The purpose of this symposium is to show, compare and discuss the different researches about diverse aspects of the lapidary objects made on different stones, related with provenance, mining complexes, organization of production, tools and manufacturing techniques, workshops, technological styles, exchange, distribution, and consumption of them in Mesoamerica. Beside these main topics, the presence of certain minerals, tools, and manufacturing techniques in different regions and cultures could link them by formal and informal trade networks and stimulated or developed regional and long-distance relationships. Also, some new discoveries will be presented in the symposium, with the register, analysis, and restoration of the pieces. Finally, with the new data and the current researches, it is possible to review, confirm or refuse, pioneer and classic lapidary exchange models and proposals of manufacturing techniques on this objects.

[254] Symposium · CITY, CRAFT, AND RESIDENCE IN MESOAMERICA: RESEARCH PAPERS PRESENTED IN HONOR OF DAN M. HEALAN
Dan Healan’s career in Mesoamerican archaeology represents a diverse contribution to the field both
thematically and geographically. Through his personal research, collaboration with colleagues, and mentoring of students, he has significantly impacted the studies of residential archaeology, quantitative analysis, craft production, and urbanism in areas as varied as West Mexico, Central Mexico, Oaxaca, the Gulf Coast, Northern Yucatan, and the Southeastern United States. An early advocate of statistics, multivariate quantitative analysis, and computer data entry, Healan’s approach to data analysis has left an indelible mark on generations of colleagues and students. His meticulous excavations in residential contexts at the Postclassic urban center of Tula, Hidalgo, Mexico, helped establish household archaeology as a major focus in Mesoamerican research. Moreover, Healan’s investigations of obsidian procurement, artifact production, and distribution at Tula and in Michoacan stand as seminal contributions to economic archaeology. This symposium celebrates Dan Healan’s achievements and influence that highlight recent research conducted by his students and close colleagues.

**[255] Symposium · EXPLORING VARIABILITY IN BIPOLAR TECHNOLOGY**

The differences and similarities between Homo sapiens, non-human primates, and their ancestors are key questions in anthropological research. Studies of the ubiquitous lithic material record have played an important, but debated role in such investigations. Variability in lithic assemblages and the limited use of these technologies in non-human primate societies results in problematic analogies. Bipolar technology, the use of hammers and anvils to produce tools and process materials, is found across the Stone Age and in non-human primate societies. This technology is highly variable and serves many purposes, depending on the goals of the action and its context. By focusing on this simple, but not simplistic, technology, researchers can build powerful analogies for broader behavioral and evolutionary relationships amongst human and non-human primates.

The session brings together a wide variety of researchers working on bipolar technology in human and non-human primate contexts. We will focus on the archaeological traces of bipolar technology, its use in a variety of contexts, as well as middle range research on the topic. The session will provide a platform for research groups usually separated by time period, region and species specialization to share perspectives and data on the most ubiquitous of lithic technologies.

**[256] Symposium · ARCHAEOLOGICAL APPROACHES TO THE PRODUCTION OF POWER IN THE COLONIAL ANDES**

Recently, colonial-period archaeologists in the Andean region have addressed a broad spectrum of indigenous positions relative to Hispanic colonialism—from active collaboration, selective accommodation/incorporation, passive resistance, and active, violent resistance. Spanish colonial interests were similarly divided among diverse state, religious and merchant institutions, producing locally structured and often fragmented landscapes of power. Archaeology is ideally suited for an inquiry into colonial power, not only through investigations into the material correlates of these behaviors, but also how materials themselves, including texts, artifacts, and spaces, provided avenues for the simultaneous production and destabilization of social power amidst competing colonial interests. In this session, we ask participants to address how their research examines the production of social power throughout colonial encounters, encouraging the exploration of transconquest or comparative perspectives with earlier Andean colonial programs. We seek papers that examine how the production of power was mutually constitutive and relational among Hispanic, indigenous, and mestizaje interests, linking analyses of colonial identity, gender, and class formation with anthropological inquiries into the ambiguities and ambivalence of social power.

**[257] General Session · NEAR EAST**

**[258] Symposium · BLOGGING ARCHAEOLOGY, AGAIN**

Blogging and social media have become indispensable tools for archaeologists in recent years. Academic and cultural resource management projects are utilizing blogging and social media for outreach and in classroom settings. The sharing of archaeology news and information by archaeologists and journals is a primary source of up to the minute information for many. A number of blogs are aimed at providing the public with information on either a single topic or a range of related topics. With all the benefits to blogging and the use of social media in archaeology there are still issues to overcome. The problem of relating site and project information to the public while maintaining anonymity of the parties involved and keeping site locations confidential is something that every archaeologist struggles with. In this session we will examine the ways archaeologists use social media and blogging and how problems related to the use
The Irish Great Famine is traditionally understood as a mid-19th century event that triggered depopulation through disease and massive immigration. Widely considered a watershed moment in Irish history, the repercussions lasted decades and affected millions of citizens. However, its victims are largely nameless, with limited documentary and material evidence available. While the economic situation that contributed to the Famine is often explored, the long-reaching social changes before and after created a context of rapid and dramatic social restructuring. The papers in this session explore the Famine as a much longer event than the traditional concept of the years of starvation. With archaeological data, the different kinds of experiences, adjustments, and alterations span decades and serve as one of the cornerstones of the development of modern Irish society. By examining the effects of the Famine at the scale of household, village and global city, this research suggests that the Famine is not only a physical event, but a mental one as well. The mentality of mass starvation continued without relief for thousands of Irish for decades. Rather than considering the events post-Famine as particularly derived consequences, the archaeology of the islands suggests the Famine was an ongoing experience lasting generations.

Blackwater Draw Locality 1, the Clovis site, played an important role in establishing the Pleistocene antiquity of the humans in the Americas, and was seminal in the development of the cultural and environmental frameworks we use to understand the prehistory of Western North America. Despite years of destructive gravel mining, intact deposits ranging in age from Pleistocene to recent remain preserved at the site and it continues to be central to active research being carried out by a number of institutions. The posters in this session bring together researchers from a variety of backgrounds, fields, and institutions to present the most current research on archaeology, paleoecology, and geomorphology at several localities at the Blackwater Draw site.
[272] General Session · MORTUARY PRACTICES IN EASTERN NORTH AMERICA

[273] Symposium · TRAFFICKING CULTURAL OBJECTS
The papers in this session focus on the illicit trade in cultural objects, which continues to harm cultural heritage worldwide. They build upon a strong base of scholarship that has already exposed the nature and scale of the damage caused by the trade to archaeological and other cultural sites, but broaden the scope of engagement by examining the economic and criminological contexts of the trade, which have in the past been somewhat overlooked. By so doing, it is hoped to develop an inter-disciplinary and comparative approach to the problem that will allow a more in-depth and nuanced understanding of the issues involved, and which will in turn feed into debates over appropriate forms of normative and legal regulation. The emphasis of the session is on market analysis, due to a belief that the trade will only be constrained by policies aimed at demand reduction.

[274] Forum · THE ENGAGED CLASSROOM: DEVELOPING ACTIVITIES FOR ARCHAEOLOGY COURSES
(SPONSORED BY SAA PUBLIC EDUCATION COMMITTEE)
Archaeology courses offer ample opportunity to engage students in creative learning. Our discipline is one of infinite curiosity and discovery, which translates well to hands-on and/or critical thinking exercises. However, designing and implementing appropriate activities can be a challenge, particularly for new instructors. It takes time to develop an activity, supplies may not be readily available, planned activities may not live up to expectations, or student interaction may be difficult to facilitate. This forum is designed to offer archaeology instructors the opportunity to discuss, brainstorm, and share classroom activities. Our goal is for attendees to leave with examples of activities that could be implemented in a variety of archaeology courses. Each discussant will present a successful activity, including sharing tips and techniques to replicate the activity. Forum attendees will then collaboratively outline activities to teach common archaeological concepts in an engaged manner, allowing participants to learn from the successes and challenges others have experienced.

[275] Symposium · TULA OF THE TOLTECS AND CENTRAL MEXICAN ARCHAEOLOGY: RESEARCH PAPERS PRESENTED IN HONOR OF DAN M. HEALAN
Dan Healan’s dissertation work at Tula marked the beginning of a long career with significant contributions to our understanding of residential organization at that emblematic Postclassic central Mexican urban center. While his career has expanded both geographically and temporally since then, his work there caused central Mexican archaeology to adjust focus and consider new variables in the cultural development of archaeological sites throughout central Mexico, not just at Tula. Helping to widen the scope of investigation in order to provide a more complete picture of the daily life of ancient Mesoamericans, Dan Healan has, through his work, led us to incorporate into our studies expanded data sets, including residential architecture, household economies, quantitative methods, and resource utilization to reconstruct the Mesoamerican past. This is the second of two sessions honoring the work of Dan Healan through essays by his students and close colleagues working in Tula and elsewhere in central Mexico, who have been greatly influenced by Healan’s work.

[276] Symposium · THE DESTINY OF THEIR MANIFESTS: MODELING SIXTEENTH-CENTURY ENTRADA ASSEMBLAGES IN NORTH AMERICA
Recent work by archaeologists, historians, and ethnohistorians, has begun to reveal a wealth of evidence concerning the widely variable, inter-ethnic relationships that characterized Native and European interactions throughout the sixteenth-century in North America. Although the breadth and depth of our data has expanded significantly, models of the complex, dynamic relationships between Native communities, Africans, and Europeans, continue to be underdeveloped. In particular, we have yet to create frameworks for evaluating, synthesizing, and comparing entrada assemblages and connecting the dotted path between object-oriented and site-focused analyses, and the wider patterns of world system dynamics. Contributions to this session focus on the integration of data from different sources and scales to characterize the nature of Spanish-led entradas, their activities, their consequences, and their inter-ethnic dynamics across sixteenth-century North America – from high deserts of Tierra Nueva to the coastal lowlands of La Florida. Our goals are to better understand what some of our earliest historic sites and materials represent, and to begin developing a framework for more broadly-based comparisons of entrada-related activities and materials.
Las Cuevas is a medium-sized Maya administrative/ceremonial center located on the east side of the Maya mountains only 14km from the mammoth site of Caracol. It was briefly investigated in 1958 during a brief seven-week field season by British archaeologist Adrian Digby and then Commissioner of the Belize Department of Archaeology A. H. Anderson, but no subsequent work was carried out. The site is of particular interest because of its somewhat unusual layout. Architectural features surround a dry sinkhole and a large cave system runs directly beneath the main plaza- hence our session title. The massive cave entrance sits at the base of the sinkhole directly below the eastern pyramid. The cave entrance is cathedral-like and architecturally modified with formal platforms and stairways that are stepped upward creating an amphitheatre-like space, which suggests that the cave was used for large and well-organized ceremonies. In 2010 the Las Cuevas Archaeological Reconnaissance renewed investigations at the site with the goal of understanding its significance in the changing Late Classic political environment, its relationship to other sites, and its role as a religious center. In this session we present work from the past three field seasons and offer preliminary results.

Not too long ago the term “Formative Period Urbanism” would have struck many Mesoamerican archaeologists as an oxymoron. Yet, research over the past 20 years has demonstrated that the Formative Period was not a mere prelude to the Classic Period (A.D. 300-900), but that in many regions it exceeded the Classic; not only were there true cities in the Formative period, but they were as large or larger than those of the Classic. The latter part of the Formative period saw the climax of a 1500-year-long trend of increasing complexity; cities were widespread throughout Mesoamerica, supported by systems of intensive agriculture, with elites who shared a pan-Mesoamerican tradition of high culture that included art, writing, religion, and engineering. Key issues addressed in this symposium include the following. What was the nature of Formative period urbanism in Mesoamerica? How do the processes of initial urbanization in Mesoamerica compare to those elsewhere in the world? How did Formative Period urbanism differ from that of later times in Mesoamerica? What role did the emergence of an elite intelligentsia play in the development of Formative Period urbanism?

The Calf Creek horizon, defined almost 20 years ago, covers most of the Southern Plains and is a significant temporal marker where it has been documented. This symposium presents recent research on this important period, dating to approximately 6000 years ago. Regional case studies define the geographic extent of this horizon and provide important information about subsistence, settlement mobility, and technological behavior. New findings document strategies for producing the elaborate toolkit that characterizes this period, including complex heat treatments to produce high quality toolstone as well as distinctive basal notching that defines diagnostic dart points associated with this horizon. High precision chronometric and environmental data contextualize some local Calf Creek manifestations. This period was important not only for hunter-gatherer adaptations, but also for the evolution from Bison antiquus to Bison bison. Calf Creek adaptations were part of well-established Archaic traditions, but are noteworthy for a series of highly elaborated behaviors that appear to have been focused on the successful hunting and exploitation of bison. The seemingly rapid spread of this horizon raises important questions about hunter-gatherer social organizations in the early-Middle Holocene.

This symposium brings together investigators sharing a significant common denominator: they find solutions to archaeological problems in the overlaps among multiple lines of evidence. Theoretical approaches are disparate, but each participant addresses a particular issue in New World societal development using an array of perspectives and ideas drawn from anthropology and allied disciplines, rather than interpreting the past solely through the lens of an autonomous archaeology. The authors of these papers recruit ideas and evidence from ethnography, oral tradition, historical linguistics, and biological population studies, along with archaeology sensu stricto, in order to build richer, more nuanced, and more reliable culture histories. Desacralizing the sacred bundle of four-field anthropology may have been premature.
[282] Symposium · LONESOME LANDSCAPES: THE ARCHAEOLOGY OF REMOTENESS AND ISOLATION
When one reflects on some of the most compelling archaeological discoveries, they all share a distinct aura of remoteness and isolation, either perceived or real. These terms are used by scholars and writers across and beyond our discipline, yet seldom is there a concerted effort to critically examine them. This session seeks to explore these concepts from a variety of perspectives and draw some useful generalizations. It is not our goal to agree upon rigid definitions, but to freely engage these concepts from the particular perspectives and data sets brought by each of the participants. The relative remoteness and isolation of a place can be the result of many factors and can have a variety of consequences for its inhabitants. Why do people choose to live in these places? Or do they avoid them? What vulnerabilities are unique or inherent to such contexts? How does this affect short-term planning and long-term adaptation? Achieving a better understanding of these tightly linked ideas will enhance our ability to comprehend the historical processes and past decisions that created the material record, for both evolutionary approaches, as well as perspectives more focused on social dynamics.

[283] Symposium · FORENSIC ARCHAEOLOGY: PAST CASES, CURRENT RESEARCH
As forensic archaeology continues to grow as a discipline and is utilized with increasing frequency by law enforcement officials, case studies are of great use to those engaged in forensic work. This session aims to highlight recent projects from those active in the field. In addition, this session also features research projects that will be of benefit to future forensic work and criminal justice. Those involved in research have the opportunity to address areas untouched by current practitioners. Research is essential to strengthening the theoretical foundations of forensic archaeology.

[284] Symposium · HUMANS ON THE LANDSCAPE: PAPERS IN HONOR OF MICHAEL JOCHIM, PART 2
This is the second of two sessions that celebrate the career of Michael A. Jochim. Mike is a key figure in hunter-gatherer archaeology throughout the world. His research in hunter-gatherer land use, evolution, and ecology has led to the development of a major theme in archaeological thought. His innovative approaches to regional survey and site discovery, coupled with his long-term program of meticulous excavation, have transformed archaeological understanding of his region of study-southwestern Germany —and provide a model of how to design regional archaeology in general. Over four decades of work at the University of California, Santa Barbara, Mike's influence as a scholar and mentor has extended far beyond hunters and gatherers. Participants in this session underscore the breadth of his scholarship and impact. We include papers on hunters and gatherers technology, land use, settlement and subsistence throughout the world, as well discussions of Mike Jochim’s contribution to archaeology as a field. We consider societies ranging from simple mobile groups to settled farmers and states. Mike's fundamental insight that human thought and action have to be understood in a regional context unifies this diversity and highlights his most significant contribution to our field.

[285] Symposium · RECENT ADVANCES IN THE ARCHAEOLOGY OF PACHACAMAC, PANQUILMA AND THE LURÍN VALLEY IN THE PERUVIAN CENTRAL COAST (SPONSORED BY INSTITUTO DE ESTUDIOS PERUANOS (IEP))
During the last two years, the Institute of Peruvian Studies (IEP) has been conducting research at the Late Intermediate Period site of Panquilma, located in the Lurin valley, 21 km from the religious center of Pachacamac. The main objective of this program is to investigate the role played by Pachacamac in the social organization of the Lurin valley during the Late Intermediate and Late Horizon Periods. Traditionally, research about this matter has been centered solely on the study of Pachacamac. We argue that in order to better understand this problem we need to focus also on the rural communities that, like Panquilma, developed under the influence of this important religious center.

Data collected from Panquilma's public, residential, and funerary sectors is revealing the different ways in which the religious ascendance of Pachacamac influenced the development of local political and economic processes. Papers presented in this session will discuss different aspects of Panquilma’s life and social identities, analyzing both the public and household levels, with a special emphasis in the relationship between these practices and the religious center of Pachacamac.

[286] Symposium · CURRENT ISSUES IN ZOOARCHAEOLOGICAL SAMPLING AND
METHODOLOGY  
(SPONSORED BY SAA ZOOARCHAEOLOGY INTEREST GROUP)
Zooarchaeologists have long recognized that field and analytic methods can significantly impact results and interpretation. Recent renewed calls for quality control and assurance in zooarchaeology reflect how methodological issues persist in the discipline. Sample representativeness, for instance, remains problematic, exacerbated by inadequate methodological reporting and inattention to the effect of varying sampling protocols. To this are added emerging methodological concerns, as newer analytic techniques, such as ancient DNA and stable isotope studies, become common investigative tools in zooarchaeology. Attention to these issues is critical, as they can impact analytic conclusions and broader archaeological interpretation, as well as hinder comparative approaches and cross-regional syntheses.

This symposium will explore current and emerging issues in zooarchaeological sampling, analytical approaches, and methodology. Topics are diverse, encompassing a range of issues from the trowel's edge to data dissemination. The session will provide a forum to identify and clarify methodological problems and advance their solution through awareness and discourse. Best practices will be considered, although standardized, one-size-fits-all approaches will not necessarily be advocated. The session will also include methodological concerns relating to isotope and aDNA applications in faunal analysis, integrating these into a holistic treatment of current issues in zooarchaeological methodology.

[287] Symposium · THE GOLD ANNIVERSARY OF OBSIDIAN SOURCING: 50 YEARS OF RESEARCH AROUND THE WORLD. PART II  
(SPONSORED BY INTERNATIONAL ASSOCIATION OF OBSIDIAN STUDIES (IAOS) AND SOCIETY FOR ARCHAEOLOGICAL SCIENCE (SAS))
It is now 50 years since the seminal publication by J.R. Cann and Colin Renfrew in the Proceedings of the Prehistoric Society (1964, vol. 30, pp. 111-133) on the characterization of obsidian in the Mediterranean, showing that elemental analysis could assign artifacts to specific geological sources. Since then, many studies have been done around the world, identifying and characterizing obsidian sources, and analyzing artifacts to address issues about trade and exchange. A wide range of scientific methods have been used successfully, not only for elemental analysis (e.g. XRF, INAA, PIXE, LA-ICP-MS, SEM, microprobe), but also isotope analysis, fission-track dating, and magnetic properties. More importantly, obsidian studies also are done on the technology of production, wear patterns and residues on artifacts representing their usage, their chronology using hydration dating, geospatial distribution patterns, and fall-off curves from the source area to peripheries. The papers in this session will include syntheses of what has been accomplished in certain areas, the latest on analytical methods, new results, and on the interpretation and integration of obsidian studies with the social, economic, and ritual aspects of ancient societies. The discussants will assess the past, present, and future of obsidian studies in archaeology.

[288] Symposium · FEAST, FAMINE, OR FIGHTING? MULTIPLE PATHWAYS TO SOCIAL COMPLEXITY
This session will explore the multiple pathways that may have given rise to social complexity from a variety of micro-historical, comparative, and theoretical frameworks. This interdisciplinary undertaking will employ a variety of perspectives and methodologies that encompass both materialistic and non-materialistic approaches. Factors to be considered include, but are not limited to, feasts (manipulation of surpluses), famines (shortfalls), fighting (intra- and inter-group conflict), environmental factors (climate change), demographic shifts (population increase/decrease) along with rituals and ceremonies (ideological propaganda). Findings from European, Asian, African, Oceanian, and North and South American locations will be put forth by an international cadre of archaeologists, cultural anthropologists, sociologists, and ethnohistorians.

[289] Symposium · COUPLED REGIONS, COUPLED SYSTEMS: DYNAMICS OF PREHISPANIC FARMING SOCIETIES IN THE NORTHERN SAN JUAN AND THE NORTHERN RIO GRANDE
The northern San Juan and the northern Rio Grande constituted the two major population centers of the Pueblo world during most of the prehispanic farming period. Here we address a wide range of questions concerning the social and environmental aspects of prehistoric Pueblo life in these two regions to produce a holistic view of their social and physical landscapes between A.D. 600 and 1760. Reconstructions of paleoproductivity, paleodemography, and violence across the northern Southwest; the nature of the community and community centers through time and space; models for migration; the development of political complexity; and the development of the economies in these two regions are
major foci of the presentations. We discuss the coupling between the socio-natural systems within each region, assess the degree to which these two regions were demographically coupled, and consider the role of these regions in the wider narrative of the prehistory of the American Southwest. This session is sponsored by the Village Ecodynamics Project, a multi-year, multi-institutional NSF-funded collaboration that explores the prehistory of the Pueblo Southwest using both the empirical archaeological record and computational modeling, and by GHEA, the Global Human Ecodynamics Alliance.

[290] Symposium · ADVANCING THEORY AND INTERPRETATION IN A 21ST CENTURY PACIFIC NORTHWEST ARCHAEOLOGY

The Pacific Northwest (PNW) region of North America is best known in anthropology for its complex fisher-forager societies. Ethnographers have had a profound impact on how archaeologists interpret the archaeological record in this region. However, the strength of the ethnographic record may also have played a critical role in limiting theoretical advances in the PNW as compared to other regions. Theoretical archaeology in the PNW region has generally emphasized explanations for the patterns of socio-economic and political organization described in the ethnographies. While this is important research, it has rarely led scholars to question the utility of the ethnographic record as the primary guide to the nature of more ancient societies known from archaeological research in the region. This symposium challenges scholars to move beyond uncritical reliance on ethnographic analogy in order to advance theory and interpretation in the Pacific Northwest region by exploring demography, socio-economy, political systems, gender, and colonial engagements. Drawing from multiple theoretical paradigms, presenters in the session address these themes while considering wider implications of their research for advancing Pacific Northwest archaeology in the 21st century.

[291] Symposium · BIOARCHAEOLOGICAL APPROACHES TO KINSHIP: BRIDGING BIOLOGY, SOCIAL RELATEDNESS, AND THEORY

Recent bioarchaeological approaches have placed emphasis upon individuals, communities, or populations as units of analysis, leaving mid-scale collective identities, including kinship, largely underexplored. A resurgence of ethnographic kinship studies has generated new, more flexible conceptions of “family”, while advances in multivariate statistical methods used in biodistance analyses and the increased resolution provided by molecular genetic approaches are contributing more reliable means of identifying biological kin in mortuary contexts. As a synthetic approach, bioarchaeology is well positioned to incorporate novel conceptions of kinship and use diverse datasets to reconstruct ancient kin relations. However, with few exceptions, bioarchaeology has yet to bridge the intellectual traditions of archaeology and biological anthropology in its treatment of “relatedness”. This session will emphasize bioarchaeological research employing complex conceptions of kinship to bridge biologically based and socially-constructed notions of relatedness. The goal is to move beyond the archaeological identification of biological kin to assessing social organization by exploring the interconnectivity of individual, kin-level, and population-level social identities. This research extends the multiscalar and deep-time perspectives on social organization that bioarchaeology strives to provide. Participants will discuss the challenges of applying these concepts to (bio)archaeological data and developing holistic approaches to kinship that incorporate both biological and social relatedness.

Leslie Shaw was one of those rare archaeologists able to conceptualize and work on a problem at different scales. In her research in Belize, New England, Wyoming, and on Easter Island, she looked at communities and their environments from multiple perspectives, believing that to understand the local, you must know the regional, and to understand the regional, you must know the local. While we all recognize that this approach is ideal for answering questions about the past, we tend to work exclusively from one perspective at a time, considering the others almost as afterthoughts. Yet the interplay of the interregional, regional, and local is as important to understanding behavior in the past as it is today. This is especially true when investigating topics such as Maya economic organization, a primary research focus of Shaw. In her work on resource use, site economies, and markets, she consistently employed a multiscalar approach, moving seamlessly between levels. This session’s papers reflect Shaw’s commitment to a holistic perspective and her particular research interests by contextualizing the economic life of prehispanic Maya communities at multiple scales. Examining how household, community, and region were linked enhances our understanding of all three and helps honor her legacy.

[293] Symposium · ARCHAEOLOGY BEYOND BORDERS: CURRENT INVESTIGATIONS BY
MEXICAN AND AMERICAN RESEARCHERS
The goal of this symposium is to present current archaeological investigations from throughout Mesoamerica and to provide an opportunity for both Mexican and American scholars to present their research in a common space. While transnational scholarship is increasing, this session aims to encourage further academic discourse between researchers that might not already be in communication. Collaborative projects between scholars in the country of research and international scholars create opportunities for investigations of previously excavated collections, training for local researchers in new methodological techniques, and financially investing in local economies by carrying out specialized analyses in the country of research. Thus, we hope that this symposium will serve to publicize current research endeavors by local and international scholars and initiate conversations that could lead to new perspectives and future collaborative research.

[294] Symposium · LAND USE AND SOCIAL HISTORY IN THE SOUTHERN CHUSKA VALLEY, NEW MEXICO.
The southern Chuska Valley lies at the interface between the Chuska Mountains and the San Juan Basin. The area is characterized by a rich and diverse archaeological record ranging from Archaic campsites to multi-storied masonry Great Houses. This symposium explores the long-term pattern of land use and the social history reflected in a series of recently excavated sites. Various topics are explored that aid in unraveling the dynamic and fluid nature that the past inhabitants coped with in an ever changing natural and social environment, with themes relating to household organization, early village formation and community development, as well as regional interaction and exchange.

[295] Symposium · RECENT APPLICATIONS AND INNOVATION IN ARCHAEOLOGICAL REMOTE SENSING
While remote sensing and GIS are now standard data modeling and research tools in archaeology, they are applied in widely varying ways. This session is dedicated to research employing remotely sensed data to address archaeological inquiries in diverse geographies, as well as facilitating discourse over the development of discipline-wide standards for technical data processing. The goal is to develop a discussion about the efficacy of certain techniques in disparate project types and geomorphological conditions through the presentation of real world case studies.

[296] Symposium · ARCHAEOLOGY SHOULD BE [ADJECTIVE/NOUN/PHRASE]: A COHORT’S PERSPECTIVE ON PARTICIPATION, PUBLICS, AND PARADIGMS
In common, session participants have had four-field anthropological training that attends to the applied and political dimensions of practitioners’ work. It is also no coincidence that participants are close in institutional cohort; our interactions have long made for productive, intellectual discussions. We now reflect on the present and future state of archaeology based on our subsequent experiences within and beyond the academy. To this end, and with the following queries in mind, participants insert in the title’s blank as they see fit. How do contemporary socio-politics impact research designs and practice/praxis? How might longstanding research questions, which have the ring of the commonsensical in need of interrogation, be reframed? What might be emergent areas of investigation—theoretical perspectives and methodological innovations—that require nurturing? What will archaeology’s relationship to anthropology be in light of ongoing disciplinary fragmentation, a fragmentation that we find particularly disquieting? How will the sub-field remain relevant given competing publics who interpret, consume, commodify the past? How can archaeologists participate in other humanistic and social scientific fields, to significantly impact discussions about materialism, complexity, power, and identity? Is it time for a paradigm shift? If so, what collective vision can we put forth to nudge this shift along?

[297] Poster Session · SOUTH AND EAST ASIA

[298] Poster Session · AUSTRALIA AND OCEANIA

[299] Poster Session · PALEOLITHIC, MESOLITHIC, AND NEOLITHIC EUROPE

[300] Poster Session · PREHISTORIC AND HISTORIC EUROPE
Bioarchaeologists are in a unique position to combine social theory, archaeological context, and biological data. This symposium highlights researchers who creatively employ scientific methodologies in a reflexive, humanistic manner that makes an effort to address the complexity of the human experience. When informed by social theory, technical methods utilizing human remains such as isotopic studies, ancient DNA, histology, back-scattered electrons--scanning electron microscopy, and computed tomography/3--D analysis are effectively used to explore the mortuary landscape. Derived from specialized methods, these data can inform intangible cultural ideas like identity, gender, status, and other anthropological inquiries at multiple scales of analysis. As techniques are implemented from other disciplines, particularly those in the chemical and biomedical fields, we must be cognizant that scientific methods have relevance to our field only if they are applied in association with social theory. Researchers in this symposium have united concepts of biology and culture to demonstrate the utility of scientific methods in anthropological studies.

The generation of practitioners who invented modern CRM archaeology in the 70s and 80s is retiring. A new generation of professionals now faces a variety of challenges and opportunities, some of which are as old as CRM itself and some of which are unprecedented. This symposium will highlight a variety of innovative approaches to training and mentoring young CRM archaeologists at universities, federal and state agencies, and consulting firms. It will also explore the both changing and familiar ground they'll cover as they take over the care and management of the past.

At some point between the 1st and 5th centuries A.D., workers built an 18-km-long causeway connecting Uc'i, located in the Northern Maya Lowlands, to a series of smaller settlements to the east, ending at Cansahcab. The causeway, which required hundreds of laborers to build, attests to an episode of micro-regional integration. Over the course of five field seasons, the Uc'i-Cansahcab Regional Integration Project has researched the process of integration, how it affected people living on and near the causeway, and how these people shaped and conditioned the process of integration. The project approaches these questions from multi-scalar and multidisciplinary perspectives, including regional survey, systematic mapping of sites at all levels of the settlement hierarchy, excavations of both households and monumental contexts, soil chemistry, hydrology, paleoecology, and remote sensing. The papers in this session explore both the integration represented by construction of the causeway as well as other processes, such as the decline of centralized power in the Late Classic period and the daily lives of Postclassic inhabitants.

The generation of practitioners who invented modern CRM archaeology in the 70s and 80s is retiring. A new generation of professionals now faces a variety of challenges and opportunities, some of which are as old as CRM itself and some of which are unprecedented. This symposium will highlight a variety of innovative approaches to training and mentoring young CRM archaeologists at universities, federal and state agencies, and consulting firms. It will also explore the both changing and familiar ground they'll cover as they take over the care and management of the past.

The papers in this session explore both the integration represented by construction of the causeway as well as other processes, such as the decline of centralized power in the Late Classic period and the daily lives of Postclassic inhabitants.
Historically, academic-based archaeological research in Mongolia has focused on the Altai, and western and northern parts of the country. The recent growth of mining-permit-driven CRM archaeology in the Gobi has brought to light the need for a synthetic approach that covers the country as a whole, both regionally and chronologically. The purpose of this forum is to promote dialog between researchers in an effort to “fit together the pieces” that exist now and are currently being discovered. An important aspect of this endeavor is to identify and incorporate data being generated in parts of the country about which little is known. In essence, this forum seeks to identify what we presently know, and what we need to know to complete the picture.

Should archaeologists even write fictional accounts about their subjects or research? Anthropologists know that cultural knowledge is traditionally passed on through stories, and that a good story entertains, transmits information, and often contains a moral, or cultural lesson. A small number of anthropologists and archaeologists have successfully used fiction to illuminate the lives of their subjects or their work. A much greater number of non-anthropologist writers have somewhat carelessly used the past as a setting for their fanciful writing. We explore the impact of both good and poor archaeological fiction upon the discipline and public. Participants will present short statements and read briefly from their work before engaging in a discussion of the inherent difficulties encountered in writing archaeological fiction. The second hour will be devoted to strategies for writing good, accurate, and engaging fiction. Additionally we will discuss current perils and pitfalls in publishing commercially, through the regional and academic press, and on-line. Audience participation will be encouraged.

Range Creek Canyon is a mid-elevation canyon located in the remote and rugged West Tavaputs Plateau of central Utah. The canyon encompasses 50,000 acres that exhibit high topographic relief, remaining a relatively inaccessible and remote location even today. The high density (ca. 450 sites) and virtually pristine nature of prehistoric Fremont archaeological sites offer a rare opportunity to researchers and have been hailed as a national treasure. In 2009 the Range Creek Field Station was established. The archaeological research in Range Creek is designed to accomplish three main goals. The first is to study and preserve the surface and subsurface archaeological remains present within the main canyon, as well as numerous side canyons within this drainage system. The second goal is to achieve a better understanding of the ecology of this arid environment through the reconstruction of paleoenvironmental changes through time. The third goal is to train students in archaeological survey, excavation, and analytical techniques. This poster session will detail the current and future direction of research in Range Creek Canyon. Poster topics include: Field stations, experimental corn farming, genetic variation in ancient maize, experiments in wild plant collection and use, excavation and micro-refuse analysis, strontium isotope studies, and paleoecological proxies.

Two principal phases of interdisciplinary investigations at Gault have documented long usage of the locality by hunters-gatherers. The first, 1999-2002, focused on Clovis and Late Paleoindian occupations
but also encountered hints of human presence prior to Clovis. The second, 2007-2013, focused on documenting the Older-than-Clovis cultural evidence and evaluating its contextual integrity and dating. In aggregate, substantial archaeological, geological, pedogenic, and chronometric data point to repeated habitations from well before Clovis, Clovis and Folsom, Late Paleoindian, and multiple Archaic intervals by people who followed a remarkably consistent life way of hunting, gathering and foraging in an environment well suited to these activities. This symposium highlights these investigations, the nature of the site, and the cultural and environmental data generated.

[319] General Session · MESOAMERICA

[320] General Session · ZOOARCHAEOLOGY

[321] General Session · POTTERY IN THE SOUTHWEST

[322] General Session · DIGITAL ARCHAEAOLOGY

[323] General Session · CULTURE CONTACT IN THE NEW WORLD

[324] General Session · GREAT BASIN ARCHAEAOLOGY

[325] Symposium · BACK FOR MORE: NEW INVESTIGATIONS AND PERSPECTIVES IN THE NORTH ATLANTIC

The coasts, islands, and near interior regions of the Atlantic Ocean north of the 45th parallel have been the setting for dynamic cultural change, invention, and elaboration. The archaeology of these processes has provided key data concerning human migration and interaction, long distance exchange, technological innovation, and the development of varying degrees of social complexity and organization. Because of the diversity of societies operating within a range of environmental and cultural contexts, the potential for research in the North Atlantic to address broader anthropological questions is undeniable. This session presents a subset of that research with an aim to highlight some of that potential. It will include the discussion of recent field and collections research examining new sites, as well as returning to some old ones with new perspectives and questions, utilizing a variety of theoretical viewpoints and innovative methodologies.

[327] General Session · MISSISSIPPIAN SOUTHEAST

[328] General Session · THE RECENT PAST

[329] Symposium · TRADE AND CERAMICS IN THE URUK EXPANSION: RECENT INSIGHTS FROM ARCHAEOEMETRIC ANALYSES

In the centuries after the formation of the earliest Mesopotamian cities and states (ca. 3700-3100 B.C.), the material culture of southern Mesopotamian cities and states was made and used at sites over 1000 km to the north and east. In recognizing this “Uruk expansion”, Guillermo Algaze proposed that one or more southern states had extended political control into peripheral areas in order to secure valued raw materials including timber, stone, and metals from the Zagros and Taurus Mountain regions. In the 25 years since his first presentation of the Uruk expansion, archaeologists have proposed numerous alternative models ranging from the implantation of colonies to exploit agricultural land to emigration of refugees from political struggles in the cities of Sumer. Yet there has been little available evidence to evaluate the role of trade and contacts in the Middle and Late Uruk period. This symposium brings together recent research based on archaeometric data. Trace-element analyses of Uruk-period pottery and seals from the Mesopotamian heartland and from far-flung sites in Syria and Iran are presented and evaluated in the context of current models of interaction in the Uruk world.
[330] Symposium · THE VALUE OF THINGS: COMMODITIES IN THE MAYA REGION FROM PREHISTORIC TO CONTEMPORARY
While archaeologists and other scholars have written about the roles of trade of commodities and elite goods from the prehistoric to contemporary Maya, this session is oriented to provide a new, dynamic temporal view of these roles. We examine the "value" of commodities – how the value of commodities went up or down, based on perceived need, rarity or over-production, quality – or the context. In addition, this session will examine prehistoric commodities on both the local and case study level and the macro-regional level. Presenters will examine the domestic labor side of commodities and view the laborers behind the commodity; i.e., the farmer, the henequero, the salt producer, etc., as well as the industrial side of commodities—the process of producing the commodity—the collection of raw materials, the tools of the trade. We also examine the role of innovation and imitation in the production of commodities—how do commodities reflect identity, ideology, ethnic markers, economic trends, and practical needs?

[331] Symposium · APPLIED ARCHAEOLOGY IN THE GLOBAL SOUTH: ACTION, ASSESSMENT, AND THE DEMOCRATIZATION OF PRACTICES IN ARCHAEOLOGY
This symposium seeks to motivate discourse and demonstrate approaches that reach beyond the oft used but rarely defined term collaboration. Case studies are offered from four continents and from various fields within archaeology to include historic archaeology, ethnoarchaeology, heritage studies, salvage archaeology, bioarchaeology, and community archaeology projects. Each participant offers new insights that may serve holistically to further render a more pertinent working definition for applied archaeology, an archaeology that adds value to well-being, employs feedback mechanisms, assesses social and environmental impacts, incorporates reflexivity, and marries policy, planning and project goals across the many diverse publics interested in the practices and outcomes of archaeological research.

[332] General Session · MEDITERRANEAN

[333] Symposium · INTEGRATION AND DISINTEGRATION: THE ROLE OF PUBLIC ARCHITECTURE IN THE PREHISPANIC AMERICAN SOUTHWEST
How did public architecture serve to mediate social integration and disintegration in the prehispanic Southwest? The papers in this session analyze various forms of public architecture found in the archaeological record—including great kivas, roads, D-shaped structures, shrines, and great houses—to shed light on how these constructs were socially mediated to create and maintain social structure, social identity, and intraregional community integration. Public architecture—or extradomestic structures and features constructed and used by more than one household or social group—are an important architectural element for creating and maintaining social relationships. The form of public architecture dictates the number of people who can participate in events, the kinds of activities that can be performed within a space, the seasonality of the activity, as well as the ideological and physical boundaries between sacred and domestic space. This symposium also addresses how public architecture was mediated during times of disintegration—periods when social order, social integration, and competing factions were present in the overarching environment. Can public architecture, and the activities that took place there, be used to determine episodes of dissolution? Presenters in this symposium are challenged with signifying the role of public architecture amidst integrative and disintegrative social environments.

[334] Symposium · RARE, INTRIGUING, AND POORLY UNDERSTOOD: INCISED STONES FROM THE WESTERN UNITED STATES
Stones with incised designs have been found consistently—if not frequently—at sites in the American West. The sites range in age from Clovis through at least the Fremont era, and perhaps later. Their geographic range appears to center upon, but is not limited to, the Great Basin. Design elements vary, as do the stone types used for the engravings and the shape and size of the stones. Some even resemble incised bone assemblages (themselves rare), including a Basketmaker collection of bone gaming pieces reported in this session as a comparative case.

Most archaeologists who have encountered assemblages of incised stones have found themselves at a loss to contextualize them, because although objects of this sort have been reported in the published literature, the reports are overwhelmingly descriptive. This session brings together case studies in an effort to assess the "state of the (incised stone) art" and ideally jump-start our collective ability to understand and interpret these compelling artifacts in the various contexts in which they occur in the
[335] Symposium · MULTI-SCALAR APPROACHES TO ARCHAEOLOGICAL INTERPRETATION

Archaeologists rely on a variety of techniques to analyze and reconstruct artifact, site, and landscape usage at many scales, ranging from microscopic surface wear to regional settlement studies. This symposium examines both traditional and emerging approaches to study significant information found on surfaces both large and small and how these approaches are used in archaeological interpretation at locations around the world. Emphasis is on what can be said about material culture, site and landscape usage based on the scale at which they are analyzed and how the scales of analysis can affect the interpretation of the behavior of past peoples.

[336] Symposium · LEARNING FROM DESTRUCTION: PATTERNS OF DECAY, PRODUCTION TECHNIQUES, AND EVIDENCE FOR USE OF FIBER ARTIFACTS  
(SPONSORED BY FIBER PERISHABLES INTEREST GROUP)

The fragility of fiber and textile artifacts limits the contexts in which they are preserved and complicates their archaeological analysis. Because of their roles in personal adornment, wealth accumulation, toolkits and rituals, these artifacts remain a rich source of information. Perishable materials are sensitive indicators of their own physical and chemical history; patterns of damage and decay may provide data on production, use, treatment and arrangement in the deposition context. Dye techniques, use wear, spatial arrangement, ritual destruction, imprints of other objects, libations, and exposure are a few examples of cultural practices that modify fiber artifacts and can contribute to their subsequent transformation. Careful field techniques improve recovery of both organic artifacts and spatial evidence for their presence, providing better context for those fragments that reach the laboratory. Advances in conservation practices and imaging techniques expand our research options while reducing loss in artifact analysis and storage. Wherever they are preserved, textiles provide an abundance of data that should be fully explored. This symposium will gather powerful examples of the analytic potential of differential preservation, to demonstrate how their very patterns of destruction turn fiber artifacts into a privileged source for information on ancient practices.

[337] Symposium · THE USE OF LIDAR IN MESOAMERICAN ARCHAEOLOGY: NEW APPROACHES TO SETTLEMENT AND RESEARCH

LiDAR (Light Detection And Ranging) has revitalized the field of settlement archaeology in tropical areas. Before the application of this laser-based technology, archaeology was operating within a largely unknown universe; researchers were never quite sure of how representative their archaeological samples were in terms of the larger landscape, thus complicating the interpretation of spatial relationships. The use of LiDAR effectively provides both horizontal and vertical control of vegetation-enshrouded environments that were extremely difficult to survey and enables researchers to more fully understand the human-nature interface of ancient societies in tropical regions of the world. This session brings together researchers that produce LiDAR with archaeological projects that have successfully utilized this technology for analyzing archaeological sites in Mesoamerica. The session emphasizes that the use of this important research tool does not obviate the need for on-the-ground confirmation of what is being interpreted; it also emphasizes how the collection of LiDAR point-clouds also enriches other academic fields, such as biology and, thus, represents the possibility of a truly conjunctive approach for archaeology.

[338] Symposium · INDIGENOUS PEOPLE AND FOREIGN THINGS: ARCHAEOLOGIES OF CONSUMPTION IN THE AMERICAS  
(SPONSORED BY AMERICAN ANTHROPOLOGY ASSOCIATION ARCHAEOLOGY DIVISION)

Long overdue in the archaeology of the Americas, this symposium focuses on indigenous consumption patterns, defined broadly as the acquisition and socialization of "foreign" things. Unified in their use of more nuanced approaches to human agency, cross-cultural interaction, and cultural reproduction, case studies in this session span a wide temporal and geographical breadth. Particular attention is paid to "consumer" choice, the redefinition of material goods in their new contexts, and the practical outcomes of consumption. Though certainly not limited to the study of once-European things recovered from Native American contexts, many case studies take this theme as their central focus. Building upon previous commentaries, these papers consider foreign things as much more than diagnostic temporal markers or straightforward indicators of Native American cultural loss. Other papers in the session explore deeper histories of indigenous consumption, providing new grounds for comparison and synthesis across long-
standing temporal divides in the discipline. Case studies target archaeological epistemologies while exemplifying the ways in which indigenous consumption patterns speak to issues of colonial entanglement, the sacred versus the secular, social dynamics, and the perpetuation and transformation of "traditions."

[339] Symposium · REASSESSING THE AZTATLÁN WORLD: CULTURAL DYNAMICS IN POSTCLASSIC NORTHWEST MESOAMERICA (A.D. 900-1450)

The resurgence of archaeological research in northwest Mesoamerica during the past decade has revitalized the debate over the nature of interaction and integration of Mesoamerican and Southwestern cultures. In antiquity, as in the present day, the far northwest region of Mexico formed an integral geographical landscape for regional and interregional trade and interactions, migrations, political actions and the exploits of culture heroes, warfare, religion and ritual practice, origin stories, and ancestor worship. Though under-researched and largely overlooked in discussions of Mesoamerican prehistory, it has become increasingly clear that the Azatlan culture of West Mexico was central to profound social transformations during the Postclassic period, both locally and in the macro-region. Situated in the modern states of Sinaloa, Nayarit, Jalisco, Durango, Zacatecas, and Michoacán, Azatlan socioeconomic networks intersected with broader interaction spheres stretching northward to northern Mexico and the American Southwest, eastward to the Huasteca along the Gulf Coast, and southward to the Mixtec region of Oaxaca and Puebla. In an effort to bring the Azatlan culture to the forefront of Mesoamerican studies, this session aims to illuminate recent Azatlan scholarship in order to formulate new conceptualizations on the significance of Postclassic West Mexico in the ancient Mesoamerican world.

Recontextualizing Social Identity in West Mexican Museum Collections

Rampant looting and faking has long stymied archaeological interpretations of the mortuary art from West Mexico. Recent developments in authentication allow us to ask new questions about the identities of the ancient people that occupied the area from approximately 1000 B.C.E. to 1000 C.E. Inspired by architectural evidence showing important differences and similarities across the region, I have looked for related variations in markers of social identity among mortuary art used in shaft tombs during the Late Formative to Early Classic period. These portrait-like hollow bodied ceramic figures are popular among collectors but have been of little use to researchers, as they have been stripped of their provenience through looting or marred by the presence of fakes. My research attempts to re-contextualize museum items without context by tying their symbolic markers of identity to those found on excavated pieces. By comparing excavated collections from different sub-regions of West Mexico to those authenticated pieces held in US museums, markers of social identity can be discussed in relation to geographic origins, thus giving us a fuller picture of who the artists and their audience were, how they represented themselves in art, and what roles they may have played in their society.

Reconstructing the Prehistoric Social Organization of Central Arizona: Electron Microprobe Results from “Phyllite Land”

The upland zone north of the Phoenix Basin of central Arizona contained various prehistoric villages and farmsteads mostly situated along intermittent drainages. This northern territory was rich in natural resources, but it was one with limited agricultural potential. If and how the upland settlements cooperated with one another and were organized into communities is poorly known. The upland zone is jokingly known to archaeologists as “Phyllite Land” because virtually all of the pottery made and used across that region was tempered with platy phyllite fragments, which bound well with the clay. The mineralogical uniformity of the temper has frustrated pottery provenance studies that rely on compositional variability. A program of chemical characterization of the clay fraction as well as of individual particles of phyllite temper with an electron microprobe is revealing pottery-exchange networks, which highlight patterned social connections among the upland residents and their ties to Hohokam irrigation-based communities to the south. A summary of methods and results from several previous and ongoing studies is presented.

Industry and Interaction: Craft Producers as Agents of Culture Change in Bronze Age Ayia Irini, Kea, Greece

Studies of exchange in the Bronze Age Aegean focus overwhelmingly on the interaction of states and elites. Changes in material culture often are ascribed to vague processes of “influence” or “emulation,” while the roles of non-elite, non-state agents in affecting change in local values and traditions are minimized, if not entirely overlooked. This paper offers an alternative approach. Using evidence for contact between local and non-local craft producers at the trade hub of Ayia Irini on the island of Kea, we suggest that some of the most significant changes in local ways of doing things at that site over the Middle and Late Bronze Age were conditioned by the interaction between potters, weavers, and other craftspeople. We argue that the adaptation of foreign technologies and objects into local practices by craft specialists not only affected the kinds of things being produced, but also had material consequences on the people who made and used them.

Rock Art at La Gruta Locality (Patagonia, Argentina)

The rock art of La Gruta locality (Santa Cruz province, Patagonia, Argentina) has been described and
interpreted, in brief and partial form, by different researchers since the 50s. Since 2006, the research team led by Dr. Nora Franco has begun to carry out systematic archaeological work in the area, focusing on two lagoons spaced approximately 1.2 km from each other, with volcanic and sandstone outcrops, where rock art has been identified. Excavations carried out within the locality show evidences of human presence since the Pleistocene-Holocene transition until the Late Holocene. In this poster we present the analysis of the rock art recorded in seven sites, including the images that were described by other researchers and those arising from our own surveys. Results from the comparative study show differences not only in the number of rock art sites and in the frequency of motifs, but also clear differences in the most frequent motif types (three digits versus negative hands) in the techniques (positive painting vs. negative painting) and in the superimpositions recorded on each lagoon. These differences have implications for the discussion about the existence of variable ways of marking the space with rock art motifs in a small area.

[71] Dabbling with Descartes: Contingent Knowledge and Evil Demons in Archaeology
Knowledge is always contingent to one degree or another depending on facts and the interpretation of facts. This is no less true of archaeology than any other discipline. At the same time, Descartes’ notion of evil demons suggests the possibility that there are untoward forces lurking in our cognitive processes that will mislead us in our perceptions about what constitutes a fact. The implications of being misled are obvious. This paper briefly explores the impact of evil demons on contingent knowledge in the conduct of archaeological research.

Acosta, Guillermo (Universidad Nacional Autonoma de Mexico)
[118] Early Agriculture Modes of Production in Mesoamerica: New Insights from Central and Southern Mexico
The revolution in food production is a recurring theme in archaeology. The relationship between changes in economic and social relations of production and changing social structure from hunter-gatherers to food producers were profound and defined all subsequent class societies. This paper evaluates the mode and tempo of these changes with published data and new research carried out in Chiapas, Oaxaca, Veracruz and the Basin of Mexico. Although the cultivation and domestication of plants began during the early Holocene (ca. 10,000 to 8,000 B.C.), it was only from 6,000 to 5,000 B.C. that a radical change in the modification of the environment occurred and the use of domesticated plants as staple food is first documented. These subsistence changes cannot be explained solely through an analysis of the mode of production and it is necessary to also consider the mode of reproduction of early agricultural communities.

Acuña, Mary Jane (Washington University in St. Louis)
[61] Bundles of Kingship and Wealth: The Iconography on Structure 5C-01-sub 4 at El Achiotal, a Frontier Site in Northwestern Petén
Located along the western frontier of the central karstic uplands and on the edge of the northwestern wetlands of Petén, Guatemala, El Achiotal was an important Late Preclassic center that participated in the regional political dynamics of the Maya lowlands. Although well within the lowland territory, I argue that El Achiotal was a frontier center operating on a westward communication network bridging the west with the core sites of the uplands through the wetland drainage system down to the San Pedro Mártir River. A small center, the iconography decorating the main temple locus is unique in style, but conceptually mainstream for the Late Preclassic period. The iconographic content of the murals makes reference to the practice of bundling. Bundling in reverence to the ancestors and divine kingship, as well as bundling of precious and jewels representative of ingots of value and wealth, and important symbols in the political economy and interregional interaction.

[220] Dating the Arrival of the Common Bean (Phaseolus vulgaris) in the North American Central Great Plains
The common bean (Phaseolus vulgaris) originated in Central and South America and dispersed
northward into North America during prehistory. Accelerator mass spectrometry dates (AMS) on charred bean macro remains from 10 central Plains tradition sites located in Kansas, Missouri and Nebraska suggest that this cultigen was adopted by farmers as early as the late 12th to early 13th century. As the last tropical cultigen to spread northward onto the Plains, it was added to an existing suite of farm crops, including maize, squash, chenopod, little barley, marshelder, sunflower, and maygrass. The dates add to our understanding of the timing and pathway by which beans dispersed throughout the interior of North America.

[7] Preceramic Migration and Landscape Formation along Lower Chevelon Canyon, Northeastern Arizona
Late Archaic and Early Agricultural period petroglyphs near the Little Colorado River in northeastern Arizona bear close resemblance in form and content to well-known panels along the San Juan River on the Arizona/Utah boundary. It is not clear if these similarities are due to diffusion through periodic social gatherings or to seasonal or permanent migration between the two areas. Recent survey of the region around lower Chevelon Canyon within the Little Colorado River basin has identified dozens of preceramic sites and projectile points that can help inform us on which, when, and where groups were located when creating the Chevelon glyphs. These data can be used to address issues of population movement, exchange, identity, effect of the introduction of domestic plants, and establishment of social landscapes from the Middle Archaic through Basketmaker II, 5500-1500 B.P.

Minimum Analytical Nodule Analysis (MANA) is a technique that segregates lithic raw materials into subsets of the aggregate assemblage based on color, texture, fossils, and other useful macroscopic characteristics. Lithic assemblages that have diverse raw materials that can be separated are often subjected to this sort of analysis to infer the minimum number of nodules, which informs on the technological processes that impact the lifecycle of an artifact. MANA represents a useful tool that many researchers implement into their work. It is unclear how accurate this technique is, due to many rocks sharing similar macroscopic attributes that may be lumped together, even though their provenance differs. To test the accuracy of MANA we conducted an experiment that included: a knapper producing an artificial assemblage from various raw material types, a classic MANA analysis, and a trace element analysis using Portable X-Ray Fluorescence (PXRF) technology to test the accuracy of the MANA analysis. Both techniques, classic MANA analysis and PXRF, show advantageous and disadvantageous to deducing the minimum number of nodules in an assemblage.

[65] Digital Archaeological Fieldwork and the Jezreel Valley Regional Project
Developing digital techniques for archaeological documentation has long been a priority of researchers around the world, but the challenges of deploying innovative workflows prevented measurable progress. Fortunately, recent years have seen a significant rise in the availability of previously inaccessible technologies. Since its inception in 2010, the JVRP has sought to develop digital technologies that are both cost-effective and scalable to site- and regional-level research. The JVRP is a long-term, multi-disciplinary survey and excavation project investigating the history of human activity in the Jezreel Valley from the Paleolithic through the Ottoman period. This project strives for a total history of the region using the tools and theoretical approaches of such disciplines as archaeology, anthropology, geography, history, ethnography, and the natural sciences, within an organizational framework provided by landscape archaeology. In order to effectively address these research goals, the JVRP has developed workflows for new and existing technologies such as archaeological databases, photogrammetry, 3D modeling, PXRF, and RTI. Our workflows are field-deployable and use affordable software and hardware. Considered collectively, these methodologies have allowed the JVRP to efficiently produce accurate, timely, and publishable data that is immediately accessible for collaboration by outside researchers and the public.

[27] El espacio público en aldeas formativas tarapaqueñas (Norte de Chile)

Los desarrollos formativos (900 a.C.-900 d.C.) en los valles tarapaquerios cuentan entre sus innovaciones, la construcción de conglomerados habitacionales, asociados a una cultura silvícola como al aprovechamiento de recursos del Pacífico. Nuestros estudios han permitido destacar la relevancia de las expresiones formativas tarapaquerias como sociedades tradicionales locales con una identidad territorial marcada, que no fue afecta a la impronta Tiwanaku como se ha estudiado en areas vecinas de Arica y San Pedro de Atacama. El estudio aborda las modalidades del espacio publico en Pircas-1, Caserones-1, Guatacondo y la aldea Ramaditas. Se analiza la relevancia de la dispersión de asentamientos con arquitectura en los inicios del periodo y la manera en que estas arquitecturas integran espacios comunes o publicos, asociado a formas económicas y religiosamente. Seguidamente nos referiremos a diferentes modalidades del espacio publico, considerando emplazamiento y posición arquitectónica, escala, materialidades y estrategias constructivas, que nos permiten, integrando información estratigráfica, incorporar aspectos acerca de la practica social y vida cotidiana que tuvo lugar en patios y plazas. Se sugiere cierta evolución en el rol social del espacio publico, acorde con la estructuración de un orden social y político mas homogeneamente implantado hacia los inicios del periodo Intermedio Tardío.

[205] Animal Economies, Power, and Autonomy in Central Anatolia: A View of the Late Bronze-Iron Age Transition at 9ad1r Hoyuk

In this paper we examine the nature of the Late Bronze-Iron Age transition at 9ad1r Hoyuk, a small site on Turkey's central Anatolian plateau. Specifically, we use this localized context to better understand the negotiation of power between center and hinterland in complex societies and the ability of small sites to operate autonomously within larger social systems. To do so, we monitor faunal evidence for changes in the organization of practices related to the production, processing, and distribution of both antemortem and postmortem animal resources across the Late Bronze-Iron Age divide. We look for potential shifts in social practices associated with this period of political upheaval, and we consider the extent to which the institutionalized political order mattered for provincial economies. Did imperial collapse affect the ways in which the people of 9ad1r Hoyuk made sense of their lives, and how might these changes—if there were changes at all—have been expressed materially?

[69] Late Pleistocene Occupation(s) in Eastern North America

Examination of the timing, methods of movement, routes, and origins of human migration into the hitherto unpopulated Western hemisphere has engaged archaeological inquiry for over 150 years. The last of the Pleistocene migrations by fully modern humans, and arguably the last of the great earthbound human migrations, this journey covered thousands of kilometers over the course of several thousand years, well after the movement of modern humans out of Africa (ca. 50,000 B.P.) and central and eastern Asia (ca. 45,000-40,000 B.P.). Upon their arrival, these first migrants then appear to have quickly spread throughout the entire (and then completely unknown) hemisphere within a matter of just a few thousand years, adapting to a complex and variable array of local climates, landscapes, and biota while also exhibiting concomitantly diverse technologies and lifeways on the landscape in very widely distributed locations. This paper examines and summarizes the evidence for the earliest human occupation(s) in Eastern North America and includes assessments of older discoveries like Meadowcroft Rockshelter and Cactus Hill as well as more recent research at diverse terrestrial and submerged loci.

Archaeology Should *BE* or the Double Consciousness of Historical Archaeology  
This is a paper about historical archaeology and the African diaspora. Historical archaeology is, could be, like W.E.B. DuBois's seventh son, "born with a veil and gifted with second-sight." The status of an academic field in no way compares with the ordeal of the American Negro. Nevertheless, in this paper I argue that we, too, measure our worth "by the tape of a world that looks on in amused contempt and pity." What is our relationship to history, to anthropology, to material culture, to texts, to the people who pay for our work and the people whose ancestors we imagine? In considering these questions, the power of the second-sight becomes ever clearer.

Agostini, Mark (Abbe Museum (Smithsonian Affiliate)) [172]  
Comparative Analysis of Indigenous Ceramic Technology for Two Coastal Maine Sites  
This poster presents a preliminary analysis of a donated indigenous ceramics collection excavated at the Pearsen site, which spatially correlates to the Maine State Museum investigations of the Goddard site, a large shell-free multicomponent site at the mouth of Penobscot Bay, Maine. Analysis of sherd temper type, surface treatment and decorative styles is used to first establish occupation periods at the site, and second to infer patterns of seasonality. These analyses contribute to our understanding of prehistoric cultures from Maine, and assess what appears to be differing subsistence strategies from specific local settlements at a given prehistoric time.

Agostini, Silvano (MiBACT) [180]  
Studies of Black-Gloss Pottery from Monte Pallano (Italy) II: Petrography  
This is the second of a series of four papers that report multi-faceted studies of a collection of 200 sherds of black-gloss pottery (a type of fine ware that was used for dining and wine consumption from the 5th century B.C.E.-1st century B.C.E.) excavated from the Monte Pallano ridge in the Abruzzo region of eastern Italy. Petrological approaches, based on an analytical protocol developed by the Geological and Paleontological Service of the Superintendency for Archaeological Heritage of Abruzzo–Italy, are applied to the identification and characterization of local and "imported" ware fabrics, placing them within the geological context of the Sangro valley and surrounding production areas. Variables studied include: minerals, fragments of sedimentary and igneous rocks, chamotte, fossils, "pedorelitti" if present, and other such petro-fabric typology, percentage and size of temper, paste typology (MPC-TCA), color/colors on thin section with parallel nichols view interior and exterior finishing surfaces of vessels, etc. Multivariate statistical methods reveal characteristics and differences between pottery groups to distinguish the different pastes relative to the composition (MPC), and the production technology (TCA).

A Paracas Society Perspective from the Basins of Callango and Ocucaje, Ica, Peru  
The main objective of this paper is to present the archaeological research we have carried out at two sites of relevance for the understanding of the Paracas culture (400 B.C.-100 A.D.): Animas Bajas located in the basin of Callango and Cerro Cordova located in the basin of Ocucaje. The work carried out: systematic survey, topographic mapping, excavations, architectural conservation work and analysis of materials, provides new light on understanding the Paracas culture, which has traditionally been based on ceramics or funeral textiles that are usually stripped of their archaeological contexts. Our work focused on the analysis of the architecture at the two excavated sites, and the study of settlement patterns, is gradually recognizing that the lower Ica valley, was the main area of political-religious interaction of the Paracas people. The material culture recovered in archaeological contexts also supports this premise.

An Expedient Pottery Technology and Its Implications for Ancient Maya Trade and Interaction

Coconut Walk Plain (sometimes called Coconut Walk Unslipped) was defined by Valdez et al. based on a ware from Graham. This is a coarse, fragile, and inconsistently-shaped pottery which has not been subject to detailed study until now. It is found in large quantities at sites on Ambergris Caye (especially Marco Gonzalez and San Juan). The type is most common in the Terminal Classic along coasts and rivers, but seems to have antecedents from at least the Early Classic (e.g., along the Sibun River). In this paper we report on stylistic, functional, and petrographic analysis of this pottery type and the implications of these findings for interpretations of coastal trade and interaction.

[237] Using Geoarchaeology to Expand the Interpretive Potential of Water Management Features: Investigations at the Purrón Dam in Tehaucán, México, and Ancestral Puebloan Reservoirs in the Jemez Mountains, New Mexico

From Percival Lowell’s canals on Mars to Karl Wittfogel’s hydraulic empires, water management features have long been interpreted as markers of social complexity. Yet, as Jim Neely has championed, establishing the chronology and use-life of water management features before interpreting their social significance is critical. Two dramatically different case studies highlighting the contributions that geoarchaeology can make towards understanding these features are reviewed. Stratigraphic investigations of an 8+ m sedimentation sequence impounded behind the Purrón Dam in Tehaucán, México, the largest prehistoric dam in the Americas, provided opportunities to date construction sequences and reconstruct the use-life of this feature. New dates pushed back the date of the dam’s completion from the Late Formative/Early Classic (ca. 150 B.C.–A.D. 250) to the Middle Formative (ca. 650-150 B.C.), which has significant ramifications for regional models of the rise of social complexity. Conversely, preliminary studies of 0.5 m thick deposits from small water catchment features associated with mesa-top Ancestral Puebloan communities in the Jemez Mountains, New Mexico show that these features archive paleoenvironmental records, can be dated, and hold the potential to provide insights into patterns of community aggregation during the Classic Period (A.D. 1325-1600).

Located in adjacent areas of north-central New Mexico, the Galisteo and Tewa Basins have distinct environments and occupational histories. As a result, the Prehispanic occupants had different subsistence patterns, mortuary practices, physical attributes, and health profiles. From the Late Developmental period (A.D. 900-1100) on, a growing indigenous population in the southern Tewa Basin adapted to increasing population densities through migration and changes in subsistence strategy, but with relatively little alteration of other cultural attributes like mortuary practices. Occupation of the Galisteo Basin began in the Coalition period (around A.D. 1200) period and the earliest sites and populations share few subsistence and biological traits with their contemporaries in the adjacent basin. This presentation looks at developments within each basin and considers how the environmental differences and cultural histories may have influenced biological variation.

[201] Climate Change, Culture Change? The 8.2 Ka Climate Event and the Transformation of Neolithic
Communities in Upper Mesopotamia
The so-called “8.2 ka Climate Event” is one of the most pronounced Holocene climate change events, observed in ice-cores as well as marine, lacustrine, and terrestrial records across the northern hemisphere. For the Middle East, climate models and proxy data suggest severe drought conditions about 8200 years ago. The 8.2 ka event is frequently linked to societal collapse and the demise of local Neolithic communities. However, recent excavations at the site of Tell Sabi Abyad in Syria provide solid evidence for continuous settlement during the 7th millennium B.C. and spanning the 8.2 ka event, in association with many cultural and economic transitions. Although the 8.2 ka climate event probably was among the forcing factors behind these changes, the results of the fieldwork counter the “collapse of cultures” stance with which the archaeological record is currently replete. The Neolithic communities of Upper Mesopotamia set into motion a series of mitigating adaptations, which made them well able to cope with drought and other inconveniences caused by the 8.2 ka event.

Akköprü, Ebru [249] see Mouralis, Damase

Akoshima, Kaoru (Tohoku University)
The paper examines theoretical and practical aspects of use-wear research toward a more integrated field of lithic analysis. The high magnification method already has 40 years of history. Its emphasis was laid on micro-polishes for worked materials identification. It experienced the serious “polish controversy” during 1980s, but it remains as a standard technique today. On the other hand, the low magnification method has been influential in North America, e.g., the work by G. H. Odell, as is also witnessed in recent studies in China. The variety in lithic materials led to a more complex situation. The seeming dichotomy between the methods needs to be fused to a recombinant practice of synthetic “micro-traceology”. Strength and weakness of different microwear techniques are scrutinized, and an alternative use of combined method is proposed. The data base of Tohoku University Microwear Research Team in Japan since 1976 is utilized for the objective. Experimental approach as “Middle Range Theory” constitutes the inferential framework, but more attention should be paid to actual incongruity between experiments and observed phenomena. The concept of technological organization will play an essential role for reconciliation. Case studies from the Upper Paleolithic of Northeast Japan are discussed in this perspective.

[71] Tell Abu es Suwwan: Neolithic typology and technology
Tell Abu es Suwwan is one of the Neolithic Mega-sites of Jordan, located east of the ruins of Roman Jerash, and north of modern Amman. Four seasons of excavation revealed continuous occupation during the MPPNB, LPPNB PPNC and Yarmoukian periods. These excavations produced enormous numbers of chipped stone artifacts from 45 units. The lithic assemblages from Tell Abu Suwwan included many distinct pieces that correspond with the Neolithic period and its subdivisions. Moreover, it represents a series of manufacturing stages of the lithic technology.

[219] Human-Animal Relations during the Late Moche Period of Coastal Peru: Assessing Relational Ontologies and Material Shifts over Time
Recent research conducted on the north coast of Peru at the Late Moche site (A.D. 650-850) of Huaca Colorado indicates important associations between ritually charged spaces and animal interments. The mortuary contexts yield ritualized and curated burials of camels, dogs and guinea pigs, supporting the notion that human-animal interaction was situated within a relational ontology that was specific to the communities of the Jequetepeque Valley. The contexts within which both human and animal beings were found may indicate that they were perceived as socially and spiritually co-dependent. Animals were not objectified offerings or simple economic resources but dynamic, ideological, and imbued with profound meaning. This paper will argue that social, political and cultural identities in the pre-Columbian Jequetepeque Valley as well as the larger Moche world developed through close, often intimate relationships with places, animals and things.
Alarcón Zamora, Gerardo

The emergence of complex villages, as a result of the development of chiefdoms in Central America, was an extended process that took place over a long period time across the region and even within individual sites. But the recent evidence from Guayabo de Turrialba indicates that, although the site was continuously occupied from A.D. 600-660 until A.D. 1260-1300, the period of greatest construction activity occurred between A.D. 830 and 1280. It was between these latter centuries that the structures at Guayabo de Turrialba’s site core were built. Most dates at the site correspond to the years between A.D. 900 and 1100, and could therefore be related to the increase and nucleation of the population in Costa Rica’s Central Caribbean region, which was a result of the development of complex societies in this area. The timing of these events at Guayabo de Turrialba implies specialization of production, as materialized in the building of monumental architecture such as basements, pavements, terraces and hydraulic control systems. The intensity of construction reflects consolidation of hierarchy at the site during this time.

[159] Dense Gestures: Ecologies of Rock and Art in Northern New Mexico

In the rugged canyons of northern New Mexico, basalt boulders are slowly worked upon by complex ecologies. Wind deposits clay particles; sun-heated surfaces allow microbes to fuse clay with iron and manganese producing a dark desert patina; algae and fungi produce brilliant lichen colonies that expand in patterned formations and eventually eat away rock faces together; and run-off leaves mineral deposits and staining. For millennia, indigenous rock artists participated in the ecological transformation of these surfaces—pecking, scratching and grinding into the patina to produce images of human and animal tracks, enigmatic dots and meandering lines. Drawing on Indigenous and anthropological thinking, we argue, first, that the effect of the actions of humans and environment on rock were of the same ontological order, and were perceived as such; and, second, that the coming into being of places where gestural outcomes accumulated in dense, deepening clusters was an outcome of reading the effects of such human and environmental agencies. This, in turn, was as a means of knowing and being known by sites and learning from them. The outcome of multiple gestures repeated over time, significant places were produced and represented as much by a thoughtful world as by busy humans.

[121] Ritual Banquets and Sacred Sounds in the Southern Andes: The Yamparas and the Inka

In this presentation I discuss continuities and discontinuities in local ritual practices in the Yampara territory, and Inka effects on interregional exchange networks. Located in the southeastern Bolivian Andes, this region was part of the Charcas confederation. Specifically, this paper explores the importance of copper bells and terrestrial shells in the elaborate ritual banquets of the region, the importance of sacred music in such rituals, and the ways in which access to such valuable goods was maintained despite the Inka conquest. This paper also discusses the strategies used by the native elite in the maintenance of their status and power, both at social and religious levels.

[116] A Micromorphological Perspective on Shell Midden Formation: The Case of the Mesolithic Site of Cabeço da Amoreira

The shell midden archaeological record is typically characterized by an intricate stratigraphic succession, generally underlined by a significant anthropogenic component. Thus far, the complex stratigraphy of middens has been difficult to decipher and few studies have focused on the microstratigraphic record of midden formation. The present paper on the Cabeço da Amoreira sequence discusses ongoing geoarchaeological and micromorphology studies that have been geared to investigate aspects pertaining to site formation, the degree of assemblage integrity and the nature of anthropogenic signatures at the site. The preliminary results attest to the intensity of anthropic depositional processes and their impact on sedimentary lateral variability. The role of the microscopic level of analyses to access behavioral activities and taphonomical aspects is shown to be additionally relevant in shell midden investigations.

[329] People, Potters, or Pots: The Transmission of Stylistically Similar Ceramics in the Late Uruk

Archaeologists have long puzzled about how best to interpret the appearance of stylistically similar ceramics and ceramic complexes between neighboring or distant regions. Do such finds represent interregional exchange, movements of individual people or populations, the activity of itinerant potters, or some form of broadly shared socio-cultural activity? An INAA trace element analysis of a collection of ceramic tools used by Late Uruk era potters allows us to address the question of whether itinerant ceramic specialists were active in the Late Uruk, moving within and between broad regions and serving as a motive force in the transmission of the Late Uruk ceramic complex. By focusing on the tools used by ceramic specialists rather than the vessels themselves, we are able to directly address questions about the activities of specialized potters in Late Uruk society. In terms of the Uruk Expansion, the results of our study suggest that the broad interregional similarities in Late Uruk ceramics are more likely related to the movement of ideas than to movements of products or people.

[72] Norias, Cenotes, and Rejolladas: Changes in Yucatán’s Hydrogeologic Landscape after the
Spanish Invasion
The introduction of the noria (waterwheel) on the Yucatan peninsula after the Spanish invasion revolutionized the use of karst hydrogeologic solution features known as cenotes and rejolladas. In this paper we draw on Michael Schiffer’s framework for studying technological differentiation to analyze changes in the design of water lifting devices and the groups who used them from 1546 to the present. We consider how adoption of the noria shaped changes in agroecology, animal husbandry, and the production of cash crops, such as dyes, sugar, and henequen. We also examine how the architectural and spatial contexts in which norias were embedded reflect variation in aesthetics and power relations between native and non-native groups.

The Negatives and Positives of Preserving Iowa’s Archaeological Photographs
The photographic collection at the Office of the State Archaeologist (OSA) at The University of Iowa (UI) documents the history of the last half-century of archaeological research in Iowa and serves as a record of the cultural artifacts associated with many historically significant sites. The archaeological community relies on this indispensable set of records to fully understand and interpret the history and prehistory of the over 2,000 archaeological sites documented by these photographs. Since the photographs represent the only copies of critical visual field information, their degradation, accidental destruction, or theft would result in irreparable loss of scientific and historic research data for these sites. In 2008, the OSA began a two-phase project to enter the records into a bibliographic database and convert slide, negative, and print format images into high-resolution, archival quality digital files. Scans are available through two online portals: I-SitesPro includes access to the full collection for professional archaeologists, and the UI Digital Library provides general public access excluding confidential site information and culturally sensitive material. Scanning is ongoing and will grow the collection to over 80,000 digital images by the project’s end.

Ethnic and Political Identity in the Southern Maya Lowlands
The indigenous regions and territories in the Southern Maya Lowlands suffered severe changes after the Spanish conquest. It is extremely difficult to understand the political, ethnic and economic alliances between peoples, regions and territories in this area on the eve of the Spanish conquest. The arrival of the Spaniards to the region changed drastically the ethnic and political categories between the different Maya groups, making their cultural and territorial demarcations even more confusing. The Spaniards couldn’t understand if the peoples they encountered were different ethnic groups or if they were factions of a single group. Some Colonial documents refer to the Itza as the “Itza nation”. We discuss in this paper if the Itza can be considered as an integrated polity or not, as well as the role played by their parcialidades. We further attempt to analyze the relationship of the Itza with their Maya neighbors such as the Lacandon, Manche Chol, Mopan and Xocmo.

Approaches to Social Complexity in Kura-Aras Culture: A View from Köhne Shahar (Ravaz) in Chaldiran, Iranian Azerbaijan
Despite decades of studies on so-called Kura-Aras/Early Transcaucasian Culture and increase of our knowledge about many aspects of it, yet the nature of this phenomenon has been a mysterious aspect and difficult to address. Indeed, there are some fundamental questions about the Kura-Aras Culture that remain for further investigations. Several reasons might have been listed here but one of them could be the nature of data and record at disposal. One of fascinating Kura-Arasian sites, Köhne Shahar (Ravaz) in Chaldiran area in Iranian Azerbaijan, suggests some promising data. Based on preliminary investigations at this site, I will show that the site has great potential to address these fundamental
ABSTRACTS OF THE SAA 79TH ANNUAL MEETING

questions. Although Köhne Shahar (Ravaz) is not a typical Kura-Arasian settlement and rather represents a unique one, however, understanding internal social structure of the community at the site may lead us to other aspects of the Kura-Arasian society in general.

[329]  Testing the Evidence: A Follow-up Study of Late Uruk and Proto-Elamite Ceramics from Tal-e Geser, Iran
Several years ago, the authors carried out an INAA analysis of ceramics from Tal-e Geser, a site in the Ram Hormuz Plain of Southwestern Iran. The results were provocative: the Geser material seemed to include a large component of pottery that was manufactured somewhere else and then carried to Geser. The main component of the introduced material had trace element signature comparable to Tepe Farukhabad in the eastern end of the Susiana Plain, but the imported ceramics included at least one sherd with a trace element signature matching southern Mesopotamia. The initial study's results also showed changing patterns of ceramic imports at Geser between the Late Uruk and Proto-Elamite periods. Most interestingly, it identified three Proto-Elamite era sherds from highland Iran with what appears to be a Geser trace element signature. These results were unusual enough that we felt they needed to be tested with a second stage set of samples. This paper presents the results of that study.

[258]  "But Is It Academic?" Reflections on a Year of Archaeology Blogging
Good news: web platforms like Wordpress, Tumblr, and Google’s Blogger make starting an archaeology blog incredibly easy! Bad news: once you start a blog, you actually have to create content and post it online. As with academic writing, maintaining good writing discipline is of key importance, but creating for a blog also requires a lot of different skills. I have started three blogs, abandoned two of them, and created content on digital archaeology for over a year. Here is what I learned as a neophyte blogger about how my targeted audience may not be the same as my actual audience, how to keep going after the first post, where academic writing fits in, and how to stop worrying and learn to press the “publish” button.

[172]  The Organization of Lithic Tool Production and Use at Two Sixteenth-Century Iroquoian Sites
Fieldwork at two Cayuga sites, Parker Farm and Carman, has shown differences in both the intensity of occupation and spatial structure of the settlements, suggesting the sites may have differed in function and degree of permanence. Results from a previous analysis on stone tools indicate overall similarities in the categories of tools recovered from both sites, but also significant differences in the relative proportions of tool types. In our current research, we examine the spatial distribution of these lithic tools and the co-occurrence of various tool types within specific site areas to further investigate the spatial organization of activities once occurring at these sites. Are activities segregated in separate locations? Does gender affect the distribution of lithic tools? Are some tasks consistently performed in similar locations? An analysis of the spatial structure of stone tools will provide a better understanding of the behavior responsible for the differential patterns of occupation at these sites.

[262]  The Chronology of Fremont Farming in Northern Utah
Fremont maize cultivation in northern Utah occurred at the northernmost extent of prehistoric Native American horticulture west of the Rocky Mountains. Fremont chronology currently relies almost entirely on a large database of radiocarbon dates, but most of the existing dates are on wood charcoal subject to old wood problems; dated charcoal also often has unclear associations with maize or other cultural materials. Recent efforts to directly date archaeological maize from museum collections have helped refine the chronology of Fremont horticulture. These new dates indicate that the timing of the earliest appearance of maize varies across northern Utah, and that in some areas maize horticulture continues later than previously thought.

[106] Investigations at Saint Colman’s Abbey: An Early Medieval Irish Insular Monastery
Saint Colman’s Abbey is situated on the eastern end of Inishbofin, an island off the coast of Co. Galway, Ireland. The site currently consists of a 14th-century church and a modern graveyard that remains important to the local population. However, the Venerable Bede reported that the settlement was first established ca. A.D. 667 by an Irish saint who fled England after a church synod repudiated the Irish method of monastic practice. Recent field survey was undertaken to identify features on site that could be associated with this earlier phase of monastic activity. This multi-year survey has revealed several extant components common to Irish early medieval monasteries, including a circular enclosure wall, leachta or prayer stations, medieval cross-slabs, and a possible mill pond. These components are compared to architectural, spatial, and religious elements of other early medieval monasteries, such as those on Inishmurray, Co. Sligo and High Island, Co. Galway. The identification of these features reveals how the material culture of early monastic practice has provided a framework for local lay worship over many centuries.

[110] Building Cahokia: Transformation through Tradition
Architecture was used to mark purpose and meaning at Cahokia in ways that were unique in pre-Columbian North American societies. Temples, meeting houses, sweat lodges, charnel houses, and other sacred structures as well mundane houses and storage huts, each with its own architectural signature, populated Cahokian settlements and ritual centers. Here, I present new evidence from Emerald Mound, a Cahokian center, and other towns in the region that documents how the new architectural forms were invented through engagement with and citation of the traditional. I further suggest that these novel architectural forms, their emplacement, and their organization created a new relational field that engendered a new worldview and a new power of place and persons.

[25] Identity in a Multiethnic Neighborhood Center of Teotihuacan: Cephalic Modification, Headdresses, and Facial Paint
During 13 field seasons of extensive excavations by Linda Manzanilla and her team in the neighborhood center of Teopancazco, Teotihuacan, Mexico, skeletal remains from 129 individuals were recovered. We discuss in this paper evidence from this dataset of cranial modification. For example, 38 individuals had been decapitated, some covered with cinnabar, and seven individuals demonstrate evidence of cephalic or cranial deformation. Cephalic modification seems to have been a visible marker of ethnic identity, and a means of differentiating people within a multiethnic society. In such a multiethnic community, where several languages were probably spoken, visual signs such as cranial modification and face paint may have been important visual signs for social differentiation and identification.

The Role of Hog-Nosed Skunk in the Subsistence of Hunter-Gatherers of the Pampean Region of Argentina

Hog-nosed skunks (Conepatus chinga) are native carnivores with crepuscular and solitary behavior. They are notorious for their anal scent glands, which serve a defensive purpose. Although skunk bones are not very common in archaeological sites, the degree of interaction between skunks and pampean hunter-gatherers has not been discussed in detail. The objective of this paper is to present and discuss evidence of this species in Paso Otero 4 (PO4, pampean region of Argentina) and to evaluate its presence at a regional scale in order to more broadly discuss the role of skunk in human prehistory. Moreover, information from chronicles and historical documents were compiled to generate hypotheses about the potential use given to this resource during the Holocene. In PO4, 13 hog-nosed skunk specimens were recovered and dated between ca. 8900 to 4600 years B.P. Cut marks, thermal alteration, and tooth marks on these remains were identified. A detailed evaluation of tooth marks was conducted and double arch punctures and crescent-shaped pits which are characteristics of human chewing were recognized. Results enable us to propose that this animal was an occasional prey for hunter-gatherers and was more common in the local faunal repertoire than previously believed.

Imaging a Language: New Visual Approaches to Document Ancient Writing Systems in El Salvador

New visualization tools allow a different approach to documenting and contextualizing ancient writing systems. Gigapan technology allows the capture of graphic elements in ways that the detail is never lost despite the scale of the image, allowing the researcher to move in and out between elements without losing contextual perspective. Furthermore, the same technology can be used to propose movement and structure within the visual realm to convey possible visual stories as intended by the ancient artist. Although these methods are new and exploratory, they offer a fresh approach to recording methods and interpretative representations of the graphic elements that on their own have little to no apparent meaning.

The Cave within the Hill: Sacred Symbolism of Landscape and Rock Art Figures Belonging to Rainmaking Ceremonies in the Sonoran Desert

This paper intends to define the relationships that could have existed between the exercise of political and religious power, the construction of monumental sites, and landscape symbolism—associated with a cosmological system, derived from the mythological cosmogony—in Cerros de Trincheras in the Sonoran Desert of northwestern Mexico. The analysis of archaeological evidence, regional ethnography and ethnohistory allows us to formulate certain hypothesis and to propose a systematic comparative study of concepts and cultural practices that have its origin in Mesoamerica and were shared by the cultures of the American Southwest. These include: astronomical observations, construction and alignment of architectonic structures, ritual calendars and productive activities. In this specific case, religious symbolism of hills and elevated sites, linked to rain and abundant crops petition rituals, is emphasized. This must have been an essential ritual function of the hill sites that are found in the dry environment of the Sonoran Desert, where water is the most precious good that allows the subsistence and prosperity of a society depending on agriculture.

An Early Navajo Sun Watching Site in Chaco Canyon: Critical Evaluation Using Monte Carlo Null Test Criteria
We have found direct evidence of Navajo seasonal sun watching at an early Navajo site in eastern Chaco Canyon. The core and much of the periphery of the site out to approximately +/- 0.5 km has been surveyed. It is well known that historical and present-day Navajo place importance on sunrise, often orienting the door of a newly constructed hogan to the direction of the rising sun on that day. The Navajo language includes multiple words for degrees of sunrise. However, reports of solstice and equinox observations are rare in the literature. We believe this is the earliest Navajo site denoting both awareness and precise observation of the equinoxes and both solstices. We make this assertion based on three tests: (1) Iconography consistent with seasonal observation; (2) Multiple viewing points defining alignment with solstices and equinoxes; and (3) Monte Carlo evaluation for false positives given the parameters of the site. Both our research design and the results of these tests will be given for winter and summer solstices and the equinox.

Macroscale temporal and spatial variation in projectile point form has long been of keen interest to North American archaeologists. Where microscale variation is observed, exploring it can be hindered by small samples. Two adjacent communities on the Lower Columbia River floodplain have strong multilevel, microscale variation in projectile point form. The combined sample for both sites is approximately 3200 points. The two are contemporary (ca. A.D. 1400-1830), 8 km apart and occupied by the same ethnic group. Households at both resided in enormous plankhouses. Meier contained a single structure, while Cathlapotle had six. Excavations at Cathlapotle focused on houses 1 and 4. Four of the Cathlapotle structures were divided internally into compartments while the Meier house was internally open. As previously shown, the sites contain the same projectile point types, but in significantly different proportions. At Cathlapole, houses 1 and 4 have different frequencies of types (House 4 has the same type as Meier), while the three excavated compartments of House 1 display very different frequencies of points among them, including rare points virtually absent elsewhere. These households and segments differ in status and while there was community level production specialization, there was fluidity at the household and household levels.

The Azraq Marshes Archaeological and Paleoenvironmental Project (AMAPP) is a team of international researchers studying the importance of the Azraq wetlands for hominin populations throughout the Pleistocene. Located ca. 200 km east of the Mediterranean coast in Jordan’s eastern desert, the Azraq wetlands—the Druze Marsh in the north and the Shishan Marsh in the south—have provided a consistent water source in what is otherwise a hyper-arid environment. Ongoing research since 2009 indicates that the northern wetland acted as a desert refugium for hominins during adverse regional conditions, whereas during more humid periods when the marshes expanded in size, populations moved into the surrounding landscape along the banks of rivers. Results from the 2013 field season suggest the southern wetland is equally important to the regional settlement history. Initial excavation in the Shishan Marsh identified a high intensity (more than 500 lithics > 2 cm per cubic meter) Middle Pleistocene occupation horizon characterized by bifaces and flakes in relatively pristine condition. The associated faunal assemblage, although fragmentary, is indicative of savannah adapted species, such as large Equus, small Gazella, and rhinoceros. Future research will expand the excavation to determine the precise timing and nature of Paleolithic occupation at the site.

[69] Late Pleistocene Archaeology of the North American Great Plains
What was once considered the Pleistocene gateway to the Americas has become relegated to interior continental hinterland. Evidence of pre-Clovis occupations exist but remain inscrutable in many ways. The entryway role of the ice-free corridor during MIS 2 (Late Wisconsinan) seems minimal at best, meaning that initial colonists of this region did not enter from the north. Those who eventually reached this deep interior of North America found verdant grasslands with a rich faunal biomass. Colonization proceeded rapidly with the appearance of Clovis and Folsom groups in this region. The relationship between the pre-Clovis and Clovis archaeological records remains unclear, but Clovis groups seem to be immigrants into this province (perhaps from the southeast). Clovis inhabitants may have been pre-adapted for exceptional success in this savannah environment because of distinctive technological and settlement strategies which promoted colonization through rapid landscape learning. In contrast, Folsom groups seem to represent a distinctive regional response to the emergence of the bison dominated Terminal Pleistocene grasslands. The origins of these highly distinctive Folsom adaptive strategies seem rooted in earlier Clovis patterns in the interior grasslands. Both groups were required to cope with shifting environmental conditions offering unique regional opportunities as well as constraints.

[167] Sacrifice, Sexuality, and Power in Late Classic Maya Ceramics
This paper will provide an analysis of a selection of Late Classic Maya ceramics with a focus on sacrifice through gendered ritual and sexuality. While focusing on gendered depictions of sacrifice (some seemingly sexualized or erotic), of further consideration is the role additional characters such as animals, assistants, dancers, and deities play in these artistic programs. In some examples, the idea of reciprocity is apparent.

[18] The Physical Landscape and Paleoclimates of the San Juan Basin
The San Juan Basin in northwest New Mexico is a semi-arid landscape characterized by sandstone mesas dissected by ephemeral drainages. Rainfall is unreliable and temperatures extreme. Yet, it is home to the Chaco culture, one of the largest, most complex regional centers of pre-contact North America. The NGWSP project area includes two linear transects on either side of Chaco Canyon, essentially providing a random sample of archaeological sites and associated geomorphic landscapes. We explore the settlement patterns in this region in terms of geomorphic characteristics and associated landforms. Indeed, alluvial, eolian, colluvial, and mesatop sites each provide challenges and opportunities to a successful livelihood in terms of farming practices. A high-resolution record of dendroclimatically reconstructed paleoclimates aids in our investigations.

Anderson, Patricia (CNRS, Nice, France)
[22] Fiber Use in Northern and Central Tunisia by Sedentary and Semi-Nomadic Populations
An ongoing ethnoarchaeological study in 2 different regions of Tunisia shows some similarities and some distinctive differences in use of fiber. Most commonly, the leaves of two wild grasses used in each region undergo different harvest and treatment processes for making objects: Ampelodesmos mauritanica (called diss), located only in Northwestern Tunisia, is used by the sedentary agricultural/pastoralist population, and Stipa tenacissima (called Alfa), found only in the central high steppic region, is used by both sedentary herders/farmers and by seminomadic herders. Although some objects made from both kinds of grass are similar (ropes, baskets, double baskets for transporting materials on animal back, mats, etc.), there are some important differences, including what they were used to transport. Other differences are that in the central region, Alfa leaves are woven on a loom to produce a distinctive thick mat (hassir) used in homes, but never during transhumance periods, and sedentary and semi-nomadic herders make bags and tents from goat hair. In the Northwest the robust stems of diss are used for making roofing mats, and even furniture, and cereal stems are used to make large circular structures for storing grain in rooms.

[28] Linking Health and Marriage Practices among Commingled Assemblages: A Case Study from Bronze Age Tell Abraq, UAE
Tell Abraq (2200 B.C.-100 A.D.) is the largest prehistoric site on the southern coast of the Arabian Gulf. A mortuary tomb at the site was used for a 200 year period (2200-2000 B.C.) and a minimum of 276 adults and 127 subadults were commingled in the tomb. Analysis of 175 adult second cervical (C2) vertebrae resulted in the discovery of potentially a rare pathology: congenital agenesis (non-development) of the dens. Seven (4%) of the 175 C2 vertebrae presented this pathological anomaly, raising questions about the reasons for such a high prevalence.

Previous analysis (Baustian 2010) of subadults from the tomb revealed very high rates of pre-term and neonatal mortality (31.4%, n = 40). Circumstances leading to the death of such a large number of infants were explored, demonstrating that only some infants died as a result of infectious disease. As an alternative explanation, consanguineous marriage (long prominent in the region) was suggested as a factor in the high rates of infant death. These two independent studies reveal that commingled assemblages are still capable of providing nuanced information about social processes of the living community. In this instance, it is possible to infer how marriage practices may have impacted human health in this community.

[31] The Role of E-Group Architecture in the Development of Maya Astronomical Knowledge
When Frans Blom mapped Group E at the Maya site of Uaxactun, Guatemala, in the 1920s, he noted an alignment between the three buildings on the eastern side of the group and the pyramid on the group's western edge. He documented that if an observer stood on the steps of the pyramid they could witness the sun rising over each of the three eastern buildings on the Equinoxes and the Summer and Winter Solstices. As archaeological research continued in the Maya region, similar groups began to be documented and referred to as E-Groups. Yet, while other E-Groups appeared similar, they lacked the precise alignments found at Uaxactun. Over the years, archaeoastronomers have proposed alternative alignments, but generally these proposals have resulted in interpretations that work for some, but not all, E-Groups. As a result, most scholars have pulled away from Blom's observatory hypothesis. This paper seeks to revivify the observatory hypothesis by proposing that the earliest E-Groups served as generalized observatories focused on the ecliptic, rather than specific solar observatories, and as a result, these structures could have been used to produce the data which underlie the astronomical tables found in the later Postclassic Maya codices.

[151] Using CRM Data for “Big Picture” Research
The vast quantity of information generated by CRM archaeology has revolutionized our understanding of the past human occupation of North America. In most regions the numbers of recorded sites, reports, and collections have grown a hundredfold since 1974, resulting in information and materials maintained by a myriad of state, federal, and public and private institutions. Managing this information so that it may be used to address research and management questions has proven a major challenge that people throughout the profession have risen to in innovative ways. Archaeological data is being employed at an array of geographic and temporal scales, and linked with a wide range of data categories encompassing aspects of physiography, climate, and biota, in the past and at present. Predictive and settlement modeling projects at the locality to subregional scale examining thousands of sites are commonplace, and regional and continental scale analyses of past population distributions are emerging, facilitated by projects like DINAA, NADB, Open Context, PIDBA and tDAR. Documenting and accessing collections data online, and using geophysical and remotely sensed data at increasingly larger scales, are other examples of big picture research in the exploration of big questions that is becoming common practice in American archaeology.

Anderson, J. Heath (Minnesota State University)
[275] Obsidian Consumption in the Tula Region after Teotihuacán’s Decline: A View from Cerro Magoni
Over the past 30 years, Dean Healan’s work in Mesoamerican obsidian studies in general, and obsidian production, distribution, and consumption in the Tula region in particular has revealed, among other things, valuable insights about the relationships between politics and economic exchange. Specifically, his work on Epiclassic obsidian from Tula Chico has given scholars the first indications of how the Epiclassic economies differed from their Classic period antecedents and, ultimately, an important perspective on the processes involved in the regeneration of complex society in the form of the Toltec state. In this paper, I share new data from Cerro Magoni, an Epiclassic site that, along with Tula Chico, might have been politically comparable to Tula Chico. I discuss the implications of obsidian consumption in the Tula region as a way to conceptualize the relationships between economic, social, and political processes involved in the formation of the Toltec state.

Anderson, Meredith (University of Iowa)
[287] Re-examining Teotihuacan’s Classic Period Obsidian Network through Patterns of Consumption: A View from the Hinterlands

Research on the economic development of the prehistoric state and its relationship to its hinterlands offers insight into how and to what extent politically complex societies functioned and were sustained. Examination of trade networks, in particular, has been instrumental in addressing important archaeological questions, specifically with regard to the role of the state and the extent of its governance over raw materials. Teotihuacan, along with its outlying markets and associated hinterlands, became Mesoamerica’s principal economic force during much of the Classic Period. That Teotihuacan’s obsidian market played a role in its development is generally accepted. What is less clear is how significantly the obsidian trade contributed to Teotihuacan’s expansion. Using X-ray fluorescence sourcing, this study assesses the procurement strategies demonstrated at several rural sites situated on or near major proposed trade routes, with the expectation that site function correlates to distinctive procurement strategies, specifically with regard to the types of obsidian artifacts found on site, their sources, chronology, and context.

[315] A Debitage Analysis of the Clovis and Early Archaic Components at the Topper Site

Recent excavations of the upland portion of the Topper site in Allendale County, South Carolina have focused on areas with dense Clovis and Taylor occupations. In this study, we attempt to characterize the unique aspects of, and quantify the differences between, lithic debitage from the two components, and to identify assemblages from other areas of the site that lack temporally diagnostic artifacts. To this end, mass analysis of the entire assemblage from one 4-x-4-m block, as well as attribute analysis of mapped flakes, was employed. This debitage analysis complements and is aided by ongoing research on the Clovis and early Archaic materials from the upland portion of the site, including lithic refitting, spatial analysis, detailed analysis of tools, and radiocarbon dating.

[152] Engaging and Empowering Citizen Archaeologists through the Co-Creative Process: A Case Study Involving the Oklahoma Anthropological Society

Like many avocational archaeological groups across the nation, the Oklahoma Anthropological Society (OAS) has struggled in recent years to meet the needs and interests of community members. To address
this challenge, in spring 2013, OAS leadership requested our help to revitalize the group’s membership and its recently shelved archaeological certification program. To ensure a co-creative approach to the reshaping of OAS, our approach to providing assistance began with an ethnographic study of the OAS membership—using methods including participant observation, individual interviews, and survey administration—to establish member values and goals. We then compiled these data and used them to develop concrete proposals for a revised OAS certification program and for reaching out to a broader cross-section of Oklahoma citizens than had traditionally been the case. Finally, we offered the proposals back to OAS membership for comments and suggestions for improvement, and revised the ideas accordingly. Our paper overviews the methods and results of this collaboration between professional and avocational archaeologists and reflects upon the success of our co-creative effort to improve public archaeology programs and educational opportunities in the state of Oklahoma.

[24] Folsom in the Mountains: Over a Decade of QUEST Research in the Upper Gunnison Basin, Colorado

Like other areas of the Rockies, the Upper Gunnison Basin contains a rich late Pleistocene archaeological record, especially for the Folsom period. Research supported by the Quest Archaeological Research Fund began in 2002 at the Mountaineer Folsom site, and has revealed one of the richest and most spatially extensive Folsom sites in North America. The most striking feature of the site is a complex of contemporaneous habitation structures which, along with other evidence, suggests that the site served as a relatively long-term overwinter residential site. Excellent horizontal preservation at the site has provided a source of data that can be used to examine site structure, technological organization, and social dynamics. Quest funds have also been used to investigate other late Pleistocene sites in the Basin (including the Lanning and Flat Top sites) and to collect and analyze the paleoenvironmental data needed to construct a framework in which the Paleoindian archaeological record can be situated. From these studies we have learned that, far from being peripheral, the central Rockies were a core area for Folsom groups in North America.

[253] Commoditizing the Sacred: The Exchange of Jade Blanks in the Maya Lowlands

Despite the fact that jade was one of the most precious materials for the Maya, very little is known about the way it was worked and exchanged. By reanalyzing the jade collection from Cancuen, a Late Classic production center in the Peten region of Guatemala, I show that most of the production from this workshop was exported to recipient sites as preforms, that is to say as objects that could be easily commoditized. These blanks were exchanged and transformed into meaningful items in the recipient sites, where they changed status and were then gifted between elites. Such organization shows the complexity of wealth goods production and exchange in the ancient Maya world.

[160] Hunter’s Best Friend: An Analysis of Dogs and Independent Hunters in the Coast Salish Area of the Northwest Coast

Dogs have been an immense help for hunters in the past, just as they continue to be for contemporary hunters. In this essay, we maintain that dogs would have become increasingly important for hunters after the widespread adoption of the bow and arrow. We examine this possibility for Coast Salish cultures of the Northwest Coast, comparing canine faunal results before and after 1600 B.P., when the bow and arrow came into broad use throughout the Salish region. Ethnographically, Coast Salish hunters using the bow and arrow hunted alone or in pairs, a scenario that was less likely prior to 1600 B.P. when
hunters collectively hunted using atlatls and darts. We postulate that hunting dogs greatly facilitated this shift towards individualistic hunting, for their ability to track and corner prey. We present the ethnographic evidence for hunting dogs associated with independent hunting from numerous Coast Salish cultures. Furthermore, we will detail our analysis of the faunal record, which reveals that domesticated dogs increased substantially as a portion of the faunal record after 1600 B.P. Accordingly, hunting dogs helped enable greater autonomy for Coast Salish hunters, as much as the bow and arrow technology.

Incised Stones from the Chance Gulch Site, Gunnison County, Southwest Colorado

Chance Gulch is a multi-component campsite located in the Gunnison Basin of southwestern Colorado, with evidence for prehistoric use ranging from the late Paleoindian through historic eras. The upper 5-10 cm at the site comprise and compress occupations spanning the Late Prehistoric time frame to the present and yielded an assemblage of about a dozen incised stones. Similar stones have rarely, if ever, been documented in Colorado, and their closest analogs (as other papers in this session attest) appear to be most commonly recovered in the west—particularly in Utah and Nevada. In this talk, we focus on characteristics of the Chance Gulch incised stones that include their stratigraphic context, raw material types, design elements, manufacturing technique, and microscopic signatures. We offer inferences regarding the stones’ possible function(s) and cultural affiliation and contemplate why they occur at the Chance Gulch site and not others—at least not to our knowledge—in the Southern Rocky Mountains.

Lidar and Settlement Survey of Izapa, Mexico

Izapa was a major Pacific coast site containing hundreds of stelae with distinctive carved iconography. However, nothing was ever documented beyond the site center leaving regional population patterns unknown. To fill this gap in our knowledge, the Izapa Regional Settlement Project targeted three adjacent environmental zones for survey. Regional-scale LiDAR data were collected from the piedmont and low hills to document settlement while ground-truthing dated them. In addition, on the coast plain, pedestrian survey took advantage of extensive drainage canals to document hectares of prehispanic settlement.

These LiDAR and pedestrian survey data are used to infer how relative population changes correspond to the political organization at Izapa. Both coastal plain and low hills were densely populated by the Conchas phase when La Blanca was the largest center in the Soconusco, but the piedmont was only sparsely populated. Then, after 850 B.C. the coastal plain was virtually abandoned and occupation shifted to the piedmont where Izapa was built; and population levels persisted in the intervening low hills. Population nucleated around Izapa at its Late Formative apogee and then the site was abandoned during the Terminal Formative period, but population levels on the piedmont rose overall but with more dispersed settlement.

The Persistence and Organization of Chipped Stone Tool Production among Stó:lō-Coast Salish Households in Southwestern British Columbia: the Analytic and Interpretive Significance of Small Debitage

Despite an enduring analytic emphasis on lithic technology in archaeological studies of southwestern British Columbia, the interpretive significance of debris smaller than 6.2-mm mesh—a standard of field archaeology in the region—has not been fully explored. Full retention and laboratory sorting of screen residue generated during subsurface investigations at Welqamex (DiRi-15), has yielded lithic assemblages comprising as much as 70% of flakes and shatter captured only with 3.22 (or smaller) mesh. We argue that these small assemblages are critical to the inferential reconstruction of daily practices and labor organization at the household level. This poster highlights the results of aggregate and individual flake analyses that incorporate these small-debitage assemblages. We present preliminary
findings addressing diachronic change in the organization and variability of residential-based chipped stone tool production practices following Stó:lo-Coast Salish incorporation of iron tools, muskets, and other technologies into household material culture.

Antonites, Alexander [4]  
*Political and Economic Interactions in the Hinterland of the Mapungubwe Polity, ca. A.D. 1200-1300, South Africa*

The thirteenth-century A.D. was a period during which northern South Africa, southern Zimbabwe, and eastern Botswana saw the development of a centralized authority seated on the town of Mapungubwe. To date, research has tended to view the hinterland around Mapungubwe as inconsequential in the larger social, political and economic transformations that resulted in centralized authority. New research on communities located in the northern Soutpansberg mountains—a region on the southern margins of Mapungubwe’s influence—suggests a reappraisal of this hinterland as inert and un-influential in regional dynamics. Contrasting patterns of consumption and production between the Mapungubwe hinterland and heartland suggest that hierarchy formation in the heartland co-occurred with the horizontal expansion of social relations through networking strategies in the hinterland. Evidence suggests that political power at Mapungubwe was counterpoised between maintaining generalized subsistence production within the heartland and more intensive efforts to acquire trade goods produced by communities on the margins of the state. The distribution of prestige items suggests that these communities were able to use their position to acquire trade goods usually considered restricted to elite spheres of society in the heartland.

Antonites, Annemari (Yale University) [40]  
*Animal Exploitation in the Limpopo Valley, South Africa*

This paper presents the zooarchaeological results from Schroda, a 10th-11th century regional center associated with the rise of complex societies in southern Africa. At around 1000 A.D., Schroda’s influence declines due to a shift in regional sociopolitical dynamics. The effect of this shift is apparent in a number of material culture categories, including the animal bones. I consider the social implications of continuity and change in the daily exploitation of animals during this regional development.

*Changing Perspectives on Pithouse Period Occupations in the Mimbres Region*

When the Mimbres Foundation began research in the 1970s, little more was known about the pithouse period occupations than Emil Haury’s pioneering work of the 1930s that defined the Mogollon archaeological culture. Pre Classic Mimbres archaeology was known, but understanding was limited. The Foundation’s research identified a previously unknown pithouse period associated with plain ceramics, refined the chronology of the pithouse occupations associated with slipped and painted ceramics, and provided a rudimentary understanding of pithouse period social dynamics. In the past four decades, as a result of much new research, our comprehension of the pithouse periods has improved dramatically. It is now clear that pre Classic social interaction, social identity, and community organization was dynamic, complex and fluid. Pithouse period populations underwent fundamental shifts in the ways they organized themselves, their sedentariness, their organization and community cohesiveness, and their connections with populations near and far. We evaluate the impacts of the Mimbres Foundation, the current state of research, and prospects for the future of Mimbres region pithouse period archaeology.

*Archaeological and Paleoenvironmental Investigations in and around Ceibal, Guatemala*

This paper discusses the results of archaeological and paleoenvironmental investigations in and around Ceibal, Guatemala, in order to examine diachronic changes of Maya sociopolitical organization in relation...
to environmental changes. In 2011, 20 series of sediment cores were obtained from the deepest parts of several lakes in the southwestern and central Petén. In particular, annually laminated lake sediments (varves) were confirmed from Lakes Petexbatun, Las Pozas, and Quexil for the first time in the Maya area. The laboratory analysis of the samples allows us to reconstruct the high-resolution past environment and climate changes during the Preclassic and Classic periods.

Aporta, Claudio  
[73] Land, Snow, Ice, and Water: Reflections on the Physical Nature of Inuit Routes  
Routes have been marginally considered by archaeologists looking at patterns of residence and migration of Arctic occupation. Migration routes have been broadly postulated (as direction and locations of movement), in order to make sense of key findings in archaeological sites, through envisioning migration trajectories of paleo-Eskimo and Thule groups. This paper will argue that serious consideration of contemporary Inuit trails could help gain a better understanding of Arctic human geography and human history. This paper will: (1) discuss the physical nature of Inuit summer and winter Inuit routes; (2) analyze the physical markings of Inuit routes on open water, snow, ice, and land; and (3) reflect on the historical and geographical dimensions of these routes, and what these findings mean for understanding human occupation of the Arctic.

Aquino, Valorie (University of New Mexico), Douglas J. Kennett (Pennsylvania State University), Norbert Marwan (Potsdam Institute for Climate Impact Research), Sebastian F. M. Breitenbach (Eidgenössische Technische Hochschule (ETH)) and Yemane Asmerom (University of New Mexico)  
[201] Climate Volatility and the Classic Period Maya Political Landscape  
Multiple studies in the past 20 years support the hypothesis that environmental change—particularly severe, protracted droughts and deforestation/soil degradation—contributed to widespread abandonment of Classic Period Maya polities (A.D. 300–900). Questions remain about the specific magnitude and geographic extent of these environmental perturbations, as well as how complex environmental processes affected the local resilience or vulnerability of social, economic, political, and ideological systems. Archaeological and historical data indicate, however, that the long-lived Classic Maya tradition of divine kingship unraveled between A.D. 750–900, along with the asynchronous disintegration of the polities they governed. The legitimacy of these divine kings was based upon assertions of unique supernatural and ritual authority; thus, the predictability of rainfall and crop yields were vital factors in strengthening, preserving or eroding community support. In this paper, we present a climatic volatility index for the Classic Period derived from a high-resolution speleothem paleoclimate archive from the southern Maya lowlands. Based on a comparison of this index to the available data on dynastic histories, subsistence strategies and site expansions/contractions, we argue that climate volatility played an important and under-appreciated role in destabilizing Classic Period systems of governance.

[43] Canal Junction, What’s Your Function? A New Type of Water Control Feature in Hohokam Canals  
For over a millennium, Hohokam farmers in the Salt River Valley employed impressive engineering skills to construct their extensive canal systems. During the spring of 2012, Desert Archaeology, Inc. conducted a data recovery project near the headwaters of Canal System 2, the largest prehistoric irrigation network on the north side of the Salt River. Five main trunk canals, along with 12 smaller distribution canals, were identified over the course of field work. A surprising find was the occurrence of large, first-order distribution canals that branched from a main trunk canal. Excavation at one of these junctions revealed a well-preserved adobe and cobble weir that reinforced the junction and controlled the elevation at which water entered the branch. This water control feature is presently unique among Hohokam irrigation structures; its presence suggests an even greater understanding of hydraulic engineering by the Hohokam than was previously known. In this poster, we summarize the preliminary results of the project and discuss the implications of this new type of water control feature in the prehistoric Southwest.

Village Ecodynamics II South Lithic Research

As part of a long-term study of resource material use in the American Southwest, this research focuses on tool-stone procurement patterns and the morphology of projectile points in the VEP II south study area during the Late Coalition/Early Classic period (A.D. 1275–1400) and Middle/Late Classic periods (A.D. 1400–1540). This research begins by showing the proportion of debitage made of three broad raw material types—obsidian, chert, and basalt—discovered from several sites in the study area. Second, the proportion of obsidian debitage, calculated by these three raw materials, is projected by isopleth maps to identify sites that contain a higher frequency of obsidian during these time periods. Finally, we investigate whether morphological variations of obsidian projectile points recovered in the study area reveal modes of cultural transmission during these time periods.

Late Pleistocene / Early Holocene Human Occupations in Brazil: An Overview and Future Research Directions

In the last decades, the number of well-dated Paleoindian sites and paleoenvironmental studies in Brazilian territory grew considerably. This made possible a real integration between archaeological and paleoenvironmental data, regarding the understanding of occupation and abandonment scenarios, as well the construction of models of site preservation that take into account the response of geomorphic agents. In this paper I will present recent paleoenvironmental data, showing their interplay with the Early Holocene archaeological record in Eastern South America, and suggesting some future research directions.

Tshetshuk, Kamestastin: Interior/Coastal Connections in the Maritime Archaic Period of Québec/Labrador

This paper presents new data on Maritime Archaic occupation at Kamestastin Lake in the barren grounds of Nitassinan (Québec/Labrador peninsula), the heartlands of the Mushuau Innu. Investigations of Maritime Archaic occupation in the Québec/Labrador peninsula have provided evidence of coastal and interior exploitation practices, elaborate burial patterns, diagnostic tool traditions, and social networks intimately tied to the procurement of Ramah chert. While coastal occupation has been a significant focus of Québec/Labrador research over the last five decades, the Maritime Archaic presence in the interior has received much less attention. Ongoing archaeological investigations in the Kamestastin region over the past 15 years have revealed the presence of roughly 260 sites and findspots, including 39 potential Maritime Archaic sites. Several of these early sites are part of complexes connected to important caribou crossing places. Recent excavations at Tshetshuk (GICs-25), an Archaic period habitation site associated with one of these complexes, has produced a number of interesting links to contemporaneous interior and coastal occupations. This paper addresses how this new information can assist in the investigation of the relationship between contemporaneous coastal, interior, and Archaic sites further west, as well as toward better understanding patterns of interior occupation.

Arbuckle, Benjamin (University of North Carolina at Chapel Hill)

Hunting in Near Eastern Prehistory: Status or Subsistence?

Hunting was an important and theatrical socio-political activity in the ancient Near East associated with both elite masculine status and religious practice. Elite hunting expeditions, often memorialized on stone and in song, targeted impressive and dangerous game in which elites visually displayed their control over wild animals in art, clothing, and by stocking animal parks. Wild animals were also given and received as gifts among elites and texts indicate the presence of specialists dealing in wildlife trade. Despite the prominence of elite hunting activities in the art and texts of the Bronze and Iron Ages we have very little understanding of the relationship between status and hunting in earlier periods where hunting is usually labeled as a subsistence activity. In this paper, I explore the relationship between hunting and status in prehistoric Anatolia and ask whether the royal hunts of Bronze Age kings were presaged in the Chalcolithic or even Neolithic periods.

[219]  *Discutindo a origem e o desenvolvimento dos Estados na costa norte andina: cinco mil anos de ocupações no Cerro Ventarron (Lambayeque, Peru)*

Ventarrón situa-se em área de conformação geográfica bastante particular no contexto desértico da costa norte peruana, no estado de Lambayeque. A localidade apresenta grande biodiversidade se comparada a outros contextos áridos da mesma região. Localiza-se entre os vales dos rios Reque e Lambayeque, a 20 quilômetros do Oceano Pacífico e 190 quilômetros da selva baixa, na Amazônia peruana. Está no paralelo seis sul, alinhada ao segundo “paso” mais baixo em direção à porção leste da Cordilherra Andina (cerca de 2200m). Contextos do Formativo Inicial escavados na Huaca Ventarrón apresentaram elementos selváticos que sugerem a interação de sistemas regionais formados pelas ocupações da costa desértica, dos bosques tropicais semi-úmidos e da floresta tropical. Esta comunicação visa divulgar dados de pesquisa recentes que problematizam as fronteiras da “circuscrição” para o contexto de Ventarrón, e contribuir para o debate sobre a origem e o desenvolvimento do Estado andino.

Ardelean, Ciprian (University of Zacatecas, Mexico)
[69]  *Early Hunter-Gatherers and First Human Occupations at the End of the Ice Age and the Early Holocene in the Zacatecas Desert, Mexico*

The field investigations in the northeastern desert of Zacatecas, Mexico (Tropic of Cancer, a region never studied before), revealed an intense hunter-gatherer occupation manifested in 35 new archaeological sites, mainly open campsites. The settlements are situated on paleo-beaches, alluvial fans and heights surrounding an extinct paleo-lake inside an endorheic basin. The research focused on the evaluation of the earliest human occupation there. Preliminary test excavations complemented surface observations. Dunas site yielded interesting flaked stone assemblages on the surface, integrated by tools made of limestone and basalt, probably from the Pleistocene-Holocene Transition or Early Holocene. The rockshelters at San José de las Grutas revealed a new industry of limestone indented based points in an ancient ephemeral camp. Ojo de Agua is rich in extinct megafauna. A proper “black mat” layer was discovered there, for the first time in Mexico, radiocarbon dated for the Younger Dryas cooling episode. The Chiquihuite Cave showed potential old occupation in a still debatable context. The oldest human presence in the area goes back to at least Late Paleoamerican times.

Ardren, Traci (University of Miami)
[194]  *Forest Products and Resource Abundance: Asking the Right Questions about Ancient Maya Trade and Urbanism*

Archaeological studies of ancient Maya trade have long acknowledged the movement of products between different environmental zones as a cornerstone of Classic period economies. One of the most important circulations was between the long coastline of the Yucatan peninsula and the many inland urban centers of the Classic period. In addition to the transportation of long distance trade goods such as obsidian, traders moved savannah products including “phantom artifacts” such as palm thatch and other often over-looked plant fiber technologies essential to household and political economies of the Classic northern lowlands. Chunchucmil, a large urban Classic Maya center, was located in an agriculturally marginal area but adjacent to a rich savannah. Traditional models of agricultural self-sufficiency fail for this particular city which relied instead on trade and exchange. A consideration of the abundance of savannah resources provides a new perspective on initial settlement and eventual urban migrations to this unusual ancient center. Rather than agricultural scarcity, natural resource abundance may be a more
salient characteristic for ancient settlement calculations.

Challenges of Implementing New Praxis: Ethnographic and Community Archaeology in Xaltocan

This talk presents a preliminary ethnographic case study on past and ongoing praxis of archaeology in San Miguel Xaltocan in the State of Mexico. After several decades of ongoing research, archaeologists working at Xaltocan have recently begun to implement community and ethnographic archaeologies, and the community has generally been very receptive to these modes. This past summer, I served as project ethnographer and was embedded in a museum team. The team worked to construct a large exhibit for the community within a large room adjacent the existing museum that the community had designated for the project. The exhibit displays included excavated artifacts and a reconstruction of an adobe house based on archaeological findings from previous excavations in Xaltocan, and was opened to the public in October 2013. My research documented several factors that impeded the full implementation of both community archaeology and ethnographic archaeology in the summer of 2013. This paper examines the ideals of the project before the trip and compares them to the reality that manifested in the field. Furthermore, this essay explores these impeding factors and considers how they could be overcome in the future to allow for a more complete praxis of community and ethnographic archaeology.

Arias, Veronica (University of New Mexico) [268]

Assessing the Feasibility and Efficacy of Data Mining in Current Archaeological Research

One emerging area of GIS development that holds much promise for archaeological research is the application of data mining algorithms to large spatial databases to identify patterns and relationships that are not readily apparent. Although there are few such applications, geographic data mining is particularly well-suited to explore spatial variability across large archaeological datasets and to generate new hypotheses. This paper describes a procedure developed and implemented within a GIS environment to spatially data mine a dataset from the American Southwest. The specific objectives of the study were to explore the feasibility and efficacy of such applications using current technologies and archaeological data standards, identify barriers to its implementation, and demonstrate a new course for GIS-driven innovation in the field. This paper briefly outlines the three-step methodology developed, and discusses the findings both in terms of discovered patterns specific to the study area and broader observations regarding current data practices and technological compatibility. Issues encountered involving data lineage, format, structure, and classification attest to the complexity of geographically data mining archaeological databases with current GIS technology, but also provide valuable insights for the development of future applications.

Arjona, Jamie [213]

Diaspora and Desire: An Examination of Sexuality in Early 20th-Century Jooks

Emerging in the 1880s throughout much of the rural United States, “jook joints” crafted a performatively queer medium within African-American culture. Particularly in the rural south, these jooks offered a haven for black music, dance, gambling, prostitution, and alcohol consumption. The allure of blues and jazz manifesting in jooks would ultimately influence the “cabaret school” of the Harlem Renaissance and the mainstream presence of African-American art forms in the 1920s. Some scholars, such as Nancy Unger, consider the jook a rural point of origin for the more embracing and nurturing urban landscapes that fostered sexual exploration and queer identification. Jooks materialized a queer sense of place that denaturalized identity politics and black “uplift” ideologies (Vogel 2009). While these subaltern venues revitalized fluid performances of sexuality, expectations of whiteness deterred and subjugated diasporic groups. As racist imagery equated black sexuality with the “primitiveness” of African origins, pressures from black elites and intellectuals attempted to excise the jook as a facet of African-American life. This paper discusses how African diaspora in the U.S. was effectively torn between the impossible rubric of whiteness and expressive catharsis of queer performance.

Arksey, Marieka (University of California, Merced), Holley Moyes (University of California, Merced) and Mark Robinson
Las Cuevas is one of the most salient examples of the strong tie that existed between monumental centers and ritual cave sites of the ancient Maya during the Late Classic. The site’s main plaza and Eastern structure lie directly above a large cave set at the base of a sinkhole which has low-lying linear structures around the top and natural terracing ringing the inside. These terraces were initially hypothesized to provide a possible amphitheater-like viewing space for large numbers of people. In order to test this, density analysis of 100 shovel test pits placed throughout the sinkhole revealed not only that approximately 75% of the sinkhole was unmodified, but that there is a distinct pattern of intense use and modification leading down a slope from gaps in the linear structures to the entrance of the cave. Subsequent excavations of select areas on this slope revealed modified natural terraces and constructed steps dating to the Late Classic which demonstrates that the sinkhole during this time period was used almost exclusively as a pathway between the main plazas and the cave and which restricted access to the cave to a select number of individuals rather than providing an open-access, public performance space.

Arkush, Elizabeth (University of Pittsburgh)

Before and after the Middle Horizon at Ayawiri (Titicaca Basin): A Hilltop View of the “Valleys of Ancient States”

In the Titicaca Basin, two periods are associated with evidence for widespread conflict and competition in the absence of pan-regional political integration: the Late Formative (late Early Horizon and early Early Intermediate Period) and the Late Intermediate Period. In the latter period, hill-fort settlements are common and large hill-fort towns are the largest sites of the time. In the earlier period, there is substantial recent evidence for the use of defensive hill-tops as well. Is it appropriate to apply similar interpretations of political fragmentation and social disunity to both periods? How did the inhabitants of defensive settlements in these two eras experience and express group organization at the scales of family, community, and region? Ayawiri (Machu Llaqta) is a highly defensive hilltop site in the western Titicaca Basin with major occupations in both periods. This paper draws on investigations at the site and its surrounding area to characterize social life within and beyond the defensive community. Preliminary results suggest fundamental differences between the two periods in the nature of social group organization, political authority, and regional / interregional interaction.

Armit, Ian (University of Bradford)

Alternative Urbanisms in the European Iron Age: Entremont and Beyond

A recent program of integrated geophysical and topographic survey has revealed new evidence for the organization of space and movement at a number of Iron Age sites in southern France and Sicily. One of the main sites examined was the oppidum of Entremont, near Aix-en-Provence, built around 180 B.C. and generally regarded as the political capital of the indigenous Saluvian confederacy. Entremont also is well known in the archaeological literature for the discovery of a large assemblage of stone statuary including depictions of seated warriors clutching severed human heads. Excavations since 1946 have revealed dense patterns of streets and buildings suggestive of a proto-urban center, but lacking what might be regarded as key elements of urban infrastructure (public open space, large public buildings, etc.). This paper examines the implications of recent geophysical and topographic prospection over the extensive unexcavated areas of the oppidum for the understanding of incipient urbanism at Entremont. It examines the applicability of traditional approaches to early urbanism, such as those of Childe and Weber, and discusses the need for new understandings of how large groups of people come to live together within confined ‘urban-seeming’ spaces.

Armitage, Ruth Ann (Eastern Michigan University)

From Charcoal to Textiles: Archaeological Chemistry Research at Eastern Michigan University

This session recognizes the contributions made by Marvin Rowe to understanding past human activity through radiocarbon dating of rock paintings. During the author’s work with Marvin as his penultimate Ph.D. student, she learned not only how to apply plasma-chemical oxidation to charcoal-pigmented rock paintings, but about the collaborative nature of our research field. This talk will describe the author’s experiences in establishing her own program in archaeological chemistry research, and the influences that Marvin’s mentoring had in shaping that program. Projects in radiocarbon dating rock art and analysis of binding media continue to be the foundation for EMU projects, which now also encompass analysis of museum objects, residues, and even textiles and dyes. Marvin’s unique emphasis on the highest standards in analytical chemistry combined with a desire to work directly with archaeologists to answer questions about ancient materials have influenced not just the author, but the many undergraduate and
graduate students and collaborators with whom she has worked since.

Armour, Daryl [327] see Boudreaux, Edmond

Arnauld, Charlotte (CNRS)

The simultaneous elucidation of “mobility” as a normal circulation of individuals or groups among Maya cities, and of the “migrations” that apparently took place during the Terminal Classic across the Maya Lowlands is key to our understanding of the transition (collapse or crisis) from Classic to Postclassic times. Beyond precisely dating the abandonments of urban settlements, we need to establish whether they did result from massive, and rapid population movements, or from a gradual drifting out. How might regular mobility related to social and economic practices during Classic times help in predicting posterior, larger movements? Evaluating (in rhythm and size) the development of residential masonry architecture within urban neighborhoods allows the archaeologist to outline specific social dynamics over time that encompassed immigration and emigration of households. Case studies from Río Bec (Mexico) and La Joyanca (Guatemala) are presented to illustrate and contextualize a mobility process that seems to have paved the way for non-massive, gradual abandonments of urban neighborhoods under specific circumstances.

[124] Regional Mobility of Domestic Herds and Their Implication for Understanding Land Use in the Early Iron Age of Southeastern Africa

This research seeks to identity exchanges of cattle during the Early Iron Age (EIA, i.e. 1st millennium AD) of southeastern Africa to examine elements of the Central Cattle Pattern (CCP), settlement hierarchy and land use. The CCP is an archaeological model of spatial organization to explain the nature of Iron Age communities. The presence of this pattern would demonstrate an EIA society characterized by hierarchical social relations controlling land use and livestock resources. Previous research in the Thukela River valley utilized zooarchaeology, stable isotope, and phytolith analyses to examine this model. Importantly, several cattle were identified through the strontium isotope analysis as having come from outside the Thukela Valley and indicate a regional pattern of land use as well as social, economic, and/or political connections throughout the region developing in the later phases of the EIA. This paper presents additional data from EIA sites in the nearby Mgeni Valley that suggests connections and cattle exchanges between these two areas. This movement of cattle between regions may be suggested as a major means to power and results in increased societal complexity, inequality in access to resources and the rise of chiefdoms.

Arnold, Dean (Field Museum)
[281] Ethnoarchaeology and the Meaning of Style: An Example from Quinua, Peru

The separation of style and function in archaeology is almost a sacred distinction in archaeology and seems fundamental to the discipline. Style, of course, has multiple functions, and many stylistic analyses crosscut vessel shapes with different uses or functions. This paper briefly explores four different types of stylistic analyses (design structure, symmetry, design motifs, and explicit meaning) of multiple ethnographic vessels of one shape in Quinua, Peru. These data suggest that different kinds of meaning can be derived from each approach, and indicate that non-referential, abstract, and non-realistic designs can reveal social meaning when coupled with vessel function.

[270] Superstorm Sandy’s Halloween Surprise: Initial Inventory and Assessment of Colonial-Era Burials from the New Haven Green

On October 29, 2012, Superstorm Sandy devastated much of America’s East Coast. In Connecticut, high winds toppled the Lincoln Oak, a large tree planted in 1909 on the New Haven Green. Within exposed roots, a partial human skeleton was visible. This treefall provided a unique opportunity to study a Colonial era cemetery. Here, we present a review of the six burials recovered from the Lincoln Oak rootball. We combine analyses from osteology, isotopes, genetics, and radiology. Several individuals show skeletal or dental pathologies illuminating health and disease in New Haven prior to 1821. Associated artifacts such as coffin tacks and personal effects provide information about mortuary practices and potential context. The biological and archaeological evidence are placed into a larger context based on Colonial demographic and mortuary data. Our multidisciplinary approach combines the expertise of municipal historians and academic researchers, and demonstrates how coordinated efforts yield more meaningful results than any single line of inquiry. We suggest applying this approach when any human skeletal material or archaeological sites are exposed. This research was supported by the Committee of the Proprietors of Common and Undivided Lands at New Haven, the Yale University Department of Anthropology, and the New Haven Museum.

[279] The City over the City: Kaminaljuyu and Urbanism

Kaminaljuyu is an important Mesoamerican center that has been studied in pieces due to the fact that it lies underneath modern Guatemala City. However, various projects have contributed to the understanding of its origins and development. This paper makes an attempt to evaluate various questions such as the presence of urbanism, the point in time at which urbanism developed, social factors that had implications for the presence of urbanism, and the influences by other regions and sites that impacted such development. New data from recent research will be presented to understand Kaminaljuyu’s development during the Preclassic and Classic periods.

[248] Winter Wonderland and Canadian Shield Rock Art

The logistics of studying Canadian Shield rock art dictate that this form of visual expression is most often studied during the summer time. A winter study of rock art sites has seldom been undertaken, though it presents alternate possibilities for recording, as well as for the interpretation of these images and the analysis of some aspects of its long-term preservation. Through a series of examples taken mostly from Quebec’s sites, this paper will attempt to present new venues for the recording, conservation and interpretation of Canadian Shield rock art sites, as well as shed light on the seasonal possibilities of creation and occupation of these sites.

[127] “Ravens that Fed Elijah Cry to Us: ‘Leave the Ploughs!’” (Isaac of Antioch): Rural Monasticism in Late Antique Levant—Literary and Archaeological Reflections
The haranguing words of Isaac of Antioch, criticizing the coenobitic monks, who spent their time plowing their lands, planting their orchards and negotiating with lay people while renouncing their duties as “Holy Men,” reflect the change that overtook the monastic movement towards the end of the fourth century. Monasticism, to the growing concern of monastic fathers such as Isaac of Antioch, became constitutionalized and ecclesiastical, stepping far from the ideal anchoritic manifestation, propagated by hagiographic literature. Looking at the rural landscape of late antique Levant, thousands of monasteries dotted the countryside of the region, spreading from the limestone massif of North West Syria, through Phoenicia and Palestine to the fertile soil along the river Nile in Egypt. All these monasteries were inhabited by monks that were part and parcel of the rural society, joining hands with their village neighbors, in everyday labor. In this paper we will try to trace, through archaeological surveys and excavation conducted in the Levant, the departure point from which the anchoritic Holy man took off from the deserted hermitage to become a prominent social and economic factor in rural society and to understand the causes for this transformation of monastic manifestation.

[208] Individual Variation in Flake Scar Patterns on Experimental Projectile Points

The idea that flake scar patterns on projectile points might be used to identify the work of individual flintknappers in archaeological contexts dates back to at least the 1970s (Gunn 1977; Whittaker 1987). Individual-scale analyses are a promising approach to a better understanding of a variety of topics in archaeology, but methods proposed for identifying the handiwork of individuals must be rigorously tested. Techniques for documenting and comparing flake scar patterns, relying primarily on image analysis, have improved in recent years (Watts 2013). An experimental project was undertaken with modern flintknappers to assess the reliability of flake scar measurements as data for recognizing a craftsman’s unique signature. A relatively large number of small triangular projectile points (over one hundred) were collected from modern knappers and analyzed. Two primary questions were the focus of the research. First, how reliably do flake scar measurements, as previously documented by Watts (2013), differentiate the work of modern craftsmen? Second, can the experimental data be used to develop better statistical methods for identifying the work of individuals?

Ashley, Keith (University of North Florida)

[213] Moving to where the River Meets the Sea: Origins of the Mill Cove Complex

The post-Archaic Native history of northeastern Florida has long been interpreted as continuous series of insular cultural developments interrupted only by European arrival in the late sixteenth century. Recent studies, however, are presenting a more dynamic landscape in which groups moved into and out of the region at key points in time, altering the historical trajectory of the region. With a grounding in historical process and interregional interaction, this paper proposes that the Mill Cove Complex was established by immigrant St. Johns groups who sought entry into Early Mississippian (A.D. 900-1250) exchange networks.

[244] The Codifi Data Management System for the Barrow Island Archaeology Project (BIAP)

At 7am in BIAP Camp on any fieldwork day, the historic, excavation and survey teams meet for logistics before splitting up to explore and document the immense archaeological record that is Barrow Island. Working around an active oil field and without access to cellular technology or power, the three teams embark each day to collect an astonishing array of high definition images, video, geo-coordinates, notes, and archaeological data forms. All told, each season will yield hundreds of thousands of individual data records totaling in the terabytes that must be securely preserved and managed from morning pre-check to end-of-day backup through post-season analysis, archiving and publication.

As ambitious as this may sound, the real challenges are not only technical. The goal is to develop a unified methodology for BIAP, harnessing the expertise of the diverse team without limiting creativity or tried-and-true practices to a single “way” of digitally doing fieldwork. We’ll look under the hood at the Codifi data model and how we’re together building a system that fosters best practices in digital data management while encouraging conversations through real-time sync and revolutionary “born archival” workflows.

[249] Obsidian Technologies in the Near-East
Obsidian studies in the Near-East rely on integrated approaches including detailed analysis of the geological complexity of volcanic massifs, geographical distribution of sources, archaeometric signatures of the glasses and studies of the production and use of archaeological artifacts. Recent developments focused notably on the techniques employed to detach blanks and on the use and curation of tools. These methods allow us to reach different levels of interpretation. Our aim here is to illustrate, with the help of several examples, ways in which they can throw light on the socio-economic contexts of diffusion and use of obsidian, the function of sites and the evolution of technical traditions.

[162] The King and the Lion and the King as Lion in Assyrian Representations of the Royal Hunt
Representations of the royal hunt in Assyria have often been interpreted as expressing the supremacy of order over chaos or that of civilization over wilderness. Such polarization, however, leaves unexplained the formulaic statement that the Assyrian king makes in royal inscriptions, "I am a lion and I am a (potent) male," equating himself with what he defeats. Instead of the king's literal superiority to the lion, the paper focuses on an alter-ego relation between the two. It argues that in the hunt, rather than an external enemy, the king targets, metaphorically, an aspect of himself, or his self, in a sacrificial act that results in his new formulation as the supreme priest-king. Proposing an analogy to the Mitra-Varuna dichotomy in Indo-Iranian mythology, the paper reinterprets the antagonistic relationship between the king and the lion as the transformation of the "enemy" (Varuna) into the "friend" (Mitra), and hence as the annihilation of a domineering warlike ethos in the process of the making of a perfect man. Such complexity challenges the long-established paradigms of power and virility, so far construed primarily as superiority over outside opponents and sexual prowess, in viewing the royal persona in the study of the ancient Near East.

[316] The Ecology of Coastal Foraging by Native Californians in the Ten Mile Dunes
Why did native Californians leave shell middens in dunes some distance from their collection site, when ostensibly better settlement locations existed closer to the collection site? We apply optimal foraging theory to archaeological data from the Ten Mile Dunes to reconstruct prehistoric behavior. Using data acquired in excavations during the UCD Field School 2012, we model a native Californian coastal diet and explore foraging behavior and its implications. We find that diet breadth models predict an optimal diet consisting of a singular item, Cryptochiton stelleri; however the data imply a more diverse diet. Additionally, the high frequencies of Mytilus californianus and Balanus nubilus found in the shell middens suggest that either these were the only components of the diet or that other resources were field processed, which is inconsistent with the field processing models’ predictions that transporting unprocessed loads is more economical. When we impose the time constraint of daylight in the models, transport load size decreases, and most resources are predicted to be field processed. This is more consistent with the observed excavated materials, suggesting that time was indeed a constraint for coastal shellfish foragers, contrary to classic field processing models’ assumptions.
Atwood, Kirsten

Iron Age Cuisine at Bosutswe, Botswana: Food and Inequality

This paper addresses the animal-based portion of the diet at the Iron Age site of Bosutswe, Botswana. I argue that the Western (commoner) inhabitants consumed more wild game than Central (elite) inhabitants during most occupation phases. While the Central inhabitants did consume wild animals, they seem to have focused more on the “special” or spiritual animals, and on large animals that required group hunting. The Western inhabitants focused on the dietary aspects of wild game, but also seem to reject a monopoly on spiritual power by the Center, practicing some ethnographically documented ritual traditions longer than the Center people, and adopting new traditions (big game hunting) later than inhabitants of the Central Precinct. Despite the differences in what was eaten, how meat was cooked appears to be similar amongst both commoners and elites. Meat appears to have largely been boiled, as much meat is in Botswana today. I link the extreme difference in cattle culling patterns between the elite and commoner areas of Bosutswe during the Early and Middle Loose, in which the elites preferentially consumed juvenile and aged animals, to the current preference for “chewy” meat in Botswana, and processes of social emulation.

Aubert, Deanna (McMaster University)

Curating "Canadian-ness"

The government of Canada has recently initiated changes that affect Canadian archaeological practices and funding to heritage institutions, including cuts to Parks Canada, a renaming of the Canadian Museum of Civilization (to the Canadian Museum of History), and a revamping of the Department of Canadian Heritage programs. These initiatives call for an inquiry into the relationship between Canadian archaeology, national identity, and political agendas. This presentation examines these themes through an analysis of curatorial practices in Canadian museums, more specifically the decision making involved in what stories are told, how these pasts are represented in text, object and image, and how these practices serve to shape public perceptions of ‘Canada’ and its past.

Developing Mobile-Based Digital Forms for Archaeological Data Collection

This research discusses how to create data collection software on mobile devices and tablets to maximize data quality in the field. This paper demonstrates the processes used to develop OsteoSurvey, a set of forms designed to collect bioarchaeological data on human remains in the field utilizing Open Data Kit (opendatakit.org). During the 2012 and 2013 field seasons at Deir el-Medina, Egypt, osteologists recorded over 600 entries and 30,000 observations on an Android-based tablet utilizing OsteoSurvey. When tested against traditional paper forms, the OsteoSurvey not only saved time in data collection, but actually increased the consistency of the data being recorded in the field through decreasing interobserver variability and ensuring all entries are fully recorded. This research further addresses other digital data collection platforms such as Ohmage and how to integrate digital data collection with Open Context and other web-based data collection publishers. Finally, this paper evaluates the advantages and disadvantages to digitizing data collection, and suggests best practices for creating and disseminating data sets. This is particularly useful for archaeologists conducting survey work, as mobile data collection can not only automatically record timestamps and GPS coordinates, but can also be uploaded immediately to a shared server.

Aviam, Mordechai (institute for galilean archaeology, Kinneret College)

First Century Galilean Entrepreneurs

It is a common approach that Jewish Galilee in the first century was built of urban rich society, concentrated in the two Galilean capitals Sephoris and Tiberias, and large rural society in the Galilean villages which was considered "poor" and their habitants sometimes even called "peasants." During the last 15-10 years, archaeological excavations uncovered the remains of 1st century residential areas at Yodefat (Jotapata), Migdal (Magdala) in the Galilee, and Gamala in the Golan. From the finds, it is very clear that not all Galilean villages were poor… and that there was wealth even in small Galilean sites, or in other words, there were rich and poor people in cities, towns and villages. This paper will focus on
finds from Yodefat such as an unusual amount of loom-weights, large amount of sheep bones, all point to the manufacturing of wool materials. The discovery of four pottery kilns at the site, prove the existence of pottery production at this mountainous town. I suggest that the Galileans, since the time of the Hasmonaean dynasty and up to the First Jewish Revolt were entrepreneurs and succeeded in building strong rural economy even though sometimes the land was poor, rocky, and covered with thick vegetation.

[174] The Pigment Recipe: Understanding Rock Art Production at Vasquez Rocks
Given that prehistoric peoples are believed to have targeted specific mineral sources for the production of pictographs, the connections between rock art panels and their material sources are not clearly represented in the archaeological record. Drawing on the basic understanding of rock art production, this study looks further into analyzing the selection of material for the production of pictographs in Southern California. What can the selection of specific material in the landscape clarify about the artist and the painting depicted? Can such a study clarify the level of significance, in the rock art, as a result? Located at the center of major tribal areas of southern California, an analysis of the rock art at Vasquez Rocks can well help understand these questions, along with the mental process of the craftsmen and the level of interaction amongst neighboring groups.

[31] Of Apples and Oranges: A Comparison of the Early Middle Preclassic Maya of the Belize River Valley and Their Contemporaries in Northern Belize
Between the 1970s and 1980s, investigations at Cuello and Colha established the presence of early Middle Preclassic Maya settlements in northern Belize. A decade later, archaeological research at Cahal Pech and Blackman Eddy identified coeval settlements in the Belize River Valley. Together, the data produced by these investigations have shed important information on the genesis of Maya civilization and the rise of cultural complexity in the Maya lowlands. In spite of these contributions, however, few archaeologists have attempted to understand the relationship between these precocious communities. This paper compares the material culture of the early settlements in northern and western Belize and examines whether the evidence warrants placing the two sub-regions in a similar cultural sphere.

[121] Imperial and Local Pottery in the Chinchaysuyo: Examining Provincial Economy through Ceramic Distribution and Consumption Patterns in the South Central Coast, Perú
Research on empires has mainly focused on the processes of imperial conquest and the consolidation of societies close to the imperial core. More recently, studies have recognized the value of examining processes of imperial control over non-state societies located far from the core to better understand the variety and flexibility of strategies involved in the incorporation of conquered groups. Empires, whether modern or ancient, transform non-state societies to suit their needs. Like many other expanding states, the Incas (A.D. 1400-1532) developed a variety of strategies to satisfy their demands for tribute from the myriad societies that came under their influence. Using a multidisciplinary approach, this presentation builds upon recent research in the Asia Valley, a marginal region on the south central Peruvian coast. Building on elemental composition analysis of clays and ceramics from the Asia, Mala, Lurín and Chincha Valleys, I examine the patterns of distribution and consumption of Inca and local ceramics in the south central Coast. Studying ceramic consumption and distribution in the south central Coast provides an important avenue to explore the different ways that coastal groups interacted with the empire and complied with their policies.

[103] An Unusual Late Middle Sicán Sacrifice, Peru: An Osteobiographical Analysis
During the Sicán Archaeological Project's 2008 field season, excavation atop the North Platform of the Huaca Loro temple mound revealed the skeletal remains of an adult, possibly male, who was interred with arms wrapped and tied around an algarrobo (Prosopis pallida) wood post. This mortuary context suggests that the individual may have been sacrificed. Additionally, osteological analysis revealed evidence of possible trauma and infectious disease. Given that the individual is part of a particularly well-contextualized archaeological sample and exhibits a range of pathologies, this individual presents an excellent case for osteobiographical analysis. Osteobiographies reconstruct the life history of a specific individual based on skeletal evidence, providing a bottom-up method of understanding daily life within archaeological populations. The contextual knowledge about the Sicán culture creates a backdrop for the in-depth social and biological analysis of this sacrificed individual. By comparing the life history of this individual to other spatially and/or temporally related interments within the same and nearby temple mound complexes, this poster suggests factors which may have socially marked this individual for sacrificial treatment. The results will incorporate both mortuary and osteological evidence in an interdisciplinary analysis, demonstrating the value of osteobiographical research to archaeological investigations of past populations.

[144] Domestic Architecture of the Casas Grandes Western Periphery in Context
Although Charles DiPeso studied the architecture of Paquime in depth, domestic architectural patterns of the Casas Grandes region as a whole are poorly understood. This paper discusses recent observations of the domestic architecture of the Western periphery from the Viejo and Medio Periods and places these patterns into regional context. In addition, attributes sensitive to regional variation including construction technique, room shape, doorway shape, and hearth shape are discussed in detail.
Reconsidering Landscapes: New Discoveries at Cahokia

Cahokia Mounds (A.D. 1050-1300), located in the American Bottom of southwestern Illinois, is a large monumental city with organized neighborhoods, plazas, and earthen monuments. The layout of the site has previously been discussed as oriented to the cardinal directions with large 'marker mounds' delimiting site edges. Based on new research on two ridge-top mortuary mounds located on Cahokia's edges and new evidence for the existence of a central, raised earthen causeway, this poster will reconsider the original assumptions regarding site orientation and landscape use. The addition of a central elevated causeway that until now was never corroborated archaeologically is an important factor in understanding how Cahokians used and transformed their surroundings. This foundational and important causeway, in addition to the newly gathered information on ridge-top mound construction and use, presents a unique picture of early Cahokia, one aligned to mortuary space, the cosmos and possibly even religion.

As They Died, So They Were Buried? A Mortuary Study of Tiwanaku Social Differentiation at the Omo M10 site, Moquegua, Peru

As complex social contexts, human burials can convey information about individual life histories, social identities, ritual practices, and larger social organization. Over the past decade mortuary and bioarchaeology have made significant contributions to the study of the Tiwanaku polity, one of the earliest states to emerge in the south central Andes (A.D.500-1000). Recent excavations and ongoing analyses of over 200 burials from the Omo M10 site (Moquegua, Peru) – a regional Tiwanaku ceremonial center – have produced a large body of data that elucidates patterns of site-wide social differentiation. What role did mortuary rituals play in asserting and contesting identities and differences in provincial Tiwanaku society? Did distinct social groups maintain different funerary practices? If so, what were the implications? This paper employs multivariate analyses to compare burial contexts across discrete spatial divisions in the mortuary landscape in terms of body preparation and deposition, as well as grave offerings such as ceramic vessels, textiles and foodstuffs. In addition, we consider bioarchaeological indicators relating to the deaths of the interred to explain the diversity of mortuary practices at the site, as they played a role in the social and ritual life of the Tiwanaku colonists in Moquegua.

Architecture: Structural Preservation in Northwestern New Mexico and the Need for Funding

The San Juan County Museum Association is a non-profit organization that manages Salmon Ruins, an 11th century pueblo, near Bloomfield, New Mexico. The Association has been involved in the preservation of the prehistoric, Chacoan community for forty-five years. Its broader mission of site stewardship and preservation has extended to numerous heritage sites around the greater Four Corners Region. Back-country archaeological sites remain important in terms of research, education and heritage tourism. Support by agencies and the general public needs to be solicited for "brick and mortar" funds to preserve architecture. This need is critical if we are going to preserve standing structures and avoid leaving only remnant rubble for future generations to study and interpret. Consequently, ruins stabilization programs will, by their nature, continue to advance public interest and advocacy for long-term preservation of our national heritage. Examples of preservation projects and stewardship programs are detailed in this context.

Enigmatic Pecked Features on Ometepe Island, Nicaragua

During the course of a 10-season archaeological survey on Ometepe Island, Nicaragua, basalt boulders
have been found with enigmatic pecked features that are surprisingly standardized with regard to size and shape. In several sites they are the predominant features. Although these are usually found associated with petroglyph boulders, they are not what are normally thought of as petroglyphs. We believe that these are a type of specialized quarry stone from which elongated, rectangular, bar-shaped pieces of rock have been removed. It is thus far unclear what use may have been made of the removed stone, whether as a tool or other type of artifact, or whether they are of utilitarian or ritual significance. Despite an extensive search in the available literature, no references to this type of feature have thus far been found.

[61]  Ichkabal. Un asentamiento del Preclasico Medio. Primeras investigaciones
El sitio de Ichkabal se localiza a cuarenta kilómetros al poniente del municipio de Bacalar en Quintana Roo y a nueve kilómetros al noreste del sitio de Dzibanche. El asentamiento se ubica en medio de tierras fertiles, rodeadas de depresiones inundables (bajos) y abundantes aguadas. Es un sitio de monumentalidad excepcional, producto de una sociedad compleja cuyos inicios datan del periodo Preclásico Medio (500 a.C.). Su acceso, se efectua tomando la carretera de Bacalar, a 19.5 kilómetros por la carretera de asfalto, al poblado de Reforma, hasta llegar al Rancho El Suspiro, posteriormente se recorren veinte kilómetros mas, por el camino de terracería, hasta llegar al area monumental.
A juzgar por los recorridos de superficie realizados en el area , el patrón de asentamiento es del tipo "desarticulado", similar al de Dzibanche; argumento que obliga al estudio de unidades de analisis, de cada una de los grupos arquitectónicos que la integran (Ciudad de las Moras, El Ramonal [Templo de las Higuera], Mario Ancona, Los Lirios, El Zapotal, entre otros). Esta investigación implica una estrategia urgente en la protección y conservación del patrimonio arqueológico, compatible con la conformación de un Parque Eco-arqueológico.

[61]  Genesis Maya: How the Work in the Mirador Region Reshaped the Course of Preclassic Maya Research
Intensive investigations in the Mirador Basin of northern Guatemala were among the first to recognize the extent and range of the social, political and economic complexity of the Preclassic Maya. The work, conducted over nearly 35 years, has revealed new information relevant to the socio-political sophistication that transformed Maya studies in subsequent decades. This paper will define the roles and impact of these investigations.

Balco, William (University of Wisconsin-Milwaukee)
[89]  Mead, Wine, Power, Prestige: Commensality and Change in Late Iron Age Western Sicily
As Greek and Phoenician populations spread throughout the central and western Mediterranean, they introduced new lifeways to neighboring, extant indigenous populations. One cultural feature adopted in whole or in part by indigenous populations was the Greek symposium, a feasting ritual involving the social consumption of wine. This paper employs a postcolonial approach to examine the shift from consuming fermented grain beverages to drinking wine among indigenous western Sicilian populations during the seventh to fourth centuries B.C. Material culture responses are discussed, exploring the archaeologically visible remains of the transformed feast in order to better understand why Greek-style commensal behavior was so appealing to indigenous Sicilian populations. Results suggest that local populations may have emulated their impression of the Greek feast as a form of conspicuous consumption demonstrating social prestige within the local community.

[210]  The Technological Organization of Desert Hunter-Gatherers during the Middle-Late Archaic Transition in the American Southwest

Large-scale excavations at Luke Air Force Base near Phoenix, Arizona resulted in the collection of approximately 60 Middle to Late Archaic projectile points and fragments. Most of the intact bifaces fit the criteria for Chiricahua and San Pedro type points, technologies that are typical of these periods in the Sonoran Desert. The Luke collection is unique because few sites preserve the Middle-Late Archaic transition in a stratified and dated open air context. Still more, it samples an unanticipated technological landscape of dedicated high-tech biface manufacture (total weight 6.5 kg) contrasted by large, shaped ground stone tools (total weight 3528 kg) that were transported to the site at considerable expense. These stereotypically male and female technologies transcend the appearance of maize elsewhere in the Southwest, but there is no convincing evidence that maize was cultivated or consumed at the site. Previous studies identify a dramatic reduction in mobility during the Late Archaic period, when evidence for semi-permanent riverine agricultural village life appears in the region. Using routine measures of technological organization, this poster presents the evidence for continuity in residentially mobile hunter-gatherer lifeways and subsistence during and after the transition to agriculture.

Baltus, Melissa (University of Illinois Urbana-Champaign)
[205]  Daily Choices, Historical Changes: Revitalization of Thirteenth-Century Cahokia

The rise and eventual decline of Cahokia, the largest pre-Columbian city north of Mexico, reverberated deeply within the historical trajectories of the North American mid-continent and southeast. The 11th century emergence of this multi-ethnic, multi-vocal metropolis appears to have been deeply entangled within a social-religious movement that spread rapidly throughout the region. Within a few generations, however, that initial movement became highly politicized, coupled with the spread of violence throughout these same areas. Archaeological evidence from two late-twelfth to early-thirteenth century villages in the uplands outside of Cahokia exhibits the choices and changes people made in their daily lives during and following this period of violence served to distance themselves from the more highly politicized (traditional Cahokian) “elite” spaces and objects. At the same time, people maintained and/or re-integrated practices, objects, and buildings reminiscent of the early Cahokian movement. These two sites, nearly contemporaneous with each other, demonstrate clearly different practices and relationships, indicating that people at these sites were maintaining a certain amount of autonomy while still participating within the revitalized Cahokian landscape.

Bamforth, Douglas
[246]  Learning Archaeology from Mike Jochim

This paper introduces a session honoring Michael Jochim’s career in archaeology on the occasion of his retirement. I emphasize three major topics. First, Mike was one of the first archaeologists to bring optimization theory into our field, most notably into hunter-gatherer archaeology, and I consider both his contributions to this domain of thought and its role in his personal research program. Second, Mike is a superbly creative and technically rigorous archaeologist. His decades-long program of field research in southwestern Germany is a model of what it takes to turn even the most theoretically sophisticated ideas into empirically-supported knowledge of ancient people, and I emphasize the importance of this. Finally, and more personally, for over 30 years Mike has been a mentor and role model to students and...
colleagues, many of whom are in this session. I close my discussion, and underscore the diversity of papers to follow, by acknowledging that.

Banning, Edward (University of Toronto) and Isaac Ullah (University of Pittsburgh) [335] In Small Things Miscounted: Problems, Solutions, and Opportunities of Scale in Microrefuse Analysis
Archaeologists can learn much about the distribution of cultural evidence at various scales ranging from trade over large regions to intercommunity relations over smaller ones, daily interaction within communities, and down to activity in individual households. One could argue that in many types of societies a significant proportion of the human experience takes place within and around houses, which is why houses play such a prominent role in discussions of habitus. Yet there are considerable challenges in the attempt to unravel this habitus, especially when many of the macroremains pertain to short-term activities that may not even be typical. By contrast, focusing on the tiniest debris that accumulates over long periods may help us overcome these challenges. However, many archaeologists have been reluctant to employ microrefuse analysis because of the erroneous perception that the scale of effort involved must be astronomical. We contend that careful consideration of the spatial and analytical scale of sampling factors permits us to detect robust patterns that probably reflect the distribution of persistent activities over longer time scales with a small fraction of the effort that previous analysts have employed.

Barber, Sarah [8] see Menchaca, Victoria

Barber, Michael, Carole Nash (James Maidson University) and Michael Madden (USDA-Forest Service) [152] The "Public" in Public Archaeology: Down from the Ivory Tower and into the Real Trenches
Archaeology is not for the benefit of the archaeologist. Building on the foundation of the Archaeological Society of Virginia, Virginia's community of professional archaeologists has joined forces with the ASV and other partners and developed the "Certification Program for Archaeological Technicians." The program trains avocational archaeologists in the theoretical and methodological underpinnings of the profession. It is our contention that co-creation should begin with the first phases of any archaeological endeavor and continue through interpretation and overall historic preservation.

Barber, Sarah (University of Central Florida) [191] Peripheries and Crossroads: Shifting Boundaries and Identities on the Mar del Sur
The Pacific coast of Mesoamerica was a politically and economically dynamic area throughout the pre columbian era. Ethnohistoric records indicate that during the Late Postclassic period alone the region was pivotal to long-distance exchange networks, was conquered multiple times by inland groups, and was the site of large-scale population relocations. The southern Pacific coast was thus a melange of intersecting ethnic and linguistic groups derived from millennia of social interaction at porous social boundaries. Drawing on case studies from Oaxaca's central and western Pacific coastal zone, this paper considers how people in a highly dynamic social environment developed, maintained, and modified local and macro-regional social ties. Situated at boundaries between the Mixtec and Zapotec to the north and west, and Mixe-Zoque and Maya speakers to the south and east, the inhabitants of Oaxaca's coast defined distinct local identities in the face of (at times) significant external pressures but also showed flexibility and malleability in periods of major political and economic change. Variation in iconography, technology, and settlement from the Protoclassic to the Late Postclassic periods in the Manialtepec Basin and lower Río Verde valley suggest that, as political centers of gravity changed, so too did local

[59]  
Evaluating Food, Identity, and Moche Valley Society through Archaeobotany

This paper examines social, political, and economic transitions witnessed prior to and following the expansion of the Moche political economy ca. A.D. 300 through the lens of domestic foodways. Foodways represent a fundamental axis along which identity is constructed and maintained, and are increasingly recognized as having played a prominent role in the emergence of social hierarchies and the negotiation of status and power. Indeed, advances in Andean scholarship have elevated culinary concerns beyond the realm of the domestic, which is often considered to be outside the domain of the active and political, in works focusing on the significance of plant remains for tracking sociopolitical change and social memory; the powers women exercise as purveyors of culinary/agricultural knowledge; and the centrality of the kitchen in modern Andean contexts. Despite these advances, there remains a dearth of systematic analyses of archaeological plant food remains on the Peruvian north coast. I discuss recent paleoethnobotanical research from the Moche and Chicama Valleys, synthesizing available data to illuminate various subsistence strategies that profoundly shaped Moche sociopolitical development. I consider how plant data can be used to evaluate different social and spatial contexts, and conclude with directions for future research.

Corrugated Pottery and Communities of Practice

Often within archaeology, the study of social identity and cultural practice through ceramics has focused on analysis of decorated pottery. There is good reason for this; decorated ceramics represent a higher time investment than utility wares and the decorations on ceramics are often considered to be iconographic signs that encode the values of the society in question. However, the value of studying utility wares in order to explore social identity and cultural practices is often overlooked. Through a consideration of utilitarian corrugated pottery in the prehistoric U.S. Southwest this research explores the relationship between social identity, artifact style, and communities of practice. This research compares the physical attributes of Homol’ovi utility wares, locally produced within the Homol’ovi site cluster in northeastern Arizona to those of utility wares produced in the Tusayan area, specifically Tusayan Gray Ware and Awatovi Yellow Ware. The primary goal of this study is to explore the presence, extent, and significance of standardization in manufacturing methods within these two production areas in order to better understand community composition and organization within the Homol’ovi site cluster.

That Work/Life Thing...

Despite the current emphasis on “work/life balance” in university settings and a wealth of positive messages in policy statements, the graduate school experience for many women archaeologists presents tremendous difficulties when pregnancy, birth, and childcare are thrown into the mix with an active and ambitious scholarly agenda. How can the oft-resulting “gap” in fieldwork, research, and progress toward the degree (and career) be mitigated? In this paper we explore these difficulties, our efforts to eliminate them, and the successes and failures of our attempts at solutions.

Features of Household-Level Flaked-Stone Production at the Neolithic Site of ‘Ain Ghazal, Jordan

Over the past two decades, there has been significant progress in research focused on the identification, characterization, and socioeconomic implications of specialized flaked-stone industries of the southern Levantine Neolithic. Few studies, however, consider in detail the nature and scope of nonspecialized
household-level flaked-stone production at sites with specialized production, or what this can add to the understanding of social and economic relations on the site level. To that end, the research presented here considers several features of flaked-stone production from domestic-related contexts, including a sample of debitage, tools, and cores, from the Neolithic site of ‘Ain Ghazal, Jordan, with the goal of gaining insight into some of the social and economic interactions that occurred over the course of occupation.

[321] From the Inside: Paste Variation in Mogollon-Mimbres Ceramics from Woodrow Ruin in the Upper Gila, New Mexico
Woodrow Ruin (LA 2454) is the largest Mimbres site in the Upper Gila valley in New Mexico. The site was occupied from the Late Pithouse period through the Classic period, approximately A.D. 550 to 1150. Recent excavations in a large, subterranean communal structure yielded the full sequence of Mimbres pottery types from Alma Plain to Mimbres Style III. A preliminary study was conducted on a sample of the ceramics from the communal structure to explore the variation in the paste and temper of the ceramics. Macroscopic examination and refining analyses were used to examine the paste and temper in both utility ware and decorated ceramics. This preliminary study provided the opportunity to explore the paste and temper variation within and between Mimbres pottery types in the Upper Gila region.

Barnard, Hans (Cotsen Institute of Archaeology at UCLA), Augusto Cardona Rosas (Centro de Investigaciones Arqueologicas de Arequip) and Maria Lozada (University of Chicago)
Between 2008 and 2013 an archaeological research project by the University of Chicago and UCLA, in cooperation with the Centro de Investigaciones Arqueologicas de Arequipa (Peru), investigated the Millo settlement complex in the Vitor Valley, just west of the modern city of Arequipa in southern Peru. Archaeological excavation of residential structures as well as graves yielded a pottery assemblage composed of small amounts of locally made imitation Wari- and Tiwanaku-style vessels among many vessels associated with the Ramada culture (Siguas III). Radiocarbon analysis of associated finds dated the pottery to 850-900 CE, which confirmed earlier thermoluminescence dates of similar vessels (Cano et al. 2009). The large amount of excavated sherds in combination with several whole vessels facilitate new research into the Ramada ceramic tradition, including petrologic thin-sections and organic residue analysis.

[30] Remembering Camp Monticello: Archaeology of a World War II Italian Prisoner of War Camp
Camp Monticello, the Italian Prisoner of War (POW) camp located in Monticello, Arkansas, is a significant part of Arkansas’s World War II Home Front heritage. The camp opened as a training facility for the Women’s Army Auxiliary Corps (WAAC) in 1943 and served as a POW camp for Italians from 1943 to 1946. Today, the camp consists of stone foundations that once comprised three compounds that housed enlisted men, two compounds that held officers, a hospital and other facilities. Archaeological research at the camp and the artifacts used and produced by those interned provides important counterpoints to the documentary and oral historical records. The research, which actively engages the public, challenges and reworks narratives and memories of life at Camp Monticello and yields new information about Arkansas's role in World War II, the lives of women at the camp, and the ways in which the Italian POWs adapted to confinement and expressed ethnic and cultural identity through daily practice.

[322] Photogrammetry or 3D scanning? Aerial Photogrammetry or Airborne Lidar?
Laser scanning has become increasingly popular within archaeology and related disciplines over the last decade for a variety of reasons including their speed, accuracy, and precision in producing 3D models of artifacts, architecture, and sites. One major disadvantage of 3D object scanners, terrestrial laser scanners, and airborne lidar are their cost. The question inevitably arises: Can a decent camera and
good photogrammetric software take their place? This paper discusses the pros and cons of close-range
photogrammetry versus 3D scanning and airborne lidar in a variety of applications including
documentation, archaeological prospecting, spatial analysis, conservation, and change detection. From
sub-millimeter to landscape-scale projects, choosing the best approach can be a complicated and
confusing process. Issues affecting this decision-making process will be discussed including time and
resource costs, field conditions, problematic surfaces, computing requirements, data resolution, accuracy
and metadata and archiving concerns. A variety of case studies comparing photogrammetric and
scan/lidar data capture and processing will be reviewed from inscribed surfaces to whole vessels,
excavated features to standing structures, and landscape surfaces to buried features

Little Houses on the Hillside: Community Ritual in the Mid-Fraser Canyon of British Columbia
Keatley Creek is one of the more impressive socially complex villages in existence today on the British
Columbia Plateau in the Mid-Fraser region of interior British Columbia. With 119 pithouse depressions
spanning approximately 3,000 years, Keatley Creek has been the source of considerable archaeological
research. Five small houses previously defined as "ritual" architecture, and men’s secret society houses,
are located on a northern terrace peripheral to the site’s core. Despite a comparative literature noting the
lack, or non-existence, of secret societies ethnographically on the British Columbia Plateau, the most
recent evaluation in 2010 adamantly defends this notion. I posit a new interpretation of these proto-
historic houses relying on two lines of evidence: archaeological data and a rich regional ethnographic
record. This new glimpse into the little houses suggests that ritual does play a significant role in the
village, but is not restricted to the role of men and secret societies, but extends into gender and life stage
ritual.

Cached, Dropped, or Ritually Deposited? Dimond Knoll’s Enigmatic Lithic Assemblage and the
Archaeology of Motive
The Dimond Knoll site (41HR796) was discovered along Cypress Creek in northwestern Harris County,
Texas, within the upper Gulf Coastal Plain. Extensive data-recovery investigations at this small floodplain
mound revealed that mobile foraging groups had visited the site regularly for nearly ten millennia, leaving
behind artifacts spanning the Late Paleoindian (ca. 8000 B.C.) through the Late Prehistoric (ca. A.D.
1500) periods. Several pit burials were identified during excavations, along with a substantial quantity of
artifacts related to food preparation and tool manufacture. One enigma surrounding the site’s rich material
inventory was the realization that 411 of the 834 formal bifacial tools were in pristine condition rather than
broken or exhausted. Given the scarcity of local tool-quality raw materials, it is rare in the region for
nearly 50 percent of a site’s stone tool assemblage to retain utilitarian value. This paper explores various
cultural and environmental factors that may have gone into shaping the anomalous artifact patterns that
endured at the site across many centuries.

Connecting Basins through Plateaus: Late Holocene Hunter-Gatherer Mobility and the
Circulation of Goods in Southwestern Patagonia (Santa Cruz, Argentina)
The purpose of this contribution is to summarize the results of an ongoing research aimed at
understanding the settlement patterns and mobility strategies implemented by hunter-gatherer groups in
the harsh environments of southern Patagonia in Late Holocene times. A growing body of evidence
suggests that, in this time period, peri-Andean (San Martín-Tar, Viedma) and extra-Andean (Cardiel)
lacustrine basins (around 250 masl) were used year-round while the intervening basaltic plateaus
(around 900-1100 masl) seasonally functioned as guanaco (Lama guanicoe) hunting grounds and least-
cost paths linking different basins. In this presentation we will discuss the main lines of evidence
supporting this assertion (e.g. rock art, lithic technology, archaeofaunal assemblages, radiocarbon dates), presenting new information coming from recently investigated archaeological localities (9 de Julio and Laguna del Pajonal, Tar-Viedma plateau). In particular, we will focus on those aspects of the regional archaeological record that suggest the existence of local differences that allow ranking of basins and the plateaus and provide clues about the way in which different places were connected. The latter will be discussed on the basis of a model about the regional circulation of goods, especially of artifacts made on obsidian and limolite which are toolstones whose specific sources are known.

[161] Rio Amarillo: A Town on the Edge of Ancient Copan
Investigations at the site of Rio Amarillo have provided information concerning the lives of elites and commoners in this pre-Columbian town located between the city of Copan and the interior of Honduras. The excavation of contexts from the Early Classic through the Postclassic period has elucidated relationships between the site's inhabitants and their neighbors to the east and west. During the Early Classic, Rio Amarillo ceramics were largely locally made, but by the Late Classic period the site was integrated into the politics and economy of Copan with goods imported from that center. Following the collapse of Copan, locally produced ceramics again became the norm, although the inhabitants remained part of a long-distance exchange network involving goods from Highland Mexico, Guatemala, and the interior of Honduras. Scholars debating the ethnic identity of Rio Amarillo's people have suggested that the East Group in its core was not Maya due to its settlement pattern, but new research suggests that this area was integrated into the political strategies of Copan and that the odd pattern of settlement may reflect a palimpsest of occupancy. A residential area to the northwest of the core, however, embodies a fusion of Maya and central Honduran styles.

[137] Integrating GIS and Political History: The Ancient Maya City-State of Minanha
The ancient Maya city-state of Minanha experienced a florescence during the Late Classic period between the years of A.D. 675-810. During this period, the Minanha epicenter emerged as a polity capital in what is now the north Vaca Plateau of west-central Belize, which is suggested to be a contested frontier zone between the antagonistic centers of Caracol and Naranjo. The present study addresses Minanha's spatial position in this landscape by incorporating viewshed analysis and cost surface analysis, which model the territory that is visible from a specific location and the easiest routes of travel across a landscape, respectively. These GIS techniques have been applied to the Minanha city-state and suggest that the epicenter was strategically placed in a location with commanding vistas over the surrounding landscape with the ability to monitor and control important routes leading southeast to Caracol and northwest to Naranjo. By integrating GIS analysis with the regional political history, the rise and fall of Minanha within a perceived frontier must be viewed in a more holistic context that is most clearly illustrated through a model of embedded heterarchies.

Barse, William (Smithsonian Institution)
[129] Genetic Stratigraphy, Paleosols, and Orinocan Archaeology
The recognition of chronologically synchronous paleosols along the Orinoco River dating from the Pleistocene-Holocene transition and later periods of the Holocene reflect broad patterns of deposition, pedogenesis and weathering that serve as proxy data for patterns of climatic stability and change. The repeated occurrence of stratigraphic horizons with common archaeological "index fossils" of well-dated lithic complexes or ceramic assemblages can be understood within a framework of genetic stratigraphy. Early Archaic components and later Formative components are reviewed using the concepts of genetic stratigraphy. Although these concepts were developed originally for the analysis of ancient stratigraphic sequences in sedimentary rock, they are applicable to any landform that is undergoing aggradation or
erosional processes that resulted in a terrestrial stratigraphic section. Widespread paleosol horizons can be viewed as allogenic strata that can be linked to broader climatic events both within and beyond the Orinoco Valley. The framework provided by a model of genetic stratigraphy is a powerful tool to integrate the archaeological record with patterns of climate change in the northern tropical lowlands.

[242] Human Mobility Patterns in Prehistoric Tutuila, American Samoa: Evidence from Strontium, Sulfur, and Oxygen Isotopes

In this study, we examine evidence of mobility patterns in ancient humans from Tutuila Island, American Samoa, using stable isotopes of strontium, sulfur, and oxygen. Our study sample includes 32 radiocarbon-dated burials from six coastal sites that span ca. 1600-100 B.P. Previous work identified dietary heterogeneity in this sample, with females and subadults of post-weaning age consuming higher trophic level resources than males. This pattern may reflect dietary variation linked to division of labor practices, dietary preference, or may instead reflect mobility practices of specific individuals. To evaluate these competing hypotheses, strontium isotope analysis was conducted on tooth enamel samples from 21 individuals, oxygen isotope analysis of bone bioapatite was conducted on all 32 burials, and sulfur isotope analysis was conducted on 12 burials and three faunal samples. The results and limitations of the study will be discussed in regard to ethnohistoric and ethnographic data sources on human mobility patterns in American Samoa.

[71] Lithic Technology and Human Ecology: An Evidence-Based Paradigm for Archaeological Research

Most archaeological research on chipped stone artifacts today remains dominated by a largely implicit paradigm based in researchers’ daily experience with 21st-century industrial technologies. But decades of accumulating evidence from diverse research programs spanning multiple geographic regions, forms of social organization, and time periods demonstrates that this implicit paradigm poorly fits lithic technology and can lead to significant misinterpretation of the archaeological record. Because of the critical importance of lithic technology to human biological and cultural evolution, and the ubiquity of lithic artifacts in the archaeological record, the misapplication of an inappropriate interpretive paradigm has significant impacts on our understanding of the human past. We urgently need to replace this implicit paradigm with one that explicitly recognizes the mechanical and social processes that underpin lithic technology, and its important linkages with human ecology. Geoff Clark’s career-long emphasis paradigmatic bases for knowledge of the human past, and concern with human ecology makes this symposium the appropriate place to call for a paradigm shift in the way archaeologists study and make sense of lithic assemblages. We offer a conceptual framework and example research projects that illustrate a more useful approach to this key component of the global archaeological record.

[201] Facing Climatic Hazards: Paleolithic Foragers vs. Neolithic Farmers in Asia

The paper compares archaeologically reconstructed survival strategies of successful and failed Paleolithic groups of hunter-gatherers in Asia to responses adopted by Neolithic farmers since annual cultivation began and the number of sedentary communities increased. When African Lower and Middle Pleistocene humans dispersed into Eurasia they found uninhabited areas available even during abrupt climatic events. Failures to recognize the intricacies of the emerging calamities ended with extinction. The Upper Pleistocene provided similar conditions although humans living in the subarctic conditions were prone to abrupt climatic changes. The impacts of climatic hazards were and are generally more important among agro-pastoral societies. The rapidly evolving sense of territorialism with the establishment of permanent villages and the formation of early chiefdoms forced the adoption of new conceptual and technological buffering means (e.g., storage, raiding neighbors) to ensure the survival of the affected communities.

[208] Forces on the Forelimb in Traditional Archery Measured in Hadza Hunter Gatherers: Implications for Interpreting Archaeological Skeletal Collections

Skeletal analyses of Mesolithic archaeological collections often look for evidence of bow and arrow usage in forelimb bones. However, few studies have examined the forces of traditional archery on forelimbs, and measurements of these forces during traditional archery may improve archaeological investigations of bow and arrow use in skeletal samples. From video recordings of ten adult men and four boys of the traditional Hadza hunter-gather tribe in northern Tanzania, calculations of forces acting on their forelimbs and velocity of the arrows were made as they participated in an archery competition involving hitting targets at four different distances. As expected, arrow velocity was strongly, positively correlated with the force used to draw the bow. However, there was no relationship between the target distance and forelimb forces during the draw, nor was there a relationship between target distance and arrow velocity. Comparisons between adults and juveniles indicate that draw force and arrow velocity were positively related to body size; adults used greater forces resulting in higher arrow velocities. Our findings indicate considerable force acting on the forelimb, particularly the phalanges, during traditional archery. We discuss the implications of these results for interpreting skeletal collections in populations that may have practiced archery.

[17] Human Evolution at the Headwaters of the Nile

This paper will focus on the results of the first season of fieldwork conducted as part of the long-term geoarchaeological project looking at human evolution and paleoenvironmental change in the Kagera catchment and Lake Victoria. The discovery and excavation of new Early–Middle Stone Age sites in stratified and dated contexts will be described. The geomorphological context of the sites in relation to the long-term landscape evolution of the River Kagera and paleoenvironmental change will be discussed. The excavated sites are the first Early–Middle Stone Age sites in Uganda to be dated using modern chronometric dating techniques. Preliminary results raise numerous interesting questions regarding behavioral adaptations, environmental adaptations, and population dynamics of Middle Pleistocene hominins for future research.

[244] Technological Organization of Artifact Surface Scatters on Barrow Island

No evidence of late Holocene artifact industries has been identified thus far from open-air sites on Barrow Island, suggesting a relatively pristine late Pleistocene/early Holocene surface record. Artifacts manufactured from non-local materials tend to be extensively reduced. Implements are uniformly small, often heavily retouched, and retain little further utility as tools. The use of local siliceous limestone reflects primary production of large, single platform cores and percussion blades. Both aspects of the surface record are consistent with expectations that highly mobile subsistence-settlement systems characterized the Pleistocene and early Holocene of arid Australia.
Basham, Matt (Texas State University)
[199] Living on the Edge: Archaeological Investigations along the Canyon Edge, Eagle Nest Canyon
The canyon edge surrounding Eagle Nest Canyon was used by Native Americans for thousands of years. It was a crucial component of the landscape, an intermediate zone with access to both upland and river valley resources. The most common archaeological remains encountered in the canyon edge zone, burned rock features, are ubiquitous components of the archaeological record in the Lower Pecos Canyonlands. Research conducted during and after the 2013 Texas State Archaeological Field School investigated numerous burned rock features along the canyon edge. Most of these features appear to be the remains of individual earth ovens. The remains were composed of burned wood, plants, and rocks. Analysis of the remains has revealed a variety of behaviors associated with the construction of these features including the selection of wood, rocks, and plants from the uplands and valleys, the arrangement of the rocks into heating element configurations, and the selection of locales where deeper sediments were present. These behaviors represent a specific subsistence strategy that allowed people to incorporate plants, such as lechuguilla and sotol, into their diet. The presentation will outline the methodologies used, the findings, and recommendations for future investigations.

[299] Three Dimensional Scanning of the Chipped Stone Tools from Direkli Cave/Kahramanmaras/Turkey
Newly initiated research at Direkli cave is helping to define an initial understanding of Epipaleolithic hunter-gatherer traditions in the central Taurus region of southern Turkey. Detailed analysis of the Direkli chipped stone tools and faunal assemblage suggests that the cave functioned as a short-term logistical camp in the late Epipaleolithic. Especially geometric microlith such as lunates and triangulars were used by occupants of the cave. The cave was used primarily in the late summer and fall. This work uses a different approach from the traditional methods used on chipped stones. Some chipped stone stools from Direkli Cave were scanned by a 3D scanning device and observed different features on lateral edge which was backed of geometric microliths. This poster represents traces of production sequences of geometric microliths in Epipaleolithic period of the Direkli Cave.

[80] It’s Always Field School Around Here: Longwood Archaeology and the Life Skills That an Archaeological Education Provides
Founded in 1980, the Dr. James W. Jordan Archaeology Field School at Longwood University has grown from a summer opportunity for undergraduates into a multi-faceted program that is rich in fieldwork and laboratory opportunities for students year-round. The hands-on approach to learning has been an effective way to engage students and maximize learning. From our perspective, the archaeological methods, skills and view of the world transcend archaeology and are readily applicable to a broad range of career paths for students. The efficacy of this approach is demonstrated each year as dozens of Field School alumni return to share their experiences of “Life after Longwood” with current undergraduates. They do this as they participate in the excavations of the field school as a part of our annual Archaeology Field School Crew Luau and Alumni Weekend. What we have gleaned from these alums is that, because of the Field School, they have skills that have allowed them to lead satisfying lives in myriad career trajectories and in a meaningful sense, through archaeology; they have never really left Longwood.

[156] Radiocarbon Dates for the Guadalupe Mountains Red Miniature Paintings
Nine paint samples and eight unpainted rock backgrounds were collected from four sites within the Guadalupe Mountains of the Lincoln National Forest for plasma oxidation and accelerator mass spectrometry radiocarbon dating. Unfortunately, only five paint samples contained sufficient carbon for dating: 3260 ± 50, 3600 ± 150, 4400 ± 80, 3285 ± 40, and 1520 ± 45 years B.P. Carbon levels in the unpainted rock backgrounds were not negligible; however, paint samples had significantly more carbon. We are cautiously confident in the ages reported here. Locally, dates span from the Middle Archaic Hermit’s Cave / Lake Avalon phases with one date in the Terminal Archaic early Hueco phase. The
dates provide chronological context for specific communal hunting strategies in the Guadalupe Mountains, including use of nets, atlatls, antler snares, and rabbit sticks. Regionally, these results strengthen parallels between the Guadalupe red miniature paintings of New Mexico and the Red Linear Style of the Lower Pecos Canyonlands in Texas. Multiple lines of evidence using both physical and archaeological sciences are necessary when evaluating chronometric data.

Ceramic Stylistic Diversity from Slave Quarter Sites at the Hermitage, TN

Variation in enslaved people’s access to goods has been interpreted spatially as a result of proximity or distance from the owner’s main house. In this poster, we evaluate these conclusions with data from Andrew Jackson’s The Hermitage. Recent analysis by the Digital Archaeological Archive of Comparative Slavery (DAACS) of slave quarter assemblages indicates five phases of occupation across the Hermitage property. In light of this fine-grained chronology, we explore the influence of Jackson’s program of housing standardization and the proximity of domestic contexts to the mansion on enslaved people’s access to market goods. Specifically, we examine whether diversity in the decorative techniques and elements on ceramics acquired by enslaved people shifts as a result of these two variables. This detailed temporal and spatial analysis is possible through the specific, attribute-based recording of decoration called for in DAACS protocols.

Charting the Ancient Maya of Northern Belize: Materiality, Place, Identity, and the Legacy of Norman Hammond

Before the advent of the Barton Ramie project, archaeologists viewed Belize as a cultural backwater to the more-advanced Petén Maya. However, Norman Hammond’s British Museum-Cambridge University Corozal Project in the 1970s charted the regional settlement in northeastern Belize and dismissed those earlier views. Additionally, the discovery of early, pre-Mamom ceramics and architecture at Cuello was foundational; it increased our understanding of these early communities, and demonstrated the presence of a northern Belize regional ceramic sphere, known as Swasey. The results of the Corozal Project surveys, the later work at Cuello, Nohumul and La Milpa, and the work of other scholars in the region revealed an early, vibrant, and in many ways, unique, regional cultural phenomenon centered around and along the Rio Hondo and the New River. From the preceramic to the Classic period, northern Belize’s domestic, lithic, ceramic, and architectural remains demonstrate this distinctive regional style, both inspiring and inspired by the larger regional developments to the west and north. This paper will revisit northern Belize’s history, charting the shared ideology and technology evident in the material manifestations, both big and small, which characterize this region, and the impact of Norman Hammond’s work on our understanding of them.

Bauer, Andrew (University of Illinois)

Land Use, Social Landscapes, and Trajectories of Change: Examples from Early South India

As the opening presentation of the session, this paper calls attention to the importance of understanding ancient land use to a variety of different archaeological research programs. It argues that the detailed reconstruction of spatial and temporal practices of how people engaged with their physical environments is critical to both interpretive and ecological approaches to landscapes, allowing archaeologists to better investigate symbolic dimensions of spatial practice, social memory, political practices and inequalities, as well as long-term human environment interactions and the historical agency of both humans and non-humans. Improvements in methodological and analytical techniques for reconstructing ancient land use and spatial practices are thus broadly applicable to many archaeological research questions. To make these points this paper will use examples of remote sensing, GIS, archaeological survey, and paleoecological analyses of South Indian archaeological contexts that speak to the emergence of institutionalized social inequalities, changing strategies of land use, and socio-environmental histories.

[243] Learning, Habits, and Archaeological “Cultures”: Thinking about “Communities of Practice” across Time and Space

For good reason, much of the archaeological work engaging with communities of practice has involved the ethnoarchaeological study of contemporary crafts, with a few noteworthy studies of archaeological materials from contexts with tight chronological and spatial control. Taking a case from the Bronze Age Black Sea, this paper argues that “communities of practice” may be helpful in thinking about craft production over broader scales of space and time, and allows us to think differently about the relationship of technology to communities, not simply recasting technological approaches such as chaîne opératoire with new lingo. I hope to show that the communities of practice framework provides a way to theorize how communities—and in turn, what we might identify as archaeological “cultures”—emerge from sharing technological practices in a way assumed but never explicitly addressed in previous technology-based approaches.

[111] The German Ridge Project: Living on the Edge in the Hoosier National Forest of Southern Indiana

The German Ridge Project, a multiyear joint research effort between the Hoosier National Forest and Indiana University, focuses on 19th-century German American farmsteads and settlements in the uplands in southern Indiana. The research documents the lives and culture of Perry County's early German American settlers, who were often, very literally, "living on the edge" as they cleared and farmed the narrow ridges of what is now the Hoosier National Forest. The lives of these settlers have been documented through oral history, photography, and historic archive records as well as by archaeological field investigations that employed university field schools and Passport in Time volunteers.

Two farmsteads, occupied from the middle 19th through early 20th century, were mapped and excavated during 2012. In 2013, we revisited one of these farmsteads as well as investigated some "mystery domes," rock piles whose purpose and age of constructing (historic or prehistoric) are unknown. A variety of survey techniques including shovel testing and remote sensing were used to examine the domes and solve their mysteries. Findings of this work will be shared through interpretive signs placed in the area, a website devoted to the German Americans of Perry County, and local history museums.

[32] Bioarchaeological Contributions to Late Pithouse Period Mimbres Studies: Data from the Harris Site

Burials resulting from excavations at the Harris Site (both recent and many decades ago) have provided both biological and mortuary data for use in reconstructions of Late Pithouse Period (A.D. 750-1000) life in the Mimbres Valley of southwest New Mexico. Results of bioarchaeological analysis indicate significant roles for women and children in Mimbres society and suggest special importance of certain family lineages within these communities. Atypical mortuary treatments from Harris Site burials are compared to those typically observed at Mimbres sites. These burial contexts are explored to further understand social and ritual behaviors both within the community and the regional culture system. Biological indicators of
the skeletal remains portray a mostly healthy population with few pathologies or nutritional deficiencies. These data are proving to be important for consideration of ecological and social dynamics during the Pithouse Period.

[344] Through Morris’ Eyes—Historic Images from Aztec West, GIS, and Re-thinking Aztec Ruins

New data points gleaned from original Morris photographs are combined with unpublished historic accounts of additional room features, architectural data, kivas, and surrounding sites on the landscape. These data have then been entered into a GIS format and analyzed from micro to macro scale (room to region) in order to present new ideas about the accretion, development, desertion, and landscape of Aztec Ruins.

**Beach, Timothy (Georgetown University), Sheryl Luzzadder-Beach (University of Texas, Austin), Thomas Guderjan (University of Texas, Tyler) and Samantha Krause (The Maya Research Program)**

In the tradition of Karl Butzer’s geoarchaeology, we synthesize our sedimentary and paleoecological evidence from 2010 to 2014 to investigate the physical and anthropogenic formation of wetlands and floodplains in Northwestern Belize. Our lines of proxy evidence include extensive AMS dating, micromorphology, stratigraphy, magnetic susceptibility, general chemistry, carbon isotopes, elemental analysis, pollen, phytoliths, and charcoal from dated strata in an array of wetland and floodplain environments. These lines of evidence provide a range of floodplain formation rates and show significant differences in the timing, use, and crop types of wetlands over the Late Holocene. Mapping and excavation into water management features such as canals, dams, and reservoirs suggest the intricacy of Ancient Maya land management as well as intertwined natural processes in this dynamically changing landscape. Although many are clearly Maya fields, some wetland features appear to be largely natural, though even the most natural have human imprints. Remote sensing imagery and analyses is allowing us to extend our areal understanding of human and natural wetland uses and patterns.

[322] Rebuilding the Past: 3D Printing in Archaeology

Recent technological advances allow archaeologists to engage in virtual curation of artifacts. Archaeologists routinely utilize tools such as three-dimensional (3D) scanners to create digital copies of artifacts to share both for research and educational purposes. Less attention has been paid to 3D printing, however, which has the potential to expand public outreach in archaeology by creating physical copies of artifacts, bones, and other vestiges of the past. This paper focuses on recent efforts at UWF’s Division of Anthropology and Archaeology to both scan and print physical models of artifacts using a NextEngine 3D scanner and a Makerbot Replicator 2X 3D printer. To date, we have scanned and printed skeletal remains, prehistoric and historic ceramics, and parts from historic shipwrecks located around Pensacola. Scanned models and copies of artifacts can be used to demonstrate archaeology in K-12 and undergraduate classes, can be shared through online social archaeology networks such as OpenContext or GitHub, and can form the basis of a tactile museum display for the visually impaired. Finally, this paper outlines some of the challenges inherent in today’s 3D printers and ways to overcome them in order to provide the public with a better understanding of the human past.
Creating “Archaeological Imaginaries” of Consumption: Colonial Legacies within Archaeological Meaning Making

A central tenet of the archaeological process of meaning making is the association of material remains in the present with identities in the past. Changes in material remains represent shifts in dispositions, which signify changes in past peoples. Material remains end up acting as proxies for people within archaeological interpretation; however, how are people differentiated when they are all using similar material goods from similar sources? The current discourse within historical archaeology draws heavily on the archaeology of capitalism to engage with the more recent past; however, this conceptualization relies on an underlying colonial framework that ultimately serves to exclude Indigenous peoples in the past from discourses of modernity, requiring an existential loss of their Indigenous identities. This paper explores the process of identity negotiation within consumption through multi-generational, 19th-century Mohawk sites in Ontario. This exploration emphasizes the role we as archaeologists play in creating ‘archaeological imaginaries’ of the past, where Indigenous peoples consumed goods in an essentially different manner than non-Indigenous peoples. By deconstructing these essentialist binaries, more accurate conceptualizations can be explored while contributing to new discussions about Indigenous consumption and material remains.

Beaver, Joseph (University of Minnesota Morris) and Ian Buck (University of Minnesota Morris)

Teaching Hunter-Gatherer Lifeways through Gamification

The hunter-gatherer lifeway, despite being fundamental to human existence, is completely unfamiliar to undergraduate students who have lived their whole lives in an industrialized complex society. Experience has shown that students need more hands-on, experiential learning to achieve a satisfactory understanding of a lifeway so radically different from their own. We present an interactive game-style computer simulation of a hunter-gatherer society’s way of life, in the tradition of such “games” as Oregon Trail. The game places particular emphasis on decision-making regarding seasonal movement, food choices, and division of labor by hunter-gatherers. In the game, the student player makes iterative decisions as to which members of the society will engage in which subsistence-related tasks, as well as which foods will be ignored or deliberately targeted. The game simulates the outcomes of these decisions, providing feedback on the health (and especially hunger levels) of the individual members of the hunter-gatherer group.

Beck, Jess (University of Michigan - Museum of Anthropology)

Age, Identity, and Burial in Copper Age Iberia

Recent work has called attention to the significant number of subadults recovered from late prehistoric burial contexts in western Iberia. However, non-adult burials are also documented at some of the well-known, large-scale centers of the Copper Age of southeastern Spain, where adults and subadults are represented in both commingled and individual burials. The implications of the inclusion and mortuary treatment of subadults at such centers of social and economic power have yet to be satisfactorily explored. Here, I discuss the implications of the presence of non-adults on the formation and representation of community identities, with particular emphasis on the case of Marroquíes Bajos. At this site, salvage excavations have yielded evidence of five concentric ditches and one adobe wall that encompass an area of approximately 113 ha, making it one of the largest ‘macro-villages’ known for the Iberian Copper Age. Marroquíes Bajos is a particularly relevant case because non-adults occur in formally and chronologically distinct funerary contexts; their remains appear in secondary and commingled contexts, communal burials, and grouped individual burials beneath structures. The significance of subadult burial is explored relative to understandings of status and role in prehistory, as well as ethnographically and archaeologically documented rites of passage.

Beck, Colleen (Desert Research Institute) and Ben McGee (Astrowright Spaceflight Consulting LLC)

The Bottle as the Message: Solar System Escape Trajectory Artifacts

The notion that extraterrestrial intelligence may one day encounter artifacts of human technology has been incorporated into the design of spacecraft set on trajectories beyond the Solar System. By applying archaeological methodology to the analysis of these artifacts, it is argued that the physical attributes of our spacecraft themselves convey a rich narrative about our civilization typically ignored in technical and academic considerations of extraterrestrial communication. The informational value of these “messages in a bottle” that have received so much focus for future extraterrestrial communication pale in comparison with the informational value of the bottle, the spacecraft itself.
Becker, Kenneth [45] see Duryea, Dean

The Mojave Desert of California contains a rich and varied archaeological record reflecting over 10,000 years of human occupation. Vast areas of desert pavement containing abundant stone suitable for stone tool production blanket the lower bajadas and alluvial fans located there. Many of these desert pavements were quarried over millennia for tool stone resulting in concentrations of well-preserved segregated reduction loci (SRL) representing single reduction events. These pavement quarries can cover an area of more than 400 ha and contain thousands of SRLs and tens of thousands of individual artifacts. The sheer numbers of artifacts present a challenge to fully inventorying and evaluating these resources. During a 10,000-acre survey at Fort Irwin and the National Training Center, Statistical Research, Inc., developed a suite of field methods and postfield analyses using Global Positioning System and geographic information system technologies to quickly and efficiently record and define these sites in their entirety. These methods reduced field time by at least 50 percent over traditional recording methods.

Becker, Sara (York College of Pennsylvania) [64] Community Labor and Laboring Communities within the Heartland and Hinterlands of the Tiwanaku State (A.D. 500-1100)

Organized labor is a known key component to the development of state-level societies. Understanding how labor is organized and in what fashion can help elucidate activities performed by individuals in their daily lives, as well as production within an emerging complex society. Tiwanaku, with its multiethnic neighborhoods in the heartland of the Titicaca Basin, Bolivia and various settlement clusters in their colony near present-day Moquegua, Peru, provides the opportunity to compare labor between various groups within the state. Specific skeletal evidence of activity (i.e. musculoskeletal stress markers and osteoarthritis) from Tiwanaku individuals was compared to the archaeological record to infer how habitual activity varied within this state. Labor rates within the heartland showed some degree of difference between elite areas and non-elite areas, possibly indicating centralized labor control. However, the communities of non-elite laborers in various communities, including colonists, had activity patterns that did not indicate that these people worked at the behest of elites as some kind of serving or slave class. Instead, the data from this study suggested that these people worked at a variety of tasks and that they were more embedded laborers, akin to a guild, within the state.

Becker, Marshall (West Chester University) [191] Tracing Identity in Ceramic Production Techniques: Kilns and Firing Pits in Mesoamerica

Despite the use of well fired ceramics within the Maya realm, from the Pre-Classic to the Post-Classic period, firing technologies remained extremely simple. The elaborate painted wares and polychromes as well as high temperature ceramics were produced by extremely skillful potters using varieties of open surface firing. Enclosed production systems, or rudimentary kilns, are known from extremely few locations in Mesoamerica, all of them beyond the Maya region. The various identified technologies and their distribution provide clues to cultural conservatism in this facet of Maya material culture over at least two millennia.

Beekman, Christopher (University of Colorado Denver) [189] The contexts of Archaeologically Recovered Shaft Tomb Figures in Central Jalisco: Who Do
ABSTRACTS OF THE SAA 79TH ANNUAL MEETING 49

They Represent?
The hollow ceramic figures looted from shaft tombs remain for many the defining features of western Mexican archaeology, perhaps because fresh research into their use and meaning stalled out over 40 years ago. The identity of the individuals portrayed in the shaft tomb figures remains unclear, and different proposals have tended to assume rather than demonstrate who the figures represent. This paper considers in the aggregate those figures that have been professionally recovered from archaeological contexts in the central valleys of the state of Jalisco. I consider in particular the location of the tombs where they were found, and the accompanying burials and artifact assemblages. The goal is to narrow the range of possible interpretations, and to consider their significance for ancient sociopolitical organization. I caution that the conclusions of this study cannot be applied to all figures from shaft tombs. Shaft tombs and the mortuary practices associated with them differ across western Mexico and cannot be assumed to be uniform in nature.

[190] The Ancient Mosquito Coast: Why Only Certain Material Culture Was Adopted from Outsiders
The archaeological cultures of the Mosquito Coast of Honduras share a strong cultural affiliation with Lower Central America, although often obscured by a strong Mesoamerican veneer manifested in elite goods and architecture. This paper explores the relationship between the Mosquito Coast of Honduras and their neighbors during Periods V and VI (A.D. 500 to 1520) and examines the utilization of these external connections by local elites. Rather than viewing this kind of external influence as a passive response to powerful neighbors, these outside elements are discussed as evidence of internal political strategies, revealing something about the situation in which these developments happened. The adoption of external elements varies throughout this large region, and these differences are discussed.

Beisaw, April (Vassar College)

[323] Nationality as a Means of Understanding Native Identity after European Arrival: The Susquehannock Case
Archaeological narratives of Native Americans during the Contact period (circa 1500-1800) often focus on rates of assimilation or declines in population. Recent efforts to decolonize archaeology encourage us to move away from relying on European artifact counts to create chronologies—more European goods does not necessarily mean the site is more recent and the inhabitants more assimilated. Instead, these artifacts can be seen as remnants of the "cultural entanglements" that characterize the era. This paper reconsiders the archaeological narrative of the Susquehannock, a Native American group of what is now central Pennsylvania, by viewing them as a nation instead of an ethnic group. Nationality may be superior to ethnicity for understanding cultural entanglements because it is rooted in cultural not biological inheritance. All that matters in nationality is that individuals minimally participate in a shared lifestyle and do not attempt to bring down or overthrow the leadership, outside of accepted mechanisms for political change. Nationalities are also routinely adopted and shed as political landscapes change. Freed from issues of authenticity, a nationality-based archaeological narrative can focus on evidence of Native agency at a variety of scales, from individual, to village, and regional community.

[206] Past Human-Huemul (Hippocamelus bisulcus) Interactions in Patagonia (Southern South America): A Zooarchaeological Perspective
Huemul (Hippocamelus bisulcus) archaeological evidence in Patagonia has been discussed at the local level so far. In this poster, published archaeological data from across the region are assembled in order to evaluate possible longitudinal and latitudinal fluctuations in the past distribution of this endemic Patagonian cervid. We aim at contributing to the natural history of the species, classified as endangered by IUCN, as well as understanding its interactions with human hunter-gatherers through time. The archaeological deposits considered are currently located almost exclusively in the Andean forest, the
forest-steppe ecotone, and the SW coast of southern continental Patagonia. Regional archaeological data display a low frequency of huemul remains through time. Even though huemul was available from the beginning of human occupation in the region, it was rarely included as a prey item until the Middle Holocene (around 6000 years B.P.), and it becomes significantly more abundant in the Late Holocene, particularly in southern Patagonia. Based on this pattern, it follows that huemul bone occurrence in archaeological contexts roughly resembles the species present distribution. Hence, hunter-gatherer predation had little or no influence on the distribution of huemul east and west of the Andes.

Heterarchy in the Copan Hinterlands? The Copan Kingdom Dual Center Administrative Strategy and Patterns of Centralization in Southeast Mesoamerica

An administrative strategy built on the establishment of dual centers in the Classic Maya kingdom of Copan, Honduras, has been well-documented in the El Paraiso Valley and additional examples elsewhere in the Copan hinterlands, including the Rio Amarillo and La Venta Valleys, await further investigation. The question, however, of why this approach, unknown elsewhere in the Maya area, was necessary and effective in the Copan kingdom remains. In this paper, we explore patterns of political centralization and fragmentation documented elsewhere in Southeast Mesoamerica to better understand the context within which Copan elites developed and deployed this unique strategy. We suggest that, in establishing a Copan-style administrative center alongside an autochthonous local capital in the El Paraiso Valley, Copan elites sought to use the heterarchy-trending political practices of the region to their own advantage. By replicating rather than replacing local power structures Copan elites achieved and maintained centralized control through strategies appropriate to a region in which political organization was highly fluid and often decentralized. These strategies stand in apparent contrast with those deployed by Maya elites at Quirigua whose approach to regional control was distinct and, perhaps consequently, short-lived.

Is Digging Archaic? CRM's Misuse of Academic Methodology

Many federal, state, and tribal review agencies overseeing Phase I archaeological surveys require systematic shovel test pits (STP's) as a standard component of any fieldwork to be reviewed. The nominal goals of this strategy are two-fold; 1) to locate buried deposits and 2) to define the boundaries of a site once one is located. In academic archaeology, STP's are primarily used for the latter. Sites are typically discovered through locating surface scatters via erosion, agricultural disturbance, tree falls, or other similar avenues. Numerous studies have been conducted to evaluate the best sampling strategy in placing the test pits throughout a given project area, but there has yet to be an analysis of the efficacy of shovel test pits in locating sites. This study critically examines the usefulness of STP's for site discovery and proposes a change in methodology that would decrease the likelihood of missed sites using a data set obtained over the course of three years in the Southern Plains region. This region is ideal for this type of analysis due to the variety of climate, landforms, and cultural diversity present.

Bellorado, Benjamin (University of Arizona) and Barbara Mills (University of Arizona)

The Ties that Bind: Textile Imagery, Social Proximity, and Communities of Practice in the Northern Southwest

In the ancient Southwest, people communicated their membership in different communities of practice with both high and low visibility attributes simultaneously across several classes of material culture. Archaeologists have identified potential networks of practice through architecture, ceramics, ritual paraphernalia, and textiles, some of which overlap substantially while others are distinct. Throughout the northern Southwest, Ancestral Pueblo peoples used textiles and ritual footwear, and imagery of these items, to signal community and individual identities at several levels. Unlike some types of rupestrine imagery, rock art and building mural imagery dating to the late A.D. 1100s and early 1200s are often found in private household contexts and restricted routes of travel across landscapes and appear to have been intended to communicate social messages to relatively small audiences. Changes in the context and execution of these images may indicate changes in social ties, community organization, worldviews, and how identities were reproduced across space and time. This presentation will document how different communities of practice were expressed by ancient peoples in Southeastern Utah during the Pueblo II and III periods, and how both low and high visibility attributes of material remains signaled changing ties to the Mesa Verde and Kayenta areas over time.

Bison Across the Holocene: What Did Calf Creek Foragers Hunt?

The Calf Creek culture flourished during a relatively brief interval between 5500 and 4800 RCYBP on the North American southern Plains. Conventional wisdom dictates that the bison hunted during this time had completed the evolutionary trend to the modern form Bison bison, a species sporting short, tightly curved horns, and smaller frame than previous species. Crania with horns are rarely preserved during this important interval, leaving little for taxonomists to study. We present a broader picture of changing bison form and associated climate and grassland data through the deep history on the southern Plains. This history of change provides a better understanding of Bison, the largest prey animal available to Calf Creek hunters.

From the Repository to the Classroom: Artifacts as a Portal to the Past

In 1996, the Society for American Archaeology adopted a series of eight Principles of Archaeological Ethics. Principle 4 focuses on outreach and education, and the importance of promoting quality interpretations of the archaeological record to the general public. This paper details a case study initiated by the University of Wisconsin-Madison and the Madison Metropolitan School District (MMSD) where archaeological resources were made available to second, third, and sixth graders in accordance with curricular standards. Funded by a UW-Madison Evjue Foundation Grant, several in-class, hands-on activities were created for area schoolchildren who also visited and interacted with Effigy Mounds on UW-Madison’s campus. This collaborative effort between UW-Madison personnel and MMSD curriculum advisors can serve as a model for other efforts nationwide, in our collective work promoting the value of archaeology in science education.

Bender, Shilo (University of Missouri)

Costs and Strategies of Obsidian Procurement in the Southwest Borderlands

A combination of social network analysis and geographic information systems (GIS) techniques were used to analyze obsidian assemblages from the Southwest borderlands. Chemical data used in sourcing...
the obsidian pieces were collected at the University of Missouri Research Reactor using X-Ray Fluorescence. ArcGIS was used to calculate a terrain cost-adjusted proximity between sites and the sources of obsidian recovered therein. It was then determined whether a correlation existed between the utilized obsidian and the source that could be reached with the least cost in energy. If obsidian was not obtained from the least-cost source, trade routes may have been used to obtain obsidian from greater distances. Trade routes may have resulted in obsidian procurement having a higher overall energy cost but lower individual energy cost than direct source procurement. Establishing obsidian procurement strategies provides vital information on social interactions and how they change through time and space.

[299] Pléistocene Stratigraphy and Geoarchaeology of Lapa do Picareiro, Central Portugal

Lapa do Picareiro is a cave located about 100 km northeast of Lisbon, Portugal. Archaeological excavations since 1994 have unearthed over 7 m of muddy gravel from the cave, containing a rich variety of human artifacts and faunal remains. This poster presents the results of physical and geochemical analysis to establish the depositional and weathering history of the cave. Radiocarbon ages show that the cave fill dates from 9 to > 45 ka B.P. The average sedimentation rate during this period is 0.13 mm/yr, with accelerated sedimentation (0.30 mm/yr) around the time of the last glacial maximum. Gravel in the sedimentary fill is derived from spalling off the cave roof, while silt and clay are contributed by in-situ weathering, slope wash, aeolian transport, or groundwater flow through bedrock fractures. Particle size data show coarse gravel layers associated with cold phases, and a general coarsening upward in the fine fraction. Mineralogical and geochemical data show a shift to stronger chemical weathering and increased organic matter at the start of the Holocene, as forest cover expanded across the region. Isotope records show 13C excursions related to changes in cave hydrology, and 15N values that suggest strong fecal enrichment of the sediments.

Benefield, Paul (Sam Noble Oklahoma Museum of Natural History)

[280] Replicating Calf Creek Lithic Technology

Within Oklahoma, the Calf Creek cultural complex is represented by a variety of basally notched spear points that typically manifest high gloss, color changes, and some marginal translucency due to their having been intensively heat treated. Collections from the Primrose site in Murray County, Oklahoma, and from the Grouse Creek site in Cowley County, Kansas, provide a basis for replicating the prevailing biface manufacturing sequence and identifying when and how many times heat treating was applied during this sequence. Frisco chert is the dominant material manifest at the Primrose site, whereas varieties of Florence chert are dominant at Grouse Creek. I will outline my work on replicating the heat treating and several biface thinning stages associated with these two cherts as documented in the archaeological finds.

Benfer, Adam (University of Kansas)

[153] A Century in Stone: One Hundred Years of Lithic Analyses in Nicaragua

While archaeological knowledge of pre-Hispanic stone tool technologies has greatly expanded since the earliest descriptive accounts from Central America, we still know little about Nicaraguan lithic types and operational sequences. By reviewing one hundred years of publications on pre-Hispanic Nicaraguan stone tools, I begin the process of developing a lithic typology including chipped and ground stone tools. Using this review, I assess the current state of lithic analyses and outline research objectives for future investigations in Nicaragua. Presently, we cannot say much about any stage in the operation sequence of any type of pre-Hispanic stone tools from Nicaragua. We need to focus on identifying raw material sources, interpreting manufacture strategies, conducting experimental use-wear analyses, and developing a comparative microbotanical residue database, among other research endeavors. To initiate this process, I present my preliminary analyses on the stone tool assemblages from the El Rayo and Sonzapote archaeological sites.

Benfer, Bob (University of Missouri-Columbia) [250]

Habitat Discrimination by Phytolith Assemblage

As part of the "Phytoliths in the Flora of Ecuador Project," assemblages of four habitats in Ecuador were studied. Between 16 and 28 surface samples were collected from localities in four environmental zones:
arid coast (Chanduy), dry coastal forest (Jama), moist coastal forest (Bilsa), and moist Amazonian forest (Jatun Sacha). More than 100 types of phytoliths were identified in these samples, and this paper discusses statistical classification of these data by habitat.

Phytolith data propose challenges to any classification. Simple counts treated in a multivariate linear model will not produce successful classifications. This is because some types are more frequent, and some types are more variable than others. Collections differ in total number of types identified. Classification by habitat may require attention to patterns and magnitudes of types with pattern having greater diagnostic power. Relations among types may be non-linear. I will describe here a method that produces 100% correct classification of habitat by phytolith assemblage with a non-linear model. These findings suggest transformations that may be useful for any comparison of phytolith or any rare artifacts. The results tend to validate the use of prehistoric phytolith comparisons since they are shown to produce distinguishable habitats in recent, known settings.

Bengtson, Jennifer (Southeast Missouri State University) and Jodie O’Goreman (Michigan State University)

Ethnicity and Childhood at Morton Village

Morton Village and the associated Norris Farms 36 cemetery sites in Fulton County, Illinois, provide a unique opportunity to synthesize biological and cultural perspectives on life among Mississippian and Oneota residents of the region. Among the research directions developing from new excavations at Morton Village are questions regarding the role that subadult burials can play in informing an analysis of intra- and inter-community social relations. This paper considers what is known about the lives and deaths of Morton children as represented in the cemetery, particularly as this evidence relates to broader intracommunity patterns. Atypical mortuary ceremonialism associated with children’s burials may reflect community signaling of multiethnic identity within a new social context characterized by immigration and intermarriage between Oneota and Mississippian people. Ethnographic and ethnohistoric examples are explored as analogies for such circumstances, while additional mortuary and bioarchaeological research is suggested to further elucidate these ideas.

Chair

Benjamin, Jeff (Michigan Technological University)

The Resonance of the Industrial Past

The silence of ruins evokes absence—a forgotten, irretrievable past—but the archaeological record is nevertheless replete with very specific and accurate sonic information. Once listening is granted status as a primary mode of perception, a demystification of the aural environment of the past ensues. The advent of the industrial era brought with it unprecedented sonic extremes, and the significance of this phenomenon merits closer scrutiny. Many factories and industrial sites, although now mute, are still alive in the memories of those who lived and worked there. This is demonstrated by frequent expressions of a nostalgic reminiscence of industrial sound, delivered once the industrial processes have ceased. The industrial past is resonant; both literally and metaphorically. This paper will first examine the phenomenon of industrial sound broadly, and then move in more closely to look at a particular assemblage of structures at the Quincy Mining Company, in Hancock, Michigan. Through a combination of archival documentation and archaeological evidence, a plausible sonic ‘moment in time’ is produced. The evidence and research is structured in the form of a “historic soundwalk,” as a listener may have experienced this location in the spring of 1916.

Bennallack, Kathleen (University of California, San Diego)

Preliminary Excavation at Wadi Fidan 61: A Multi-Period Neolithic Site in Faynan, Southern Jordan

In the 2012 field season of the Edom Lowlands Regional Archaeology Project, we excavated a site previously only published in survey reports. It is a large, steeply sloped, densely-built site with, at minimum, Pre-Pottery and Pottery Neolithic occupations as well as later, possibly Iron Age, tombs. The 2012 excavation only exposed a very small area, with very complex, well-preserved architecture and surprisingly sparse small finds. Until \(^{14}C\) dates and lithics are processed, we will not know the exact period(s) of the site, but we propose that it may be related to Ghwair 1 and Tell Wadi Faynan. The upper levels contained significant coarse pottery, as well as some lithics and potential “white wares”, diagnostic of early attempts at pottery in the PPNB. The site also contained copper ores (possibly used for making beads and cosmetics) and as-yet unidentified architectural structures inside the buildings, as well as hearths, a pit, and many ground stone artifacts. The size and density of settlement, uniqueness of
artifacts, and complexity of building phases all suggest a long and multi-faceted occupation, which we hope will be the focus of several future excavations.

A Closer Look at Bison Hunting at the Clovis Site, Blackwater Locality 1

Combining recent work carried out by Eastern New Mexico University Archaeological Field School with legacy data from the Clovis site, we are now in a better position to understand Late Paleoindian bison hunting in and around the outflow channel at Blackwater Locality 1. Reconstruction and digitization of previously unpublished research, in addition to current work at the site, gives us a three-dimensional view of these deeply-buried cultural horizons that occur within Unit D and Unit E strata. This analysis ties together the work of many previous excavators and allows us to associate seemingly disparate bone concentrations recovered at different times and with range of excavation techniques, to quantify Late Paleoindian bison utilization at the Clovis site.

Bentley, R. Alexander

Decision-Making and Evolutionary Archaeology

A provocative idea in the evolutionary archaeology literature compared human intentions to those of squirrels and oak trees—i.e., from an evolutionary perspective on long time scales, human intentions didn't matter. Does this apply to decision-making as well? Here we propose a useful means of considering decision-making in cultural evolution, in which the two important 'axes' of variation are social influence (from individual to social) and how well-informed the agents are (from well-informed to poorly informed). We offer that this "map" organized by these two axes is useful in converting archaeological data into particular 'quadrants' of general evolutionary dynamics, each of which features a signature behavioral pattern. When taken together, the map and its signatures provide an easily understood empirical framework for evaluating how modern collective behavior may have changed from prehistory even to the digital age, thus helping to make evolutionary archaeology more clearly relevant to the wider social sciences.

Berdan, Frances (California State University San Bernardino)

Caries Calibration Methods in a Bronze Age Inner Asia Skeletal Sample

This study examined the applicability of two caries calibration methods to a Bronze Age population from Xinjiang Province, China. A skeletal sample of 55 adult individuals from the Tianshanbeilu cemetery (19th to 3rd centuries B.C.E.), housed at Jilin University, Changchun, China, was examined for evidence of dental wear, carious lesions, pulp exposure, and ante-mortem tooth loss. Results showed that the first calibration method (Lukacs, 1995) (5.2%) was slightly higher than the uncalibrated rate (4.8%), and that the second method for calibration (Duyar and Erdal, 2003) produced a similar rate (5.1%) to the first calibration method. However, the calibrated rates are not statistically significantly different from the uncalibrated rate. This is consistent with expectations, as the population had a low rate of carious teeth but a high rate of wear, meaning that most antemortem tooth loss was likely due to wear and not carious lesions. These results are suggestive of a diet low in cariogenic foods, but high in tough or gritty foods. This has implications for the utility of existing caries calibration methods for all ancient diets, and for indirect methods of ancient dietary reconstruction.

[325] From Stone Shelters to Wooden Shiellings: The Use and Abandonment of Early Medieval Caves and Rockshelters on the West Coast of Norway

The paper presents a survey of the excavated caves and rockshelters that were in use during the Migration, Merovingian, and Viking periods (ca. 400-1030 A.D.) along the west coast of Norway from Nordland in the north to Rogaland in the south. Although there are regional differences, the survey shows that caves and rockshelters were intensively used as residential sites as well as ritual sites during the Migration period whereas relatively few of these places were occupied during the Merovingian and the Viking periods. The change, which takes place around 550-600 A.D. can probably be related to general social and economic changes in Scandinavia around this time, when power became more centralized and the utilization of the land was reorganized. During this process, agriculturally marginal areas – in which most of the caves and rockshelters were situated – became more important in the overall economy. This led to the establishment of built architecture and wooden shielings, which to a large degree replaced the natural shelters. Another cause for the change was that caves and rockshelters were increasingly associated with negative forces and supernatural beings during this period.

[250] Lucayan Agriculture and Tool Use: A View from the Central Bahamas

Starch grain and phytolith analyses of flaked stone, ceramic, and shell objects and macrobotanical remains from four early and late period Lucayan sites in the central Bahamas have yielded a variety of crops and wild plants. Many of the stone tools contained residues from more than one plant. A picture of Lucayan food preparation and culinary practices and field preparation techniques is emerging from these finds. The plant processing technologies and techniques will be compared to those found elsewhere in the pre-European Caribbean, and to historic and contemporary cultures of the Caribbean, Amazonia, and Central America.

[323] Lithic Acquisition, Production, and Political Landscapes: The Mission-Era Chumash Interior

Concepts of landscape are infused with political meanings, and utilization of the landscape has clear political implications. The colonial hinterlands of the Chumash Interior in California sheltered many local and refugee indigenous communities long through the Mission era, and was thus a locus of interaction and negotiation between people of varied cultural backgrounds and colonial experiences. Patterns of lithic raw material acquisition and tool production from several late prehistoric-Historic period sites provide a window on to varied utilization of the physical (and thus, sociopolitical) landscape by local communities in addition to newly arrived mission refugees. These data also reveal compelling evidence of continuity in multiple region-specific lithic traditions. Further, the lithic assemblage provides a way of examining the diverse ways people in the region participated in larger systems of regional exchange, showing that many individuals appear to have strategically altered their economic activities, driven in part by political concerns. Taking a landscape approach, I suggest that the ways in which these groups moved throughout the region and employed the landscape for the purposes of lithic acquisition served as a key path through which they negotiated their place in an unfamiliar and increasingly complex physical, sociopolitical, and economic environment.

[141] Virgin Anasazi Archaeology and the Southern Parkway Project

In 2009, as part of the Utah Department of Transportation’s Southern Parkway Project, William Self
Associates, Inc., conducted data recovery at six Virgin Anasazi sites located within 1.6 km of each other on a southern terrace of the Virgin River in the St. George Basin, southwestern Utah. Together, the six sites have (discontinuous) occupations spanning a large portion of the Virgin Anasazi sequence, from the Basketmaker II (300 B.C.–A.D. 400) through Pueblo II (A.D. 1000–1150) periods, although the heaviest period of use appears to be from late Basketmaker III through early Pueblo I. This paper provides an overview of the results of investigations at these sites, which documented more than 100 features, including multiple pithouses, storage cists, and ephemeral brush structures, and produced substantial artifact assemblages of flaked stone, ceramics, ground stone, and botanical and faunal remains, as well as 30 radiocarbon dates. These data are particularly important in light of the paucity of published excavation data and secure radiometric dates for the region. The project results are synthesized in terms of our understanding of the Virgin occupation along this single terrace of the Virgin River and the project’s overall contribution to archaeological research on the Virgin Anasazi.

[206] Exploitation of Birds by Late Prehistoric Forager-Farmers along the Central Des Moines River
Comprehensive analyses of bird remains from the Howard Goodhue Oneota site (A.D. 1190) provide insight on the use of these animals by Late Prehistoric forager-farmers who lived along the Des Moines River in central Iowa. The collection of avifauna includes 614 specimens, with taxa ranging in size from small passerines to ducks, geese, turkey, and swan. They acted as a supplementary, and likely seasonal, food source to the other fauna and farmed resources in the diet of the Oneota. Additionally, modifications on the specimens indicate these animals were utilized as a source of raw material in the production of bone beads.

[107] Virtual Cusco
This project virtually recreated a moment in the history of the indigenous imperial and ceremonial city of Cusco, Peru before it was forever transformed into a European-style colonial provincial village. On a broader theoretical level, this research relates to the way we visualize this most important pre-Columbian city of the South American continent. Methodologically, the project is a feasibility study for the best method to visualize and incorporate past and future data from various fields such as architecture, archaeology, conservation and ethnography, and take advantage of the extensive resources and detailed information collected by various city agencies and individual scholars.

Berrey, Charles (University of Pittsburgh)
Evaluating patterns of regional demography is a critical part of understanding organization and change among complex societies. Among other things such an evaluation requires estimating the size of prehistoric populations, in both relative and absolute terms. For years settlement pattern research has recognized that these estimates are most reliable when they account for both the area and density of human occupation, which, in contexts lacking domestic architectural remains, are often based on the distribution and density of ceramic sherds. Methods have been developed for systematically translating such values into absolute population figures, but only for cases in which surface collections constitute the primary form of data collection in the field. These methods of demographic reconstruction are thus not well-suited to areas with poor surface visibility, as this precludes the reliable calculation of surface artifact densities and often requires substantial amounts of sub-surface testing. This poster presents a technique for making absolute population estimates in such contexts, based on the use of sub-surface artifact densities. The field methods and datasets on which this technique is based are all drawn from regions of the Intermediate Area, but can be adapted to the study of regional demography in other parts of the world.

[19] The Ceramics and Pigments from Piedras Blancas (600-1000 AC), Aguada Culture: Clay
Provision, Technology, and Social Change at the Ambato Valley (Argentina).

Piedras Blancas (600-1000 AC) is a residential site where a well settled, more complex and unequal society developed after the political, social and ideological changes that occurred in the Ambato valley in the IV century of the Christian era. It belongs to the Regional Integration Period (300-1000 AC). Known as the Aguada Culture, these changes spread regionally, encompassing northwestern Argentina. The pottery production reflected those changes within the iconography ("the draconian style").

Technological classes reduced from 44 to 12 while two of them gained popularity: Classes E (common) and A1 (black incise) grew 100% and 30% respectively. The aim of this research is to help to understand the role of these objects in the new society, the continuity and disruptions of the technology, the organization of good production, management and selection of natural resources by this culture and the access to those resources. Pottery sherds, pigments and other possible raw materials found at this site as well as several local clay resources identified within the valley (Catamarca, Argentina), were characterized on their mineralogy, geochemistry and other physical and technological features. Certain minerals and chemical elements are found to be traceable and distinctive from other Aguada styles like the Aguada Portezuelo.

[170] Bamboo and Rice: Plant Residues from Artifacts in Southern China

Plant residues may be used to identify subsistence patterns and trends in general geographic regions. Bamboo and rice residues from artifacts from a range of Neolithic sites are discussed in this paper. While rice remains are frequently identified and sought after in some archaeology sites in South China, other potential domesticates or managed plant taxa such as bamboo are less frequently discussed in the archaeological literature. This paper attempts to document bamboo use in South China during the late paleolithic and early neolithic period.

[241] Of Infants and Elderly: A Bioarchaeological Analysis of a 17th-Century Mortuary Context from Transylvania, Romania

In 2007, archaeologists conducted a salvage excavation inside the Reform Church located in the village of Telekfalva, Romania. At that time, remains of 70 individuals were uncovered and accessioned into the Haaz Rezso Museum located in the city of Odorheiu Secuiesc, Romania. During the 2013 field season, these remains were analyzed for the first time by an international team. In this paper, we present the initial results of these analyses, including the remarkable finding that 69 of the individuals were juveniles. Notably, 71.0 percent of the juvenile assemblage was assigned to either perinatal or fetal age cohorts. Remains of a single elderly adult female were also documented. We draw upon recent literature related to the bioarchaeology of children to interpret the role of this Reform Church as a consecrated burial space for juvenile individuals. In addition, we describe the influence of Calvinist theology on 17th-century Transylvanian mortuary contexts. Lastly, we draw on other studies from Eastern Europe to elucidate the relationship between the juvenile individuals and the single elderly female interred in the Reform Church.

[159] Chronotopes: The Parallel Biographies of Two Humanized Landforms

Among the most important intellectual contributions of landscape theory to archaeology is the ability to reconstruct human trajectories by focusing not on archaeological sites per se but on the interaction of people and landforms. Borrowing shamelessly from Keith Basso and anthropological linguistics, we apply the term "chronotope" (literally, time space) to those landforms that uniquely contain and project the long-term history of a people, from creation to the present. The parallel biographies of Kootenai Falls and Chief Mountain, two major landmarks on either side of the Montana Rockies, are followed through the experiences and narratives of ancestral and contemporary Kootenai and Blackfoot people, respectively. We illustrate how long-term interactions between these groups and their landforms are mutually transformative in tangible and intangible ways.

Bettinger, Robert (University of California-Davis)
[284] Late Pleistocene Lithic Technology on the Upper Yellow River, PRC

There were at least 3 late Pleistocene lithic technologies on the upper Yellow River, Ningxia Hui Autonomous Region: the Initial Upper Paleolithic Shuidonggou flat-faced core technology (41.0-25.0
B.P.), a microblade technology termed the North China microlithic (13.0-8.0 B.P.), and Helan technology, which unlike the first two is not blade based and draws heavily on quartzite as a raw material. Key components of the Helan assemblage include bifaces, unifacial tools, spheroids, choppers, and flake tools, many of which suggest heavy processing, perhaps of plants. The transition from Helan to microblade technology documented at Pigeon Mountain just west of the Yellow River places an upper limiting date for Helan technology between 13.5 and 11.9 cal B.P.; its absence at Shuidonggou just east of the Yellow River fixes its lower limiting date most likely after 20 cal B.P., during a warm-wet period bracketed by cold-dry ones. Because, unlike those representing the two more familiar blade technologies, no Helan assemblage has never been treated in detail, we describe the Helan assemblage recovered in 1995 at Pigeon Mountain, make inferences as to its functions, its relationship with hunter-gatherer mobility, and the broader relationship between lithic technology and climate change in prehistory North China.

[36] Spatial Sovereignties, Archaeological Access and the Big Data Landscape

Spatial data has always carried more political charge than aspatial information, not least in a modern world of nation-states, cadastre-based taxation and location-aware services. In archaeology, the massive advantages of spatially-explicit evidence has been obvious since the early days of the subject, in distribution maps or excavated stratigraphy, and more recently, due to yet greater attention to context, the use of GIS, and sharply increasing overall quantities of digital data. Transparent dissemination of spatial data is increasingly encouraged alongside other forms of 'open' access in archaeology, even if many researchers recognize reasons to act carefully with coordinate information, for example, in order not to enable enhanced looting. Likewise, whilst international projects might see deposition of their final results in data repositories as a responsible act, some might argue this raises as many neo-colonial, cross-border issues about who owns the archaeological resource as it solves. Even so, these questions—of whether we should have spatial gatekeepers and who they might be—are rapidly being taken out of our hands with the advent of citizen-scientific reconstructions of 2- and 3-D spatial models of archaeological phenomena. This paper seeks to foster debate over these issues.

[275] Returning to the Scene of the Crime: The Early Tollan Phase and the Growth of Tula, Hidalgo, Mexico

The analysis of ceramics from Tula and its surrounding hinterland by Healan's Tulane obsidian workshop project in the 1980's led to the identification of an Early Tollan phase dated to between A.D. 900-1000. The ceramic complex associated with the Early Tollan phase is considered a manifestation of major social and cultural changes that took place at Tula during this time period. It is also argued that these changes represented significant transformation in the Toltec ceramic economy. This paper looks at the arguments made in support of the Early Tollan phase focusing on a re-examination of the data and the strength of the ceramic changes. The changes in ceramics include among others a shift from red on brown to monochrome wares, new vessel forms for bowls and dishes, and a decline in complexity of surface decoration, fire clouding and blackened cores. The causes thought to underlie these changes are competitive marketing practices, demographic shifts, and production innovations resulting from the highly dynamic growth and expansion of Tula at this time. This paper seeks to evaluate the validity of this model and whether the data support it.

**Cultural Implications of Late Holocene Droughts Reconstructed from High-Resolution Maar Lake Sediments in the Eastern Trans-Mexican Volcanic Belt**

Climatic change has been invoked to explain periods of cultural change in pre-Columbian Mesoamerica, but a detailed reconstruction of past climate only exists for a handful of sites. We present a reconstruction of 6,000 years of paleoclimatic change in the area surrounding Cantona, a major pre-Columbian city in the eastern Trans-Mexican Volcanic Belt (TMVB). Cantona was an important exporter of obsidian throughout Mesoamerica, and was occupied from 2,550 to 950 cal yr. B.P. Archaeologists have invoked drought to explain the site’s abrupt abandonment, although few paleoclimatic records exist for this area. Our research team obtained a sediment core from the maar lake Aljojuca in 2007. This laminated, 12-meter sediment core features a basal date of 6,200 cal yr. B.P. Analyses of elemental geochemistry, pollen, magnetic susceptibility, and stable isotopes from authigenic carbonates reveal evidence of a climatic shift to drier conditions between 1,160 and 870 cal yr. B.P. Moreover, the intensity and duration of this dry period is unprecedented in the 6,000-year record. Our results not only establish the climatic context for Cantona’s occupation, but also suggest broader coherence of mid to late Holocene climate variability in highland Mexico with that of the Yucatan and lowland Central America.

**Beekeeping Practices in Modern and Ancient Yucatán: Going from the Known to the Unknown**

According to historic documents and scarce archaeological data, apiculture with the stingless bee, Melipona beecheii, was significant in the diet, economy, tribute, medicine, and ritual practices of pre-Columbian Mesoamerica. Beekeeping practices have changed as a result of the introduction of other species of bees, as well as taxation and intensification of honey and wax production under the Spanish colonial regime. Today, the global economy has linked Yucatan’s beekeeping cooperatives with the rest of the world. Current meliponiculture gives us a frame of reference for interpreting the archaeological record. This paper focuses on ethnoarchaeological studies carried out in Yucatan, Mexico. Soil samples collected from underneath and near beehives, as well as samples of honey and wax, were analyzed using Fourier Transform Infrared Spectroscopy in order to identify possible chemical signatures for soil near apiaries. The soil was also tested for pH and nitrate differences with the goal of developing new methods to identify apiaries in the archaeological record. Ethnoarchaeological and soil chemical studies inform conservation efforts aimed to prevent the disappearance of traditional beekeeping practices, the disappearance of the variety of plants necessary to produce honey, and the disappearance of stingless bees themselves.

**Rapid Cooling Events, Human Resilience, and Technological Change: The Case of the Portuguese Upper Paleolithic**

In Western Europe, the Upper Paleolithic is marked by clear regional and diachronic technological differences. Some of these are most likely related with human adaptations to the Late Pleistocene environmental shifts. In this paper we focus on the Rapid Climatic change events and analyze their impact on the main Upper Paleolithic cultural transitions in central and southern Portugal, based on the Adaptive Cycle and Repeated Replacement Models. Our data will also bring insights to issues such as human resilience across the cultural boundaries in technology, land use, and mobility.

A Comparison of Conductivity Survey Results from Three Cemeteries in Georgia

This paper will compare the results from electromagnetic induction surveys at three cemeteries in Georgia: Ocmulgee National Monument Mound C (Funeral Mound) Bluff; Prior Family Cemetery; and McVicker Family Cemetery. Each of these is historic in date, but the use periods range and include Historic Creek, African American Slave (pre-Civil War), and Civil War respectively. Data quality and interpretability varied between cemeteries and each highlights limitations and successes of electromagnetic induction in locating unmarked burials and delineating cemetery boundaries. Comparing these conductivity results with other geophysical survey methods helps to identify conditions under which electromagnetic induction out-performed or under-performed GPR and magnetometry. Electromagnetic induction was a particularly useful technique in cemeteries with unpatterned distributions and measured the boundaries of individual burial pits. Alternatively, electromagnetic induction had more difficulty identifying individual grave shafts under conditions where burials were closely spaced and oriented in the same direction. Despite this limitation, electromagnetic induction aided in delineating cemetery boundaries, served as supportive data to other techniques, and helped reject anomalies as possible burials based on conflicting responses.

Multiple Material Discourses on the Southeast Maya Frontier: Indexing Interaction and Identity through Material Culture in the El Paraíso Valley, Western Honduras

As the archaeological study of frontiers and boundaries increasingly incorporates a focus on agency and interactionist approach to identity, borders once thought impermeable and static have been re-conceptualized as fluid, contingent interaction zones, the physical and conceptual spaces within which networks of interaction are instantiated and identities and affiliations are negotiated. This is particularly true in the Classic period (A.D. 425-825) kingdom of Copan, Honduras, where residents living along the southeastern limits of the Maya area marshaled an extensive array of material culture to craft nuanced salient social identities and affiliations. In this paper we explore one such set of material discourses in the El Paraíso Valley, contrasting pottery found at Los Naranjitos, an elite residential group at the non-Maya center of El Cafetal, with the site's architectural style, construction techniques, and use of open space. While all other diacritics underscore local affiliations, the ceramic assemblage highlights regionally unprecedented access to some of Copan's finest pottery. We suggest that, for the purpose of negotiating affiliations, local El Cafetal residents engaged most actively with Copan elites through media they regarded as meaningful, remaining inured to the norms of foreign canons they deemed less relevant.

Fisherman, Farmer, Rich Man, Poor Man, Weaver, Parcialidad Chief: Household Archaeology at Cerro La Virgen, a Chimú Town within the Hinterland of Chan Chan

Cerro La Virgen is a large coastal settlement located 6 km north of the urban core of Chan Chan, the capital of the Chimú Empire (A.D. 1000-1460). The settlement covers 19 ha and consisted of several hundred household compounds clustered along the Great Northern road to Chan Chan. Although one of the largest and best preserved Chimú settlements in the Moche Valley, it is threatened with destruction by illegal quarrying. We report the results of emergency excavations and our attempts to halt the destruction. Over 450 m² of three household compounds were excavated as well as deep stratigraphic units in middens. Preliminary results indicate a long period of continuous occupation during the Chimú and Inka periods by a mixed community of fishing, farming, and crafting families. Analysis of household middens reveals the economic strategies pursued by households as well as the occurrence of El Niño events during the occupation. Surface mapping indicates the range of household sizes and types during the last occupation of the site. Settlement pattern analysis reveals it was the largest settlement in the rural sustaining area of Chan Chan. We critically examine the role that the community played in the provisioning of Chan Chan.

Obsidian Use in the San Joaquin Valley during the Holocene

Obsidian acquisition, reduction, spatial distribution, and use are all aspects of obsidian research that have been informed by archaeometric techniques and methods. The original source and age of breakage of obsidian artifacts can be determined with some assurance. The raw material for the obsidian artifacts found at sites in the San Joaquin Valley of California originated from sources on the east side of the Sierra Nevada Mountain Range. One particular site, CA-KER-5582, has obsidian artifacts from three major obsidian sources (Casa Diablo, Queen, and Coso) and has evidence for over 9000 years of human activity. Integrating data on source, technology, and time of reduction from CA-KER-5582 addresses site history, formation processes, and stratigraphic integrity. Moreover, in conjunction with some technological aspects of the obsidian debitage, these data provide insight into the changing economic behaviors of hunting and gathering groups in Central California during the Holocene.

Complicated Communities: How Larger Villages Created Complex Societies in Northern Iroquoia

The term “complex” is loaded with a particular kind of meaning in archaeological scholarship. In this paper I strip the term back to its core meanings to investigate cultural phenomena which are interrelated, connected, and associated. In sum: complicated. Between A.D. 1450 and 1600 numerous ancestral Wendat communities rapidly aggregated into large, densely populated settlements. Over the course of two to three generations these communities underwent processes of integration which allowed them to function and persist as large co-residential populations. This paper uses detailed analyses of settlement patterns and material culture to interrogate the complex nature of social, political, and economic life in large Iroquoian village-communities. At one scale it explores the interrelated nature of decision-making, procuring, and producing the necessities of life, and the tangled web of social and kin-based relationships that underpinned those activities. At another scale, it examines how these increasingly complex communities related to processes of social differentiation, alliance-building, and geopolitical realignment which set the stage for the formation of the political confederacies that characterized the contact era.

Birch, Dylan (Art History Society - CSU Los Angeles)

Tula 2013: Reexamining the Palacio Quemado through Its Infrastructure

The Proyecto de Investigación, Conservación y Mantenimiento para la Zona Arqueológica de Tula 2013, directed by Dr. Robert Cobean focused on the excavation of the Palacio Quemado. Today, the three major ceremonial structures exposed are the Palacio Quemado, Pyramid B and Pyramid C; these buildings form an L-shape and face the Adoratorio that is situated in the center of the plaza. The architectural layout of Tula Grande shares symbolic parallels with Teotihuacan in the Valley of Mexico. The Palacio Quemado served as a ritual centerpiece of Tula’s main plaza. This colossal structure contains three adjacent chambers with similar interior features: a series of stone columns, a compluvium exposing the heavens through the roof architecture, and a sunken patio that could collect rainwater, complete with a drainage system from the Pre-Columbian period. The summer 2013 excavations reopened the work of Jorge R. Acosta at this palace seventy years prior, after a small team of graduate students from Zacatecas, Puebla and the United States unearthed a system of drainage canals that were buried less than 2 m beneath this structure. The following presentation utilizes the summer 2013 Tula excavations to illustrate the ritual identity of the Palacio Quemado in greater detail.

Bird, Douglas (Stanford University) and Rebecca Bliege Bird (Stanford University)

Constructing Martu Country: Mobility and Trophic Facilitation in Australia’s Western Desert

Strategies of travel and land use among contemporary Martu foragers are shaped at multiple scales of
social and economic obligation. These obligations in turn shape ecosystem function and species composition in Western Desert landscapes. Here we describe the contemporary material and political contexts of Martu mobility, and explore factors that influence their ecological expression. At broad temporal and spatial scales, commitments to maintain political and familial networks require extensive travel and encourage both transient residence and material egalitarianism. At more local scales, high residential mobility increases the costs of storage and encourages a reliance on more immediate return resource use and extensive food sharing. For Martu, a more immediate return economy is underwritten by subsistence and logistical mobility structured by patch mosaic burning. These burning practices fundamentally modify habitats and species composition, and have broad implications for understanding the evolution of trophic relationships in the Western Desert.

Bird, M. (Midwest Archaeological Research Services, Inc.)
[155] A “Public Burial Place, a Field of Peace, a Pleasant Place of Resort”: The Forgotten circa 1842-1886 Peoria Public Grave Yard (11-P-835) in Peoria, Illinois
MARS, Inc. completed Phase III data recovery at Peoria Public Grave Yard in 2009. Purchased in 1839 and platted in blocks-lots in 1842, the city set aside burial “ranges” for “poor persons and strangers.” The city ceased interments in 1886, removed all markers, and subsequently established Lincoln Park. Descendants voluntarily vacated some graves (1857-1902). An addition to the 1910 Carnegie library, which occupies the former cemetery grounds, was planned in 2009 and has since been built. Field investigations exposed 304 features but only excavated the 86 within the footprint of the library addition. The features appear to coincide with the lots as platted and suggest grouped family interments. MARS, Inc. excavated the remains of 12 men, 18 women, and 58 juveniles. The demographic profile illustrating age at death highlights a high infant mortality and suggests a health risk to women during their child-bearing years. Identified coffin shape included primarily hexagonal with fewer rectangular, octagonal, septagonal, anthropomorphic, and tapered. The simple nature of some of the infants’ coffins suggests that those burial containers may have been homemade; the others were manufactured locally or mass-produced. Nearly half the features included outer boxes, randomly distributed and apparently unrelated to unstable soils.

Birmingham, Bob (University of Wisconsin Waukesha)
[82] Ancient Effigy Mound Landscapes of North America
Between ca. A.D. 700 and 1100, Late Woodland people in the Upper Midwest of North America used the topography and other features of the natural landscape to create vast ceremonial landscapes consisting of thousands of earthen mounds sculpted into animals and animal spirits that mirrored their belief and clan-based social structures, similar to the beliefs and social systems of more recent Indian people, and that served an important role in mortuary ritual. It is proposed that these effigy mounds were living, ceremonial landscapes in the minds of the makers where ancestral animals and the supernatural were ritually brought back to life for protection, assistance, and maintenance of identity at places where the spirits are best evoked in a continuous cycle of death and rebirth of the earth and its people. This poster graphically demonstrates how three-dimensional maps of ancient cosmology were created with effigy mound landscapes in different parts of the region that vary in natural landscapes and with the nature of the animal and spirits that are imbued in these landscapes.

[128] Frontiers and Boundaries: A View from the Western Maya Lowlands
Frontiers or boundaries, aside from those imposed by unchanging physiographic structures, are commonly used archaeological constructs. They represent “snapshots” of societal structures cognitively employed to suggest some heuristic division. This snapshot is invigorated by adding the term “dynamic.” Complexity exists for not all aspects of a polity reflect the boundary or frontier construct in the same way or at the same time, as may erroneously be implied by reference to a material “complex” or inferred from horizontal lines on a chronology chart. In this brief paper, I call attention to how ceramic materials from the Late Classic Maya site of Palenque are being used to infer inter polity boundaries and how they varied according to political and social changes.

Bishop, Andrew (Arizona State University) and Kim Hill (Arizona State University)
[132] Firearms and Return Rates: A Reanalysis of the Proposed Relationship between Body Size and Prey Rank

The relationship between body size and energetic return rate for prey has been critically analyzed by anthropologists and archaeologists for decades. The ability to determine energetic return rates and prey ranks is essential to the use of the prey-choice model, however, these data can only be accurately obtained through direct observation. The idea that relative body size could serve as a proxy measurement for relative prey ranks has been a critical component of the application of optimal-foraging and prey-choice models to the archaeological record. This paper analyzes the validity and strength of the proposed positive correlation between body size and prey rank in modern ethnographic context, using return rate data collected through direct observation. The impact of firearms on diet breadth and prey rank is examined, and the relationship between prey size and prey rank is reconsidered in contexts which may better approximate ancestral human conditions. Alternative explanations are offered for the patterned shift in faunal assemblages from large bodied to small bodied game which appeal to life history and importance to diet rather than prey rank.

Bishop, Katelyn (University of California, Los Angeles)

[140] Early Formative Period Bird Exploitation at Paso de la Amada, Soconusco, Mexico

Bird remains form important parts of zooarchaeological assemblages that are sometimes overlooked in studies of emergent complexity. While they can answer questions regarding consumption, bird assemblages can also help reconstruct the use of animals for ritual purposes. This study examines Early Formative period (1800-1000 B.C.) bird exploitation and use at the site of Paso de la Amada in the Soconusco region of southern Mexico. The site exhibits evidence of early participation in what may be considered a pan-Mesoamerican set of ritual beliefs. It is thus a unique location to explore the hypothesis that, rather than simply factoring as components of a subsistence economy, birds and their byproducts contributed to ritual activities and played an increasing role in the accumulation of wealth. This study examines factors such as plumage color, locality and habitat of species, species diet, elemental selection, bone modification, intra-site distribution, and ritual deposition to ascertain for what non-dietary purposes the inhabitants of Paso de la Amada were hunting birds.

Biskowski, Martin (California State University, Sacramento)

[63] Staple Food Preparation at Teotihuacan

The rapid growth of Teotihuacan created subsistence problems common to urban systems. But Teotihuacan first encountered these problems without well-developed institutions and traditions of urban living, and the city consequently lacked access to solutions to subsistence problems which became common in later centuries. Tracking how Teotihuacanos solved these problems is fundamental to understanding life in the early city. A variety of evidence from grinding tools and other food preparation tools indicates a diverse range of subsistence strategies were employed within the early city. Many of these strategies apparently were organized around small social units whose economic activities bridged the gap between the capabilities of Teotihuacan’s nascent economic institutions and the subsistence needs of its inhabitants.

[216] Identifying Technological Variation between Early Mid-Holocene Social Groups in the Lower Tennessee Valley: The Use of Geometric Morphometrics in Projectile Point Shape Analysis

The Eva and Big Sandy sites are two of the most well-known shell bearing sites in the midcontinental US, but their respective histories are relatively poorly understood. Recently obtained radiocarbon dates from both sites indicate that they were contemporaneously occupied during the early centuries of the Mid-Holocene period between 8,900 and 8,200 cal yr B.P., and their early components are among the oldest dated Archaic shell-bearing deposits in the interior eastern United States. The early deposits at the two sites contained large numbers of Eva points, a large and highly recognizable chipped stone projectile point form. Based on the results of geometric morphometric analysis, a statistical technique for shape analysis capable of assessing minute, patterned morphological variation in groups of similarly-shaped objects, I argue that minute, patterned variation in the forms of Evas from the two sites suggests that Eva and Big Sandy were occupied during their initial periods of use by members of distinct social groups who, while not of wholly separate cultural traditions, nevertheless were different enough to have developed detectable variation in their manufacturing sequences.
Bisson, Michael (McGill University)

**Teaching Complexity and Ambiguity in an Introductory World Prehistory Course**
Teaching an introductory-level archaeology and world prehistory course at the university level is challenging because the instructor must balance the need for comprehensive coverage against the risk of superficiality that would impede student understanding of the discipline. This paper is a personal account of the use of an interactive role-playing laboratory exercise to teach archaeological field and laboratory methods, in the context of hypothesis testing. The interaction between theory and research design and the potential influence of the archaeologists’ intellectual history on interpretation are strongly emphasized. The topics of the exercise are the “Neanderthal problem” and the origins of complex cognition, interrelated issues which are subject to currently unresolved debate. This exercise has demonstrated that first-year students are capable of understanding and manipulating complex and occasionally conflicting data to produce an effective scientific argument. Although this is a successful pedagogical technique, the labor cost to the instructor and teaching assistants is very high.

Bjerregaard, Lena (Ethnologisches Museum, Berlin)

**The Diversity of Environments Preserving Non-Excavated Textiles in South America and in Europe.**
The best preserved, old, archaeological textiles are found in the dry deserts of Peru and Egypt. But the highland rainforest of Peru, the waterlogged bogs of Scandinavia, and Swiss lakes also contain well preserved textiles. Fragments of textiles or textile imprints are also sometimes preserved on metal objects, where all the rest of the textiles are gone. Different environments preserve different textiles. Funerary rites in some cases help the preservation of the textiles, and dyeing processes applied to the textiles during their creation can either preserve or damage the fibers. With examples from archaeological textiles excavated in South America and Europe this paper tries to define the local environments that will preserve some and destroy other fibers, and why and how these conditions interact with the different kinds of textiles.

**Redefining Tewa Basin Chronology in the Classic Period through the Examination of Tewa Biscuit Wares**
The Protohistoric-period Tewa culture history of the northern Rio Grande region, and specifically the Rio Chama watershed, is poorly understood. Although it is generally known that ancestral Tewa people depopulated their highland settlements and coalesced in Historic-period villages along the Rio Grande in the sixteenth century, the timing and catalysts of this move are debated, particularly pertaining to the effects of Spanish colonization and climate change. This project attempts to refine the typology of ancestral Tewa biscuit ware pottery to better date Late Classic period (A.D. 1500–1598) settlement and population movement in the Tewa homeland. I suggest that the current biscuit ware typology (Abiquiu Black-on-gray and Bandelier Black-on-gray) is chronologically too broad and does not capture the stylistic, technological, and temporal variability practiced by Tewa potters. I investigate the possibility of a third previously proposed and technologically discreet type (Cuyamungue Black-on-tan) that dates to the sixteenth century. My investigation will combine an attribute analysis (form, slip, pigment, design execution, paste, and temper) with a technological study (investigating firing dehydration, oxidation, and vitrification) to examine variation in biscuit ware pottery from the site of Sapawe’unige and help to resolve the history of a turbulent time in Tewa history.

**A Morphometric Approach to Characterizing Heterogeneity in Cranial Modification in the South-Central Peruvian Highlands**
An enduring debate in Andean bioarchaeology concerns the nature and meaning of intentional cranial vault modification (CVM). Traditionally, crania were characterized based on the modification technique used (boards or circumferential bindings) and the angle of the back of the head (erect or oblique). However, broad categories obscure the variability of head-shape within each group. Here, we attempt to characterize CVM variation quantitatively using 3D geometric morphometric techniques. Variation in CVM may speak to a type of ascribed identity that, in the Peruvian Andahuaylas region ca. AD 1150-1250, was associated with hardships including violence and disease. Eighty well-contextualized "normal" and "CVM" crania excavated at the Andahuaylan Chanka polity site of Cachi were assessed for patterns
of variation. The crania were scanned, and 12-18 landmarks were collected on 3D images to capture various aspects of cranial vault shape. The crania were then aligned using Generalized Procrustes Analysis, and Principal Components analyses were subsequently employed to highlight meaningful differences across crania for different landmark sets. The resulting variation among CVM crania along the principal components axes suggests a large amount of heterogeneity in circumferential CVM and points to a moderately standardized practice; head shape may signal a lineage-based or "ethnic-like" social identity.

When Did the Sun Go Down? Placing the Avondale Burial Place in Time.

Folk Cemeteries frequently are a challenge to assign to a place in time. Historical and family records for the Avondale Burial Place were limited and could only provide general temporal inferences. Surface decorations did not record death dates and most could not be associated with specific graves. Artifacts from within the graves were examined for temporal data. As a whole the cemetery could be dated to between 1820 and about 1930 within individual graves expressing narrower deposition dates. Conservative approaches to burial traditions by the community translated into material forms that exhibited long use periods; many graves therefore possessed broad deposition dates. The spatial distribution of dated graves in the cemetery reflected a pattern where later period graves were placed on the periphery of a core composed of potentially earlier deposited graves. Family clusters and pre-Emancipation era components of the cemetery were visible in the cemetery's temporal data.

Documenting, Sampling, and Conserving Complexly Stratified Rockshelter Deposits

In our ongoing investigation of Eagle Cave, a massive dry rockshelter in the Lower Pecos Canyonlands of southwest Texas, we are adapting new recording and sampling methods to tackle discontinuous, complexly stratified deposits over 3 m thick spanning over 9,000 years. The 1930s excavations at Eagle Cave by the Witte Museum, and 1960s excavations by University of Texas resulted in a long deep trench through the center of the site. Left open, the trench walls have collapsed, leaving small exposures of intact stratification in the upper deposits yet protecting the lower deposits. The focus of the earlier work was on recovering perishable artifacts and painted pebbles for museum display (1930s) and on establishing projectile point chronology (1960s) using gross stratigraphic zones. We aim to: 1) expose and stabilize intact deposits in discontinuous sections across the site; 2) use high-resolution Structure from Motion (SfM) 3D models to document small-scale vertical excavations following natural strata, some of which are quite thin, intermittent, and ephemerally exposed; 3) sample each layer to develop a fine-grained and tightly dated multidimensional record of rockshelter formation and use; and 4) backfill the trench and potholes to conserve the extant deposits for future generations.

“Empty” Spaces and Indigenous Visibility: Preliminary Research at Mission San Antonio de Padua

Although scholarly investigations into European colonization have surged in the last 20 years, research within California missions continues to be framed within the binary of colonizer/colonized. As the fundamental axis of identification, this dichotomy emphasizes the effects of European contact while obscuring the far more complicated conditions that colonial encounters produced. This has been partly exacerbated by archaeologists’ overemphasis of adobe architecture and interior spaces. While these kinds of excavations can provide insight into indigenous practice, they represent a small percentage of the larger mission community and one under the close scrutiny of priests and soldiers. To countervail this, preliminary research at Mission San Antonio de Padua (California) has employed a landscape approach to examine how exterior spaces were utilized and consider what roles these "empty" spaces played in indigenous identity formation. This paper presents preliminary artifact and soil analyses of materials collected from posthole transects dug in the summers of 2011 and 2012. By studying the experiences of those who lived outside of the church's walls, we are trying to open up traditional frameworks that have defined both identity and the spaces in which it is constructed in rigid and dichotomous ways.
Blair, Elliot (UC Berkeley)

[243] **Constellations of Practice at Mission Santa Catalina de Guale**

Situated learning theory has recently emerged in archaeology as a powerful way of exploring socio-material relationships. Among its many strengths is that by focusing on the “community of practice” as an analytic unit one can explore “groupness” without resorting to a priori categories of social identity. In this paper I embrace this benefit to explore the social landscape of Mission Santa Catalina de Guale, a 17th-century Spanish mission community (St. Catherines Island, GA). I employ two different datasets to explore past communities of practice: locally produced ceramics and glass trade beads. I explore local ceramic production communities of practice, examining how these operate at the neighborhood and household scale. Using glass beads recovered from the mission cemetery, I discuss the multiple communities of practice involved in their manufacture and distribution during the 17th century. By considering how beads that derive from different manufacturing communities are distributed, circulating within “local” communities of consumption, I reassemble social networks operating at a different scale than that of the ceramic production communities. I conclude by weaving together these multiple communities of practice from different material arenas, operating across practices of both production and consumption and at both a global and a local geo-spatial scale.

Blake, Elizabeth (McDonald Institute for Archaeological Research, University of Cambridge) and Ian Cross (Professor of Music and Science, Faculty of Music, University of Cambridge)

[122] **Sound and Music in Archaeological Contexts: The Lithoacoustics Project**

Sound is an important part of the human communicative toolkit. It provides information about the environments in which people live, and its production, perception, and socially ascribed meanings play a role in how people interact with each other. However, approaches to studying sound in the past remain underdeveloped in archaeology. In part this is due to the fact that there is no single discipline to which archaeologists can refer for information about sound and human behavior. There has also been a tendency to interpret the social values of sound in terms that are based upon those typically associated with urban and industrialized societies, and to focus on sound tools, or musical instruments, that are similar to well-known contemporary instrument types. These presumptions have tended to underpin the exploration and evaluation of social meaning in sound and in sound tools, and they are likely to have impeded the identification and interpretation of aurally significant artifacts. This paper presents the Lithoacoustics Project as a case study with scope for investigating and interpreting sound and sound tools in archaeological contexts by drawing upon multi-disciplinary and experimental approaches in the light of ethological, acoustical, psychological and anthropological evidence.

Blakeslee, Donald (Wichita State University)

[208] **An Experiment in Point Classification**

This presentation reports the design and results of an experiment in projectile point classification. The technique used is called stacked outlines, which allow an analyst to see both the modal form(s) and range of variation within a type. They are also useful for documenting the similarities and differences between types. I applied the technique to a sample of 500 contracting stem points, which are notorious for being difficult to classify. The results of the experiment show that 1) the points are representative of discrete types and 2) that types are consistent across large spatial distances, and that there is no significant variation through time within the types.

Blanton, Dennis (James Madison University)

[276] **Explaining Archaeological Variability among Sites of Early, Native-Spanish Encounter in the Southeast**

Interpretation of earliest Native-Spanish encounters in the Southeast is complicated by tremendous variability in many aspects of candidate sites including methods and contexts of recovery, and assemblage diversity and richness. The nature of that variability will be described, means of accommodating it outlined, and competing explanations of the behaviors that produced it evaluated. Beyond recovery methods, unique circumstances of initial European exploration were arguably the most prominent factor behind the pattern. A baseline for comparison is the Glass Site in south-central Georgia, a small, late prehistoric community that has recently yielded robust evidence of Native-Spanish interaction early in the sixteenth century.

Examining Landscape Transformations at Oévemanâhéno: The Use of Modern and Traditional Methods at an Early Reservation-Era Community along the Tongue River on the Northern Cheyenne Reservation

The Northern Cheyenne Reservation, located along the Tongue River in eastern Montana, was established in the early 20th century, at this time Northern Cheyenne were expected to move onto reservation land and begin the enculturation process into Euro-American society. To expedite this process, the Bureau of Indian Affairs (BIA) developed schools, agricultural facilities, churches and ranching opportunities. During July 2013, in partnership with the Institute on Ecosystems, Chief Dull Knife College, the Northern Cheyenne Tribe, and Montana State University-Billings City College, a University of Montana field crew traveled to Oévemanâhéno (Birney Day School Village, Montana, 24RB1064) to document, what is known amongst the Northern Cheyenne Tribe, as the most traditional community on the Northern Cheyenne Reservation. Methods such as archaeological survey, 3D digital laser scanning, photogrammetry, analysis of 1924 BIA records and ethnography were used to reconstruct the cabin locations and the landscape of historic Oévemanâhéno. This fieldwork is drawing attention to the ways in which colonialism altered—and continues to alter—the traditional, river-dependent economy and cultural landscape of this early-reservation-era community. It is through this lens that we can examine relatively sudden and dramatic landscape transformations yielding relevant information for land managers, researchers, and the general public.
object by altering color, luster, texture, and other physical properties. Skeuomorphs elicit revaluation of objects because a rank order of object value has been established. The scale of value created by skeuomorphs can also be extended from object to person by possession of objects along the scale of value to convey prestige distinctions through connotation and association.

[25] Tiwanaku’s Talking Heads: Unpacking the Meaning of Human Heads through Bioarchaeological and Archaeological Data
This paper draws together bioarchaeological and archaeological datasets to address the meaning of human heads in ancient Tiwanaku society ca. 500 to 1150 A.D. in the south central Andes. A bioarchaeological approach reveals that group or community identity was permanently embodied on the head during first years of life and this diacritical feature was perhaps involved in boundary maintenance between different groups, even while people moved between regions. Molding the child’s head appears to be an important element in assigning personhood to Tiwanaku individuals. The ontological primacy of the head as the locus of the embodied person suggested by the bioarchaeological data can also be seen in Tiwanaku art and iconography, where depictions of human figures focus almost exclusively on heads rather than faces or entire bodies. In this paper, we ask what the combined datasets on the meaning of heads in Tiwanaku society tell us about culturally specific notions of personhood, death, and social reproduction.

[23] Human Adaptation to High-Latitude Upland Landscapes in the Central Alaska Range
The central Alaska Range plays an important role in understanding prehistoric human adaptation to high-latitude upland landscapes. The goal of this research is to explain the timing, environmental context, and nature of initial human use of the central Alaska Range, and to explore how the environment and use of upland landscapes changed throughout prehistory from earliest use through the late Holocene. The spread of hunter-gatherers into upland landscapes in eastern Beringia during the late Pleistocene and Holocene required unique behavioral and corresponding lithic technological adjustments. To investigate these changes, we tested 13 previously unrecorded archaeological sites in the upper Susitna River basin in the central Alaska Range. We recovered lithic, faunal and geoarchaeological data, and collected peat cores from four peat bogs for palynological and macrobotanical analysis. These archaeological, geomorphological, and paleoecological data are used to explore variation in lithic technology and subsistence activities, and how these relate to environmental shifts and upland land use.

[78] Landscape Reconstruction of the Fort Missoula Historic Dump and Grant Kohrs Ranch National Park
Archaeological case studies from both prehistoric and historic periods along the Clark Fork and Bitterroot Rivers can be used as microcosms for understanding questions related to landscape transformations and climate change throughout the arid American West and beyond. This research will work to integrate
historic General Land Office (GLO) Surveys, archaeological site records, paleoecological data, Traditional Ecological Knowledge (TEK), modern ecological data, and modern plant surveys to develop environmental reconstructions for the area landscapes encompassing the Fort Missoula Historic Dump and Grant Kohrs Historic Ranch. Multiple lines of proxy data recovered during field work during the summer 2013 field season and historical research will provide a backdrop and temporal scale for examining coupled natural and human ecosystems and will explore the ways in which anthropogenic alterations have influenced ecosystem structure, function, and transformations in the region.

*A General Spatial Reconstruction of Potential Maize Paleoproductivity, AD 600–2000*

In the decades since the pioneering maize paleoproductivity work of Burns and Van West, which formed the foundation of the VEP I paleoproductivity model, archaeologists have learned a lot about maize agronomy. Maize has specific requirements for number of frost-free days and accumulated heat. Precipitation is not only essential for growth and maturation, but also for nutrient fixation and de-alkalinization. Ancestral varieties of maize vary in their temperature and precipitation requirements and these constraints vary markedly across the Southwest landscape and through time. Ancestral Pueblo farmers unquestionably had a nuanced understanding of these demands and developed generally successful strategies to meet them. Here, we present a new model for potential maize productivity that can be applied to any study region. We use local and regional tree-ring and pollen records to generate spatial retrodictions of growing-season temperature and winter-summer precipitation across the two VEP study areas. Our reconstruction accounts for both high- and low-frequency climate regimes, as well as for highly local topographical effects such as cold-air drainage. We then transform these retrodictions into potential paleoproductivity for farming technologies ranging from the rain-fed agriculture of the NSJ region to the diverse runoff- and floodplain-irrigation strategies employed in the NRG.

*Empty Units Are Filled with Data: An Example of Investigating Site Formation Processes*

Utilizing non-cultural data to inform on cultural aspects of archaeological sites is not new, especially in sites with complex site formation histories or sites under intense scrutiny. However, we suggest that such rigorous research methodologies should be applied more often. Non-cultural data can be invaluable for independent analysis of a site. To illustrate the benefits of such research programs, we present data from non-cultural excavations at the Mountaineer site, a high elevation Folsom encampment. The Mountaineer site was suggested to contain multiple Folsom-aged structures with varied activity areas. To test whether the structures were, in fact, structures, two non-cultural excavations were carried out. Using data from the non-cultural areas, the research team was able to demonstrate that the structures were culturally derived. Additionally, the non-cultural data also revealed information on the bone, daub, charcoal, and opal CT assemblages from the site.

*Maya Animal Exploitation during the Middle Preclassic Period: Prey Choice, Habitat Use and Transport Decisions at Pacbitun, Belize*

This paper examines animal resource exploitation during the Middle Preclassic period (900–300 B.C.) at the ancient Maya site of Pacbitun, Belize. Diet breadth, habitat use, and carcass transport patterns are interpreted using the central place forager prey choice model as a framework. White-tailed deer appear to have been the prey most frequently taken by the Maya of Pacbitun, followed by other lower-ranked artiodactyls. A variety of less profitable prey were sometimes included in the diet. The analysis suggests the procurement of resources from terrestrial habitats at short distances from the site, and the occasional
use of exotic resources. Complete carcasses of large game appear to have been frequently transported to the site, where they were exploited for their meat and marrow. Comparisons with other Middle Preclassic faunal assemblages indicate significant differences in terms of taxonomic composition.

**Sourcing Rhyolites in New Hampshire Paleoindian Sites with Greater Precision Using a Portable X-Ray Fluorescence Device**  

The availability of portable X-ray fluorescence (XRF) devices, such as the Bruker Tracer III-SD XRF spectrometer, has made characterization of stone tool sources such as obsidians, substantially more effective and efficient. Two sources of visually similar yet geologically distinct rhyolites have been intensely sampled and shown to be geochemically distinct according to a suite of trace elements. These are the Mt. Jasper lithic source in Berlin, NH and the rhyolites found in the glacial till of Jefferson NH, 30 kilometers distant. Analysis using this technology of tools and debitage from Early and Middle Paleoindian sites in Randolph, Jefferson and other sites has revised our approach to visual identification of rhyolite varieties and revealed unexpected distributions and patterns of usage.

**Open(ing) Archaeology: A Model for Digital Engagement**  

This paper begins with a brief introduction of the Open Authority and Co-Creation models and explores their role in altering and revolutionizing archaeological practice. The focus then shifts to a discussion of engagement methods that archaeologists are currently utilizing on the web, including blogging, crowdfunding, and social media and evaluates their success as co-creative projects. These methods are compared with co-creative methods that are being utilized by other scientific disciplines, in particular, crowdsourcing. This paper concludes by considering 1) the obstacles and challenges facing the implementation of archaeological co-creative projects that are web based and 2) best practices for digital co-creative engagement identified from successful projects.

**Ancient DNA from Early Human Burials in the Argentine Puna: Insights into Burial Practices and South American Population History**  

Although the earliest archaeological sites in South America date to the late Pleistocene, little is known about the genetic makeup or mortuary behavior of early hunter-gatherer populations in South America. To help shed light on the burial practices of these hunter-gatherers, as well as the early population history of this region, we extracted ancient DNA from the remains of 13 individuals excavated from early and mid-Holocene archaeological sites in the southern Argentine Puna. These remains are from four locations in the Antofagasta de la Sierra region of northwestern Argentina, and date between 9200 and 3200 YBP. We sequenced 372 base pairs of the first hypervariable region of the mitochondrial DNA to define maternally-inherited genetic lineages, and analyzed a length dimorphism in the amelogenin gene to investigate the sex of each individual. We found that maternally related individuals were sometimes buried together, and several individuals exhibited a mtDNA lineage that is rare in indigenous American populations today. Our results shed light on the early population history of this region and help elucidate the genetic affinities between the prehistoric inhabitants of the Puna and other regions in South America.

The Chincha Mortuary Tradition in the Upper Chincha Valley, Peru

The upper Chincha Valley, located on the Peruvian south coast, is marked by chullpas, above-ground funerary towers, likely dating to the Late Intermediate Period (A.D. 1100-1476) and Late Horizon (A.D. 1476-1532). Previous research interprets chullpas within theoretical frameworks built around social organization, ancestral veneration, and territoriality. These investigations largely concentrate on chullpas constructed in the highlands of Peru, Bolivia, and Chile. Here, we present the mortuary data collected during the 2013 field season. We report a high degree of chullpa construction (over 500 tombs) with associated patios and plazas and several mortuary finds including burned human remains and reed posts with human vertebrae. We preliminarily define a consistent mortuary tradition in the upper Chincha Valley characterized by the pervasive construction of chullpas and discuss the implications for secondary burial activity and ancestral veneration rituals.

Boomgarden, Shannon (University of Utah)

Experimental Maize Farming in Range Creek Canyon, Utah: Year One

It is clear from the archaeological and isotopic evidence found in Range Creek Canyon, Utah, that maize agriculture was a significant part of the Fremont diet during the seemingly short prehistoric occupation around 1050 A.D. Of the nearly 450 sites recorded in the canyon, there are over 100 storage structures (granaries and cists), 116 sites with ground stone, and maize has been recorded and collected throughout the canyon. We hypothesize that given the arid conditions, precipitation alone would not have been sufficient to successfully grow a significant amount of maize. An experiment designed to look at the costs and benefits of irrigation and the amount of water necessary to produce maize in Range Creek was carried out during the 2013 growing season. Four experimental plots were planted. One plot was not watered. Three plots were watered using irrigation from the creek on three different watering schedules: once per week, twice per week, and "as needed." The maize selected for the experimental plots was Onaveno, a flint variety from the Rio Mayo in Sonora, Mexico. This poster will discuss the process and results of the experiment and ideas for future farming experiments in Range Creek Canyon.

Borau, Laetitia (Université Paris 4 Sorbonne. Laboratoire TRACES)

Access to water has always been an essential factor for societies, especially when they settle on hilltops. Primarily intended for daily consumption, water requires the development of specific techniques designed to channel and store it. It assumes a strong symbolic value attested by different types of remains. The analysis of hydraulic structures demonstrates the adaptation of populations to their environment, but also enables us to understand their social practices: they are the result of technical or ritual gestures. According to this approach, the Gallic oppidum of Bibracte, the most important in Gaul, is a particularly rich field of study. It was precisely in this high-up site where Caesar chose to take his winter quarters in 52 B.C. Our recent studies have identified 125 hydraulic structures and demonstrate, for the first time, the presence of large collective catchment basins and reservoirs. These meeting places are also the focus of certain religious practices. This study reveals the existence of strong local traditions particularly in the use of wood and clay in the making of hydraulic structures. The comparison of these constructions with the hydrological resources and environmental context give a new perspective on the management of water in hilltop settlements.

So If All Your Friends Jumped Off a Cliff [Polychrome], You Would Jump Too? Modeling Precolonial Participation and Resistance to the Salado Social Movement

In this paper, we present a model that cross-cuts the "great divide" between precolonial and colonial inquiries. Our study uses data about the prehispanic depopulation of northeastern Arizona and subsequent movement of those groups into populated areas in southern Arizona. An emergent socioreligious movement, termed “Salado”, resulted from this culture contact. It incorporated new consumptive practices, including specialized production of polychrome ceramics and large-scale feasting. The adoption of new consumption practices is an agentive process where simple knowledge of “foreign”
objects is not sufficient to explain their adoption. We present a model in which knowledge and attitude interact to determine the integration of these social practices. A negative attitude may result in active resistance to those “foreign” objects and practices. To recognize resistance without colonial period documents, we integrate inferential tools developed by postcolonial researchers examining historically neglected groups with a formal social network model in which knowledge and adoption of “foreign” objects are considered separate historical events. Attitude, pivotal to the model, is multivocal and governs future interactions. This model demonstrates how and why consumptive practices are affected by culture contact and demonstrates how archaeological/historical data can be operationalized to approach the adoption of “foreign” objects and practices.

[149] Convergence and Divergence as Problems of Explanation in Land-Use Histories: Two Mexican Examples

Similar results that arise from different processes and causes (convergence or equipfinality) and different results that arise from similar processes and causes (divergence) are two common problems of explanation in any historical science. Two cases rooted in geoarchaeological fieldwork in highland Mexico exemplify such problems. Marked changes in the pace and style of sedimentation are observable at ca. A.D. 1000 in the Mixteca Alta. Potential proximate causes include changed runoff, sediment delivery from slopes, adjustments of stream gradient, or channel form. Each can hint in turn at a plethora of ultimate causes in realms such as climate, demography, agriculture, or warfare. Dramatic population growth is observable between ca. 500–100 B.C. and A.D. 1300–1500 in Tlaxcala. The first time interval coincides with widespread degradation, the second with widespread improvement of farmland. Chronological refinements that would allow in themselves to choose between alternative explanations are not in sight. The solution may lie instead in contrasting fieldwork at different spatial scales, and greater attention to the historical antecedents of geomorphic systems and farming traditions.

[307] The Monterrey Shipwreck Project: Preliminary Results

The 2013 Monterrey Shipwreck Project recovered more than 60 artifacts, a dozen sediment samples, and a live anemone as a means to deduce information not just about the ship itself and those aboard, but also to learn about the interaction between the wreck and its environment. Examples of dinnerware, navigational tools, medicinal supplies, personal items, and weapons were collected to supplement video and photographic documentation of Monterrey Shipwreck A. As part of ongoing research, these data will be compared to video imagery collected on the neighboring shipwrecks, now known as Monterrey Wrecks B and C, and other archaeological sites and historic collections in order to help refine the date of the shipwreck and determine cultural affiliations. The sediment and biological samples further our current understanding of the interplay between the natural environment and a complex foreign object and show how one influences the other at such great water depths. This paper will present the preliminary results to date and share what has been discovered about the shipwrecks and related ecosystem.

Borgstede, Gregory

[296] Archaeology Should Be Diplomatic

In this presentation I examine the implications of four/five-field holistic anthropological training for diplomacy and international relations (IR). I approach the topic through the framework of international debate concerning the intersection of trafficking in cultural property (TICP) and transnational organized crime (TOC). I argue that the TICP TOC issue has an important diplomatic component, including national and international consensus-building and policy setting. The interplay of these aspects centers on compromises that must be agreed upon among stakeholders from differing sociocultural standpoints. I contend that the cultural standpoints affect research, analysis, mutual comprehension, and public presentation of national positions, and I attempt to demonstrate the efficacy of holistic anthropological training to analyzing and understanding the role of diplomacy in bi- and multi-lateral settings. I conclude that TICP TOC policy—its negotiation, setting, and presentation—is best understood through the tools of holistic anthropological study.

[278] LGM Marmot Hunting in the Dinaric Alps

The Balkans is often considered a refugium of European foragers during the Last Glacial Maximum (LGM), along with the possible importance of the northern Adriatic Plain as an area that might have seen the concentration of resources and human groups. Yet, the topography of large areas of the western Balkans is characterized by extensive mountain ranges known as the Dinaric Alps with many high altitude locations. The character of human occupation before, during and after the LGM in this region is poorly understood if compared with the Italian Alps and Prealps, where research to date has provided more detailed information about human responses to changing climatic conditions in the course of the late Pleistocene and early Holocene. Our research in the mountainous areas of western Montenegro identified marmot hunting dated to c. 24–23 ka cal B.P. and suggests the use of higher altitude locations during the LGM. Our paper compares this specialized focus on marmot hunting in the southern Dinaric Alps to several similar sites identified in the Alpine region but dated to the Epigravettian period.

[201] Climate Change, Availability of Territory, and the Late Pleistocene Human Exploration of Ultima Esperanza, South Chile

A complex set of swiftly changing climatic and environmental conditions was taking place at the time of the first human exploration of Ultima Esperanza, Patagonia, Chile. The retreat of Pleistocene glaciation and the formation of a proglacial lake created adequate basic conditions for human colonization. Volcanic activity, climatic oscillations, and concomitant floristic changes added a degree of uncertainty to hunter/gatherers prospects for adaptive success. The archaeological evidence indicates that the first archaeological evidences were deposited sometime between 11.5 and 11.0 ka B.P. We will report new archaeological evidence and will discuss its relevance to understand the peopling of the region.

[67] Fashion or Social Meaning? Analyzing Change in Monumental Burials of Prehistoric Eastern Arabia

This work analyzes change in prehistoric funerary structures and related material culture of Early Bronze Age eastern Arabia (Northern Oman and UAE, 3100-2000 B.C.) from the perspective of cultural evolutionary theory (Cavalli-Sforza and Feldman, 1981; Boyd and Richerson, 1985). By observing decorative and structural elements in monumental tombs and pottery, new hypotheses about the underlying mechanisms of cultural transmission can be explored. The main objective is to transcend the traditional dichotomy between early and late tomb types by creating an explanatory framework that looks at diachronic variation for inferring cultural processes. The research develops a new systematic description of burials and ceramics. Diversity measures are used to investigate the role played by human interaction/isolation and demography in determining adoption, replication, systematic preference and persistence of the examined cultural variants. Results confirm that specific mechanisms are at work in different moments of time, for both tombs and ceramics. By starting to research the processes underlying structural change, this work allows for a reassessment of the current interpretation of prehistoric funerary practices, and generates new hypotheses on the movement of people and ideas in a still largely unexplored context.

[172] A Geoarchaeological Investigation of the Provenance of Chert Artifacts from the Prehistoric Wansack Site (36ME61) in Western Pennsylvania

Wansack (36ME61) is a multicomponent, prehistoric site located in western Pennsylvania (Mercer County) just east of the Ohio border. Four seasons of excavation (1974-1977) yielded ample evidence of occupation spanning the Archaic, Woodland, and Late Prehistoric periods. The present study analyses the patterns of raw material procurement as seen through the lithic artifacts collected from Wansack. The primary method utilized to do this is X-ray fluorescence spectrometry (XRF). Samples of chert from the
Flint Ridge, Upper Mercer, and Sky Hill outcrops provide a baseline for source types found in close proximity to Wansack. The elemental composition of source specimens is compared to that of artifacts recovered from Wansack to determine the point of origin of the latter. Flakes are tested from all stratigraphic levels of occupation, as well as across the site from each period. This study focuses on what the patterns of raw material procurement at Wansack can show about the changing dynamics of mobility, economic structures, and trading relationships from the Archaic through the Late Prehistoric period in the upper Ohio River drainage.

Boswell, Alicia (UCSD)

A Politically Marginal yet Essential Landscape: Late Andean Prehistory in the Yunga of the Moche Valley, Peru

Populations residing in the yunga ecological niche (500-2300 masl) on the west side of the Andes have been considered minor players in Andean prehistory. Living in a politically marginal zone between coastal and highland polities, yunga populations inhabiting the tributary valleys of coastal river valleys had constant interaction with coastal and highland polities whose exchange routes passed through the yunga. Additionally the yunga ecological niche produced prestige resources that were essential for the political economies of neighboring polities requiring Andean polities to interact with yunga residents. This paper presents results from archaeological excavations at Cerro Huancha, the largest archaeological site in the Sinsicap Valley, a tributary of the Moche River. This is the first archaeological excavation to take place in the Sinsicap Valley and presents new information about yunga residents’ local history during Late Andean period. In particular, we highlight the role of the yunga landscape in the formation of a local, yunga identity vis-a-vis the imperial Chimú and Inka polities.

Dreaming with the Ancestors: Black Seminole Women in Texas and Mexico

Although Black Seminole culture is interwoven with strands of other cultural influences, the resilience of African-derived customs and traditions among members of the group is examined in this paper. The prominent role of Black Seminole women in these cultural retentions is explored through historical documents, archival records, archaeological input, and descendant interviews. African-derived expressive forms such as dream reading to prognosticate the future, call and response oratory, and the ring dance persisted in the Black Seminole community as they wound their way through diasporic journeys, conflicts, wars, and relocations from Florida to Mexico and Texas. A profound respect for the ancestors, a defining feature of African-derived traditions, continued to resonate in funeral and burial traditions. African-derived naming conventions and a genealogical knowledge of ancestors sustained a collection of stories and events centered on historical events that anchored Black Seminoles in their identity—a landscape of kinship ties both culturally and genealogical defined.

Boudreaux, Sarah Nicole (University of Texas at San Antonio)

Life on the Edge: Models of Maya Community Formation and Development near the Dos Hombres Site Core

A vast amount of the Programme for Belize Archaeological Project permit area is unexplored terrain. As a result, the location, number, and size of ancient settlements are unknown, and the relationship between settlements is not well understood. Projects such as the Dos Hombres to Gran Cacao Archaeological Project (DH2GC) are trying to create a detailed picture of the PFABP area by way of an interdisciplinary inquiry including: archaeological, ecological, and geoarchaeological survey efforts. Over the past 5 years, a significant amount of settlement data has been collected within the DH2GC project boundaries. This paper analyzes the first 1 kilometer of the settlement, excavation, and ecological information in relationship with the site center of Dos Hombres. To create a more convincing settlement analysis, data from previous settlement studies around the Dos Hombres area are considered. This analysis will include size of residential groups, environmental setting, and ceramic data to understand community development, correlation with the environment, and temporal variation between community groups. The paper will conclude by offering future directions of research for the DH2GC project.

[327] The Use of Public Space within the Mississippian Center at Town Creek, North Carolina

Investigations of public spaces such as earthen mounds, plazas, and distinctive buildings have figured prominently in the study of Mississippian societies in the southeastern United States. Mississippian public spaces were the loci of a wide variety of activities that ranged from the domestic to the esoteric and from the mundane to the spectacular. Recent studies have demonstrated the variability that existed among public spaces within the same community, and others have considered how public spaces were used through time. This paper will compare several public contexts at the Town Creek site, a small Mississippian civic-ceremonial center in central North Carolina. The analysis of architecture, ceramic vessels, faunal remains, and other artifacts suggests that some of Town Creek’s public spaces were venues both for social integration through participation in communal events and for activities that may have emphasized social differences because they were more exclusive in nature. An association between these different kinds of activities and public spaces appears to have persisted throughout the center’s existence despite significant changes in other aspects of community life that included the construction of a platform mound and a substantial decrease in population.

[113] Faunal Circulation in Three Chacoan Great House Communities

This paper explores the intra- and inter-community circulation of fauna in three Chaco-era (ca. AD 1050-1130) great house communities in the Southern Cibola region of west-central New Mexico. In particular, we focus on ritual activities within the great house communities of Cox Ranch Pueblo, Cerro Pomo, and Largo Gap to explore intra-site subsistence and feasting trends in the larger Cibolan region. Based on the ethnographic record, many southwestern fauna were either hunted communally or individually for prestige purposes. Thus, the distribution of these animal goods throughout the communities helps indicate how different households interacted with the sites’ larger provisioning and ritual activities. By correlating social hierarchies and leadership strategies with ritual feasting activities, this paper explores how commonly utilized models of feasting dynamics in the Southwest articulate with models of centralized authority during the Chacoan era. Because feasting activities are generally considered either aggrandizing or integrative, the nature of feasting indicates how residents of these sites were utilizing Chacoan symbolism to legitimize their authority.

[315] Phylogenetic Analysis of Eastern Paleoindian Fluted Point Forms

Fluted projectile points dating to the Paleoindian period (ca. 13000–11000 cal BP) occur in a remarkable diversity of forms in eastern North America. However, because few of these specimens have been recovered from well-dated contexts, there remains much to learn about the spatial and temporal relationships of these point forms. Here, we use cladistics to analyze a large (n > 2500) sample of point forms from the East to pose testable hypotheses regarding geographical and phylogenetic relationships.

[109] Middle and Later Stone Age Occupations in the Modder River Valley, South Africa

Alluvial depositional records are rare in the interior of southern African but such sequences can provide critical information on human activities and paleoenvironmental contexts. Here we report on Middle Stone Age (MSA) and Later Stone Age (LSA) occupations in the Modder River valley. Four terraces have been identified with the oldest terrace, dating to the Middle Pleistocene, containing fossilized faunal remains and occasional artifacts. Numerous MSA and LSA locales were documented in a Late Pleistocene terrace that span the last 120k years. Faunal remains occur throughout the terrace deposits. Isolated Equus capensis, Megalotragus priscus and Damaliscus niro partially articulated skeletons were possibly associated with a significant drought, while in an upper unit of the same terrace Robberg occupants processed remains of plains game, such as Connochaetes gnou, Megalotragus priscus, Equus capensis and Phacochoerus sp. Stable isotope and phytolith results indicate widespread C3 plant environments
except for a brief period in the Late Pleistocene at the LGM when there is a marked shift to C4 plant communities. These results provide new information on Late Pleistocene climatic fluctuations in the grassland biome, the dual nature of wetland and open plains Florisian faunal species, and modern human adaptations in the interior grassveld.

[296] Archaeology Should Be Bioarchaeology (or Should It?)
At the 2011 SAA meetings, I participated in a forum called “The Future of Bioarchaeology,” held in honor of Fryxell Award winner Jane Buikstra. As we conversed, I was struck by how many of us continue to experience the same challenges that I had faced in graduate school: when it came to funding, publications, and the job search bioarchaeologists are at a disadvantage compared to peers who specialize in one anthropological subfield. The archaeologists who review our grant and job applications think we hew too closely to biological anthropology, while the biological anthropologists who review them think the reverse, leaving us in limbo and often without jobs or funding. But this is not cause for despair: I believe that the segregation of bioarchaeology between the four subfields is generational. Namely, the mentorship that we received is qualitatively different from the training that we are giving our own students. To test this hypothesis, I have created an online survey that is designed to assess bioarchaeology’s integration in the categories of training, teaching, research, funding, publications, and mentoring. I anticipate that the results will provide important insights into the current state of the discipline and lay the groundwork for new cross-subfield initiatives.

Bouwman, Abigail (University of Zurich)  
[291] The Different Aspects of aDNA in Establishing Kinship
Kinship can be defined in any manner of ways. In contemporary terms, it can be defined as close familial relationship, kinship via extended family group, or even relationship at the clan or tribal level. In a temporal sense, too, people can feel they have a kinship with direct ancestors or with a population. Genetics can identify only the genetic kinship of a group of people, not the sociological kinship. By looking at genetic markers, such as the HVRI in mtDNA or Y-chromosomal markers we can identify individuals with a maternal or paternal link, either in contemporary individuals, or over period of time. Here I will present two case studies, which exemplify two aspects of genetic kinship identification. Firstly, the mtDNA similarities and differences between individuals buried within Mycenae Grave circle B. Here, identical mtDNA sequences within two individuals of the same age buried within a short space of time indicate that either siblings or maternal cousins were buried together. Secondly, I examine the Y-chromosomal similarities and differences between a 17th-century individual and his purported descendants. Here, differences between the sequences cannot exclude or confirm ancestry because of the higher rate of mutation in non-autosomal DNA.

Recent research of Recuay materials, iconography, and architecture indicates a marked increase in warfare during the Early Intermediate Period of the highland Andes of Ancash, Peru (1-700 C.E.). Archaeologists have identified defensive trenches, fortified walls, and strategic site positioning at many individual Recuay community sites, a pattern which stands in sharp contrast to the character and location of village centers in the preceding Formative Period (1800-200 B.C.E.). This poster presents GIS viewshed and cost-path analyses to investigate trends in less physical elements of defensive constructions: visibility and accessibility. We will compare cumulative and individual viewsheds and the general accessibility of Early Horizon and Early Intermediate Period sites in highland Ancash to contribute a broader, regional perspective to our understanding of increasing warfare during this cultural transition.
Bowler, John (University of Mississippi)

**[52] Water Management at Cahal Pech**

Water management was a crucial factor in ancient Maya life and agricultural production. With distinct wet and dry seasons, obtaining water in the Maya area during times of drought and managing it during times of flooding was a major issue in Maya society. Recent water management research has focused on artificial catchment features such as reservoirs, along with natural features including streams and bodies of water. New insight into water retention features such as dams has shed light on a previously understudied aspect of Maya water management. This paper adds to the discussion by examining how the Maya managed water at the site of Cahal Pech in the Cayo District of Belize. Through excavations of a small Maya dam, along with a GIS analysis focusing on spatial and topographical data, this paper presents a hydrological model for Cahal Pech and the surrounding area.

Bowser, Brenda (CSU Fullerton)

Jochim’s seminal work in human behavioral ecology brought focus to people’s foraging behaviors as thoughtful, strategic, and flexible in response to ecological and social conditions. These are adaptive behaviors with fitness consequences. Jochim and his students and colleagues have extended those ideas to understand the transitions from mobile foraging to sedentism, social complexity, and agriculture. This study focuses on the strategies women use to acquire individual plant varieties and increase the richness of their gardens in a horticultural foraging society, based on ethnographic data. Potential benefits of garden richness include differential resistance to disease and insect predation, differential yield in current vs. future garden sites, and variable yields in different soils and micro-environmental contexts. Women increase the richness of their manioc gardens and their status by sharing garden resources strategically, and reproductive benefits accrue to high status women. Specifically, women develop networks of economic and political cooperation through which they share plant propagules, which positions some women as gatekeepers in the flow of plant resources within and between coalitions in a multi-ethnic community. These are significant ties that bind kin and non-kin together into networks of cooperative economic relationships, which are embedded in coalitional structures.

Boyce, Ian (Trent University)

**[43] Copper Bells in the Southwest: Evaluating the Prestige Goods Model**

Archaeologists are increasingly interested in trade and interaction between the Southwest United States and Mesoamerica. Copper bells, probably from West Mexico, have been recovered from sites throughout the American Southwest. Although archaeologists have compiled lists of the distribution of these artifacts, few have made an effort to understand their cultural significance. The artifacts have been lumped, somewhat unceremoniously, into the category of “prestige goods.” This poster will examine the cultural significance of Mesoamerican copper bells in the American Southwest. The temporal and geographical distribution of copper bells as well as their archaeological provenience will be examined. Whether the prestige goods model is an appropriate fit for these artifacts will then be evaluated. If this model is not found to be applicable, the possible economic, social, or ideological roles copper bells could have played in Southwest societies will be considered.

Boyd, Brian

**[22] Making Containers Visible in the Prehistoric Levant**

Archaeology has developed a fairly sophisticated understanding of “presence” in the literal sense of “things being there”, and in its recent theoretical encounter with materialities and their varied manifestations (including the expression of immaterial ideals). Given that the greater part of human history (prehistory) is materially absent, invisible, intangible, it might follow that prehistory should have something to offer the study of the intangible that is original and interesting. I will use the example of “invisible” containers, and the concept of containment, specifically in the later prehistoric Levant as a starting point for these explorations. Both plant and animal resources relating to containers will be considered.

Boyd, Carolyn (SHUMLA/Texas State University)
[156] Layers of Meaning: Stratigraphic Analysis of a Pictorial Narrative in the Lower Pecos Canyonlands of Texas

Description of individual figures at rock art sites provides data for inter- and intra-site patterning. Through documentation and analysis of the sequential ordering of those figures, as well as their stratigraphic relationships, researchers can gain insights into the artistic and cognitive processes that led to the creation of the panel. In this paper, I present the results of an analysis of the White Shaman rock art panel located in the Lower Pecos Canyonlands of southwest Texas. The panel spans 8 meters in length and 4 meters in height and contains more than 100 Pecos River style images dating to the Late Archaic (3,000 to 1,500 years ago). Through stratigraphic analysis of these pictographs using a Dino Lite handheld microscope, the development of Harris matrices, and production of layered illustrations using Adobe Photoshop, I have determined the strict order in which the colors were applied and the stratigraphic relationships between figures. This analysis demonstrates that the panel is a planned composition with rules governing not only the portrayal of symbolic forms, but also the sequencing of colors. Complex images painted in black, red, yellow, and white were woven together at the White Shaman site to form an intricate pictorial narrative.

[147] Delimiting the San Bernabé Mission and Determining Its Broader Context within the Site of Tayasal

Four seasons of fieldwork at the site of Tayasal, consisting of excavation and extensive mapping using a total transit station, managed, among other things, to locate and define the limits of the San Bernabé mission there. Placed amidst the Postclassic Maya community living at Tayasal at the time of Spanish conquest of the region, the Mission served as the local face of Spanish social control and dominance in that early Colonial era. The fieldwork performed during these recent seasons has served to enlighten the continuity and change in cultural attributes such as ritual and land use among the population there from the Middle Postclassic (A.D.1200 to 1400) through the ensuing Late Postclassic and Contact eras, and onward to the Colonial Era that started in 1697. Furthermore, the excavations have instigated a refinement of the ceramic sequence of the region, with implications for its overall chronology, while the use of current mapping technology on the ground and in the lab has allowed for detailed new maps to be produced of large areas of the site, including the new discoveries that have been made.

Bradley, Robert (University of Texas, Pan-American)

[192] Aquatic Imagery in Moche Art and Culture

This presentation scrutinizes the harvesting, cooking, and consumption of a species of Trichomycteriidae catfish in two traditional communities located on Peru’s North Coast. The information gleaned from this ethnographic study is then applied to Moche artistic representations for this creature. This particular species of Trichomycteriidae catfish has been enigmatically named life and even though the word was borrowed from English the pronunciation is Spanish. Life is likely a reference to this freshwater fish’s ability to go into a type of status when the coastal rivers, emanating from the highlands, dry up. When the rivers re-hydrate, the catfish seemingly comes back to life. Stylized images of life are prevalent in the tomb and on the body of recently discovered Moche burial: the Señora de Cao. These icons take on profound significance when associated with this tomb because of the catfish’s ability to reincarnate. But another interpretation of life symbolism is possible. The Trichomycteriidae family of South American catfish is also parasitic. Perhaps then, Moche iconographic representations of this catfish reference prisoner sacrifice and bloodletting, both practices being widespread in Moche culture.
Bradley, Bruce (University of Exeter)  
[318] A Genealogy of Late Pleistocene Flaked Stone Artifact Assemblages: An Interactive Exercise  
Flaked stone artifact assemblages are used to infer historical relationships through time and space. This is especially important when interpreting the highly variable evidence of the peopling of the Americas. Typological approaches have dominated but technological, tool use and stylistic insights have added greatly in the past several decades. Most efforts have been made by individual scholars. This poster is designed to take the process of historical relationships forward by soliciting input from those willing to collaborate on a communal effort. A proposed ‘phylogeny’ of flaked stone assemblages is presented that is designed to be modified. The poster uses images of projectile points and bifaces as proxies for whole TECHNOLOGICAL systems and their historical connections. Participants in the effort are asked to mark up the poster, making additions, deletions and corrections and will be asked to ‘own’ their input by it being photographed and recorded as theirs. Both evidence-based and subjective ideas are accepted. It is unclear what the outcome(s) of this exercise will be, they may include a “lithiwiki” that will be posted on the web for continued interaction resulting in various possible phylogenies that can be updated and refined as new evidence and insights are submitted.

Brady, James (Cal State L.A.)  
[292] Opening a New Vista on Sacred Landscape in Northern Belize: A Celebration of One Aspect of Leslie Shaw’s Research  
Smith and Schreiber, in their review of New World archaeology, state, “For the Classic Maya, studies of sacred landscapes are dominated by research on caves.” Cave archaeology, however, is extremely underdeveloped in northern Belize because the area’s soft dolomitic limestone does not support the formation of large caves that might have attracted archaeological attention. For this reason, it is not until recently that archaeologists have begun to consider the possibility that small subterranean chambers might have played an important role in the ancient sacred landscape. King and Shaw were among the first to raise the possibility. Their observations led to a field study of Spider Cave at the site of Maax Na, which was the first detailed cave documentation in northern Belize. The study confirmed that a shrine in the central plaza was built in relation to the cave with the discovery of a blocked passage that surfaced near the doorway to the shrine. More recently, a second field investigation by the Rio Bravo Archaeological Project has documented another cave located in the midst of public architecture. These discoveries open exciting possibilities for more extensive landscape studies.

Brady, Jana  
[172] Revealing Prehistoric Connecticut: A GIS Analysis of Archaic Sites in New Haven County  
A GIS platform was created to help with site analysis and data management of over 6000 lithic artifacts recovered in ten field seasons of excavations at the West Rock Nature Center-1 (WRNC-1) site in New Haven, Connecticut. The WRNC-1 site is located near a traprock portion of the Metacomet Ridge, which extends to the Massachusetts-Vermont border, and it serves as the setting for a field school for students at Southern Connecticut State University to learn archaeological methods under the direction of Michael J. Rogers. The lithic assemblage found at the site indicates that the area was used as a seasonal camp approximately 6000-3000 B.P., coinciding with the Late and Terminal Archaic periods. I created a geo-database using ArcGIS 10.1 to both help improve data management and to see what additional analyses, like density and orientation patterning, could be used to provide more information about the site. Additionally, GIS was also used to locate other possible Late to Terminal Archaic sites in Connecticut. A cost path analysis was performed between the WRNC-1 site and other known sites of the same period to help identify likely travel routes.

Bragdon, Kathleen (William and Mary)  
[338] Our Strange Garments: Trade Coats and Diplomacy in Seventeenth Century New England  
This paper considers a venerable topic in the ethnohistory of contact- trade coats and other non-native items of clothing, and trade cloth, as they are documented in inventories, native language documents and contemporary descriptions, and represented archaeologically in 17th-century southern New England. Unlike earlier treatments of this subject that focus primarily on the function of imported clothing and cloth, I will consider the political and sacred dimensions of imported clothing, with special emphasis on the role played by gifts of clothing in relations among native elites and English colonial officials in the seventeenth
century. A careful look at patterns of use of imported garments among native elites demonstrates the multifaceted nature of consumption in the early contact period.

The California Sheephead (Semicossyphus pulcher) Fishery: Past, Present, and Future

Beginning only in the late 1980s, the commercial exploitation of California sheephead (Semicossyphus pulcher) has grown to become a complex, multimillion dollar fishery. The fishery is of particular concern not only due to unsustainable harvest levels, but also to the long-term health and structure of kelp forest ecosystems. Unfortunately, very little data exists on the sizes and abundances of sheephead prior to commercial exploitation, which are critical for evaluating 2001 California Department of Fish and Game regulations. Here, we describe our work to apply archaeological data to help evaluate the long-term health and viability of sheephead fisheries in southern California.

Regnat Populus: The Intersection of Historical Archaeology Research and Public Service in Arkansas

Regnat Populus means “Let the People Rule,” and it is the official motto of the state of Arkansas. Embracing this ethos, the Arkansas Archaeological Survey’s mission statement encourages both research and public service. Dr. Thomas Green, while serving as director of the Survey, was a proponent of archaeologists not only doing research for research’s sake, but of reaching out and making the discipline relevant to the public, both in Arkansas and further afield. This paper examines, through the lens of historical archaeology, topics such as descendant involvement, public service, working with volunteers and other ways that, under Dr. Green’s directorship, the Arkansas Archaeological Survey sought to find the intersection between research and public service. Research at Van Winkle’s Mill, Dooley’s Ferry, and Historic Washington State Park, our statewide initiative to document endangered African-American cemeteries, and many more projects are presented to display the rich diversity of efforts that Dr. Green encouraged and supported.

Lithic Raw Material Acquisition, Ethnicity and Source/Settlement Location: An Ethnoarchaeological Study of Ethiopian Craftspeople

Southwestern Ethiopia is probably the last place on earth where craftspeople from diverse ethnic groups obtain obsidian on a regular basis to produce retouched flaked stone tools. These craft workers acquire obsidian from different sources to produce end scrapers of varying dimensions that are hafted onto wooden handles to scrape domestic animal hides. Using pXRF instruments in the field and lab, we analyzed the elemental composition of over 1200 obsidian end scrapers made by hideworkers from different ethnic groups. The results indicate strong correlations between specific source(s), settlement location and ethnic group. We conclude with a discussion of how our research may better inform archaeologists and social anthropologists about the economics of lithic production and trade, social boundaries, territoriality, land tenure, and the construction of social landscapes.

Historical Settlement Ecology at Singer-Moye: Mississippian Dynamics in the Deep South

Singer-Moye is a large Mississippian mound center in Georgia that contains monumental architecture, demonstrates evidence of social stratification, generates assumptions of agricultural intensification, and is characterized by a dynamic history of occupation. Of note is the site’s seemingly atypical upland location on a small stream near the boundaries of two major watersheds. Chronological and spatial data suggest two distinct periods of occupation, including the initial settlement of the site core between A.D. 1100 and 1300, and the expansion of residential occupation onto adjacent landforms between approximately A.D. 1300 and 1450. We interrogate the occupational history of the site at multiple scales of analysis, situating it within macro-regional interaction networks and the settlement landscape of the Lower Chattahoochee Valley. At the local level, we suggest that the cultural practices of Mississippian inhabitants interacting
with the environmentally diverse interior Coastal Plain through time led to a mutually constitutive relationship reflected in the domesticated landscape. This continuing relationship led to the fluorescence of Singer-Moye as a large community during the fourteenth and fifteenth centuries at a time when contemporaneous groups in other cultural and environmental contexts experienced abandonment, reorganization, or social instability.

[121] Imperial Things: Assembling a New Social Order
This paper attempts to think through some of Latour’s premises regarding the inextricable linkages between humans and nonhumans in the context of the Inca Empire. If we are to take Tawantinsuyu as a new type of social aggregate distinct from what preceded in the LIP, we need to consider what kinds of relations were produced as a result of the creation and association of new kinds of objects and actors. If the Inca were the progenitors of a new social formation, this would theoretically be visible archaeologically in the material traces of new assemblages and associations. To begin this discussion, I focus on assemblies within a sample of Late Horizon mortuary contexts from the provinces.

[292] Regional Limestone Geochemistry Study of Maya Stone Resources in the Three Rivers Region, Belize
The construction of Maya site centers has long been assumed to have been accomplished using local bedrock materials. However, data collected at Maax Na and other Three Rivers Region sites challenges this preconceived notion. ICP-MS was used to analyze limestone samples from bedrock outcrops, quarries, and megaliths identified as possible monuments from three sites. The results show that at Maax Na certain monuments, including multiple stelae, do not chemically match the local bedrock. Two other sites sampled in this study, Chawak But’o’ob and Hun Tun, each equidistant from Maax Na at 7 km, have a nearly identical Mg (and therefore dolomitic) composition to that of Maax Na. In contrast, the imported monument stone from Maax Na contains < 0.5% Mg, classifying it as a pure limestone. Given the similar
chemistry at all three sites, these data suggest that the source of this other stone may be some distance away. Since this initial study, three additional sites were sampled and are now being analyzed, expanding the project to a greater regional extent. The results of this research highlight a potential regional trade in monument stone that is as yet undocumented for the Maya area.

[158] Future Directions for Studying Past Climate in the Maya Region
Stable oxygen isotope records and geochemical data from lake sediment cores provide insights into past climate in the Maya Lowlands. A new method that can distinguish between temperature and rainfall effects on oxygen isotope values in lake cores, indicates that late Holocene shifts in $\delta^{18}O$ were driven solely by changes in the ratio of evaporation to rainfall. Data from Lake Chichancanab show protracted dry events at -770-870 A.D. and -920-1100 A.D., with the intervening time period being relatively moister. These climate inferences are supported by new, well-dated, high-resolution isotope evidence for droughts from cave speleothems (stalagmites). Paleoclimate data from local "natural archives" were first generated < 20 years ago and have led to a debate about the role that climate change played in Maya cultural development. The debate is confounded by other factors that influenced culture, including growing Maya populations and their impacts on the lowland tropical landscape, interactions among Maya polities, and social influences from beyond the region. New directions in Maya paleoclimatology should:
(1) explore possible new archives of paleoenvironmental information; (2) quantify the amount and duration of droughts; (3) describe the geographic extent of droughts; and (4) investigate archaeological evidence for responses to climate shifts.

Breslawski, Ryan (Utah State University) and David Byers (Utah State University)
[206] Bison Processing at Baker Cave III (10BN153), Snake River Plain, Idaho
This poster presents an analysis of the Baker Cave III (10BN153) bison materials. Baker Cave III consists of a lava tube containing a late Holocene bison processing site. Our analysis of the Baker Cave archaeofauna has identified at least 37 adult and 8 fetal bison, as well as numerous lagomorphs. Butchering marks indicate that carcasses were generally disarticulated by smashing proximal limb joints. Cut marks indicate a regular pattern of skinning, and impact scars occur along long bone diaphyses, ribs, and mandibles. Models of bone density and economic utility suggest that within-bone fat content is primarily responsible for element frequencies at Baker Cave. This finding is consistent with observations that foragers sometimes target fatty resources in periods of mid-winter scarcity.

Breternitz, Cory
[18] Summary of the NGWSP Cultural Resources Inventory
The Class III cultural resources inventory for the Navajo-Gallup Water Supply Project (NGWSP) was completed in 2013. The inventory included more than 170 miles of a 400-foot-wide corridor across the eastern and western San Juan Basin in northwest New Mexico. The San Juan leg of the project extends from the San Juan River west of Farmington to Gallup and parallels U.S. Highway 491 along the Chuska Slope with branches to Window Rock and Crownpoint. The Cutter leg of the project extends from Cutter reservoir southeast of Bloomfield to Huerfano and crosses both Largo and Blanco Canyons. These two transects across the San Juan Basin recorded hundreds of cultural resources with components that include late Archaic, Basketmaker, Anasazi, protohistoric and historic Navajo, and modern in-use sites. Ethnographic studies and interviews with Navajo residents added to our understanding of historic land use and geomorphology studies contributed to a predictive model of potential buried site locations. Results of the survey are presented in the contexts of the cultural and natural landscape approach guiding the NGWSP research design as they relate to land use, community development, and agricultural potential of the San Juan Basin over the past 5,000 years.

Brewer, Olivia and Dr. David Hill (Anthropology and Sociology at Metropolitan State University)
[46] Petrographic Evidence for the Dispersed Production of Abiquiu Black-on-gray Pottery in North-Central New Mexico
Biscuit wares represent the predominant decorated type of ceramic during the Pueblo IV period across north-central New Mexico. Recent petrographic analysis has identified two compositional groups of
Abiquiu B/g pottery from sites located on the Pajarito Plateau and the Chama and Rio Grande valleys. One composition group was distinguished by a light-colored ceramic paste that contained fragments of glassy pumice and volcanic tuff. Commonly included are fragments of minerals derived from plutonic rock. The plutonic rock fragments and associated minerals in the decorated ceramics are from the presence of xenoliths of Precambrian rocks that have been documented in the Otowi and Tshirege Members of the Bandelier Tuff. This composition group represents vessels made on the Pajarito Plateau. A second composition group has a dark brown paste that contains shards of glassy pumice but lacks the fragments of volcanic rock. This composition group represents Abiquiu B/g vessels that were made possibly in the Chama or northern Rio Grande Valley. The two paste compositions have been observed in sherds of Abiquiu B/g sherds recovered from archaeological site both on and off the Pajarito Plateau and as far north as a small sample from a rockshelter near the Colorado/New Mexico border.

[52] Mapping Medicinal Trail: Hydraulic Modeling at an Ancient Maya Hinterland Community

The Medicinal Trail site, encompassing an area approximately 1 kilometer in diameter, is a dispersed hinterland community located near the major ancient Maya site of La Milpa in northwestern Belize. Occupied primarily during the Classic Period (A.D. 250-900), this terraced community consists of multiple landscape modifications including terraces, depressions, and linear features. Hypothetically functioning as a decentralized water management system, these plaster-paved surface features served to direct water into the natural depressions—or reservoirs—which served as open catchment basins designed in part to collect wet season rainfall and hold sporadic surface runoff or water from more permanent canalized surfaces.

Three seasons of total station mapping have revealed distinct patterns of settlement selection and water management practices. Survey and mapping have revealed a visible spatial relationship between reservoirs and residential areas and archaeological investigation has shown that these depressions served multiple domestic functions over time. Ongoing hydraulic mapping of the site, based on contour mapping and catchment area analysis, will help us to interpret the hydrological landscape of the site through water diversion and conservation measures and accretional landscape modifications, as well as permit us greater insight into the complex interrelationship between water and people within this peripheral settlement.

[29] Climate Change, Resilience, and the Shifting Patterns of Ecological Stress in Iceland's Landscapes

In the pre-modern North Atlantic islands, climate change is likely to have decreased food security because of its direct effects on domestic animal mortality and the availability of grazing. Shortfalls in domestic-animal food production could potentially be buffered through either increased exploitation of wild (particularly marine) resources or the importation of alternate foodstuffs. New archaeofaunal data from the late-13th/early-14th century period at the site of Hofstaðir, in the Lake Mývatn district of northern Iceland, indicate a set of responses (including a significant use of marine mammals) consistent with dietary stress. Though the effects of climate change are not uniformly expressed across landscapes, the spatial patterning of impacts is predictable and can therefore be assessed with numerical modeling. In this paper, we identify these patterns of increased vulnerability through the use of models that simulate shifting patterns of climate stress across the landscape, focusing in particular on northern Iceland. We then test whether or not late 13th-century climate change is likely to have had a significant impact on food security at Hofstaðir. Finally, we discuss the potential further applications of such analyses in the study of social-ecological system responses to climate change.

[150] Emplacing Recuay Authority: The Local Roots of Regional Elites in the Highland Andean Early
Neo-evolutionary frameworks have long structured archaeological accounts of social transformation and political change. In the Andes, scholars uncritically apply such frameworks in describing “horizons” as epochs of civilizational achievement and “intermediate periods” as eras during which people passively responded to broader political economic changes or periods lacking in sociopolitical innovation. This paper challenges these frameworks by presenting recent excavation data from Hualcayán, a ceremonial center and town in highland Ancash that was rebuilt during the Huarás Phase (200 B.C.E.–200 C.E.) as aspiring elites drastically transformed the Chavín-affiliated temple mounds of Hualcayán. These local actors declared their local authority in theatrical practices such as expedient feasts and termination rituals that decommissioned Chavín religious spaces and symbols. The feasting practices of the Huarás Phase became the basis of a regional elite authority during the Recuay Period (200–700 C.E.), when lineage leaders forged formal and recognizable elite identities, casting themselves as providers for the local community by hosting ceremonies in exclusive ritual spaces. Far from an unenlightened moment of political disintegration, Recuay communities flourished through the creative redefinition of established spaces and boundaries, and in doing so, forged new forms of political authority and lineage-based social organization.

The Keladi-Ikkeri Nayakas (1499-1763 A.D.) were established as regional leaders under the Vijayanagara Empire and later ruled as an independent state based in modern Shimoga District, Karnataka, India. Most of what is known about Keladi-Ikkeri Nayaka history is based on an epigraphic record of stone, copper plate, and temple donation inscriptions; this is supplemented by architectural studies of period temples and by a recent archaeological survey of the first two of three Keladi-Ikkeri capitals. This paper reviews these material and textual sources and examines how they can be integrated to explore changing strategies of regional governance by the Keladi-Ikkeri Nayakas. The epigraphic record is then reconsidered as a material rather than simply textual historical source. Inscriptions of modern Karnataka State were first recorded and published during the Colonial Period, and this legacy of antiquated methodology, and colonial political divisions and agendas still plagues modern interpretation of the historical record. I argue that epigraphs should be rematerialized as spatially anchored and physically embodied objects and that archaeological method and theory contribute to accomplishing this task. The Keladi-Ikkeri Nayaka epigraphic record is analyzed as a case study of integrating these data with results from archaeological survey.

Briggs, Rachel (University of Alabama)

Nixtamalization is a method of alkaline processing used to enhance the nutritional quality of maize by first soaking the food in an alkaline solution and then boiling it. Though a common practice in Mesoamerica as well as the American Southwest, this cooking method has not been thoroughly documented in the Southeastern United States, where, it was believed, the common bean was used to nutritionally enhance a maize-based diet and prevent pellagra, a degenerative disease that results from malnutrition. However, studies have shown that Phaseolus vulgaris (the common bean) was rare in the greater Eastern Woodlands before 1300 AD, centuries after the initial appearance of maize in the area (between 800 A.D. and 1100 A.D.). Instead, based on ethnohistoric and ethnographic sources, it seems more likely that prehistoric groups in the area were nixtamalizing their maize using wood ash. This poster reviews the
Evidence for the diffusion of nixtamalization into the Southeast from the American Southwest during the late prehistoric period and explores the relationship between maize, alkaline cooking, and the standard Mississippian jar, the latter a vessel that may be a specific adaptation developed to address an increased need for boiled food.

Briggs, Clive [343] see Gilmore, Kevin

Brighton, Stephen (University of Maryland)  

The study of diasporic groups in anthropology is moving in a new direction striving to reposition and rethink the meaning and use of the term. In this context the importance rests with working on larger scales of reference illuminating patterns or commonalities amongst diasporic groups. In archaeology the term is not employed critically however, but is simply viewed as epiphenomenal. This somewhat a-theoretical structure downplays its role in the discourse of power relations when studying conflict and negotiation of social identity, injustices and racialization, as well as gender and class bias. This paper represents a larger research program seeking to bring historical and material data from diverse diasporic groups such as African, Irish, and Chinese, to critically evaluate similar patterns of social, political, and economic relations and experiences. The use of theory from contemporary anthropology can provide the necessary framework to move past traditional concepts of assimilation and resistance and towards a dynamic discourse uncovering the materialization of experienced racialization and levels of alienation, incorporation, and transnationalism.

Bringelson, Dawn  
[172] The Conundrum of the West Unit: Understanding Dune Land Prehistory along Southern Lake Michigan

Indiana Dunes National Lakeshore contains some 15,000 acres of the last remaining intact dune lands within the highly modified landscape between Chicago, Illinois, and Michigan City, Indiana. Artifacts from the Lakeshore suggest connections between Lake Michigan’s southern tip and cultures across the Midwest, but the nature of these connections remains unclear. This is partly due to difficulties in relating dune archaeology to that found in other settings. Apparent inconsistencies in precontact land use across the Lakeshore provide a chance to look more closely at dune archaeology. Park-wide inventories over recent decades indicate differences in the distribution and density of materials between the Lakeshore’s East and West Units. Intact dunes in the Lakeshore’s West Unit, between Gary and the Port of Indiana, contain a surprisingly sparse record in comparison to that found in the East Unit (stretching from the Port toward Michigan City). Current research examines explanations for this discrepancy, including relative landform age, sedimentary processes within dune formations, and middle to late Holocene human land use.

Britton, Emma  
[144] Results of Petrographic Analysis of Polychrome Ceramics from Site 204, Chihuahua, Mexico

Multiple studies have suggested that specific Chihuahuan polychrome types may be more common in some geographic contexts than others (see Brand 1935; De Atley 1980; Findlow and De Atley 1982; Kelley et al. 1999; Larkin et al. 2004 for more complete discussions). However, these studies are often criticized as they assume that polychromes recovered at sites are made locally, as opposed to being traded (Douglas 1995; Minnis 1984, 1989). In response, some studies have re-focused on the production of polychromes (see Carpenter 2002, Sphren 2003, Woosley and Oliger’s 1993, among others). However, these studies have generally resulted in contradictory interpretations, partly as a result from the lack of complementary data sets and techniques. In my presentation, I will discuss the results of petrographic analysis of polychrome sherds recovered from Site 204, also known as the Tinaja site. These sherds were recovered from a midden context, which is unusual in the Casas Grandes world, and will help describe ceramic diversity at a single site, through time. Preliminary analysis (Britton 2012) suggests that this assemblage demonstrates high diversity. This analysis is the beginning of a regionally comprehensive study that utilizes the same material science techniques to describe Casas Grandes polychromes through space.

Production and Consumption: Theory, Methodology, and Lithic Analysis
During recent decades, archaeological research has focused on the dynamics of production in past societies from multiple theoretical and methodological perspectives; in contrast, the study of consumption remains relatively unexplored, with some exceptions. Processes and practices of consumption in human societies encompass both economic and symbolic aspects, and they play significant roles in historical and cultural change. Moreover, archaeological models of the organization of production cannot be isolate production from practices of consumption. In this paper, we discuss the relationship between production and consumption, offering a methodological framework to analyze lithic assemblages.

Geoarchaeological and geophysical techniques have long been used successfully in archaeological research. However, rarely are the two explicitly integrated into a Cultural Resource Management survey program. This paper focuses on the benefits of multidisciplinary investigations using these combined techniques at two distinct sites in the southeastern United States. One site represents a natural depositional environment and the other an anthropogenically modified landscape. These cases illustrate the effectiveness of the two techniques to provide data on site formation processes, subsurface stratigraphy, and associated features in an efficient and cost effective manner. In addition, this combined approach is minimally invasive, allows for large contiguous areas to be surveyed in a shorter amount of time, and provides subsurface data at logistically complex sites. Most importantly, these multidisciplinary studies provide independent results that strengthen archaeological interpretations. The combined use of geoarchaeology and near-surface geophysics supplies archaeological researchers and cultural resource managers with a reliable cost-effective survey solution that can either be implemented as an alternative to standard investigative techniques or included as part of a larger survey program to aid in defining areas of high potential prior to conventional survey methods.

SHA Social: Developing a 21st century Social Media Strategy for the Society for Historical Archaeology
In 2010, the Society for Historical Archaeology began developing a social media strategy called SHA Social. It was designed as a tool for using social media in order to engage current and future members in the activities of the organization. This paper will discuss the design and implementation of the strategy, and the way that the SHA has used tools like a blog, Twitter, Facebook, and LinkedIn to engage with members and advance the mission of the organization. It will examine some of the success, pitfalls, and obstacles that emerged in the process of establishing SHA Social, and discuss the benefit of using these tools to engage with membership, attract new members, and advance the mission of professional archaeological organizations.

Early Levallois Technology and Its Implications: New Data from Olorgesailie, Kenya
The Olorgesailie basin, in the Rift Valley of southern Kenya, is well-known for its spectacular concentrations of Acheulean handaxes and large game butchery sites, dating from over 1 Ma to 493 ka, as well as for pioneering studies in landscape archaeology. New excavations since 2001 have revealed that these early occupations were followed by a long sequence of Middle Stone Age occupations without handaxes, beginning well before 315 ka and ending before 64 ka. In this presentation, we compare cores from the later Acheulean horizons of Members 11 and 13 of the Olorgesailie formation (between 625 and 550 ka), to those of MSA sites dating from over 315 ka to after 220 ka. We demonstrate that Levallois technology begins to emerge early on in this sequence during the Acheulean, well before its appearance in dated Middle Eastern or European contexts, and we consider the implications of this for human evolution. We also show that Levallois cores are made in many different raw materials, both local and transported, and that their frequency is episodic and non-linear through time. From 220 ka on, however, most sites are characterized by industries with small standardized Levallois cores.

Brooks, Jason (Louisiana State University)

[232] A Plantation Landscape: A Preliminary Discussion of the Differences in Spatial Organization between Sugar and Cotton Plantations

In a time period when cotton was still 'king', plantations in south Louisiana were primarily growing sugarcane. In addition, many of these plantations were also processing the cane within their own plantation complexes. As such, sugar plantations could be seen as being more industrial than their cotton growing counterparts. As part of my dissertation project, this research seeks to determine if any differences exist in terms of spatial organization between the built landscapes of cotton and sugar plantations. Although the overall project will focus on the broader plantation landscape, this poster focuses primarily on the quarters areas of these plantations. As there may be differences in power relations between owners and laborers of these two plantations types, based on the more industrialized nature of sugar production versus the more traditional agricultural nature of cotton, I expect differences in spatial organization exist between the two.

Brosman, Christopher (National Park Service) and Chris Finley (National Park Service)

The Bad Pass Trail located in Bighorn Canyon National Recreation Area has served as a travel corridor in the Northwestern Plains since the Late Archaic Period. Recent investigations conducted due to the replacement of a transmission line through the park have revealed the location of over 30 tipi and travois pole fragments in an exposed surface context. These poles are likely of Protohistoric Crow origin, and show a remarkable level of preservation. In this paper we will discuss the distribution of the poles and their relationship to the visible portions of the Bad Pass Trail. We will also talk about the analysis of the individual poles based on deterioration and function. The topography of this portion of the Bad Pass Trail proved detrimental to many poles and the travois systems used to carry them. Radiocarbon dating and the presence of a dog travois pole point to a critical time in plains groups’ history that may provide more insight into the adoption of the horse into Crow culture.

Broughton, Whitney (University of Mississippi)

[306] Childhood Growth in an Oneota Community: Relating Social Stress to Biological Stress at Norris Farms 36

Oneota migration into the Central Illinois River Valley around A.D. 1300 has traditionally been interpreted as resulting in violent interactions between Oneota and resident Mississippian groups. Some researchers suggest that the threat of violence caused these Oneota communities to limit their subsistence activities to circumscribed areas close to their settlements, thereby reducing their resource base. The nutritional impact of this hypothesized circumscription would have resulted in biological markers that can be seen in the skeletal population at Norris Farms 36. This paper will take a new approach to the effects of violence on this Oneota group by exploring growth patterns amongst the most susceptible members of the group, the sub-adults; in doing so, this paper will lend to a better understanding of the biosocial relationship between violence and physiological growth at the site.

[17] Examining the Archaeology-Soil Erosion Paradox

Geoarchaeology lies at the heart of archaeological debates about societal stability and change. Geomorphological research has been used as a foundation for simplistic models of resource depletion based almost entirely on the comparison of soil erosion rates with long-term so-called “geological” rates. However, the neo-catastrophic collapse of complex agricultural societies is rare, and where it is convincingly demonstrated it is even more rarely monocausal. Indeed many societies appear to have continued agricultural exploitation of climatically marginal lands for far longer than soil depletion estimates would forecast. One reason may be that this soil depletion approach has grossly simplified soil creation through weathering, and neglected how past agriculture also affected the soil creation rate (especially on some lithologies) and how soil was conserved (terraces) and utilized even after transport. However, we now have some potentially valuable new tools, including mineral magnetics and cosmogenic nuclides, which can be used to estimate changing soil weathering rates. This approach will be discussed with examples from both the temperate and Mediterranean climatic zones and in relation to causative models of change in complex agricultural societies.

Brown, M. Kathryn (The University of Texas at San Antonio)

[31] Preclassic Investigations at Xunantunich, Belize

The Mopan Valley Preclassic Project has been investigating a Preclassic center at Xunantunich, Belize, since 2008. This location has large monumental architecture dating from the Middle Preclassic, including an E-Group architectural complex, large flat-topped platforms, and a ballcourt. New LiDAR data have added significantly to our understanding of the site’s formal arrangement. It appears that this location was the original site core of Xunantunich and was abandoned sometime before the Early Classic period. Our efforts to date have concentrated on the E-Group and the associated buried features in the plaza. Excavations in the plaza in front of the central eastern pyramid revealed a large platform with unusual ramp features. The placement of this platform restricts direct access to the central staircase of the eastern pyramid while the ramps allowed access from the side. The complex architectural arrangement of the Xunantunich E-Group suggests an intentionally constructed landscape that functioned as an elaborate stage for ritual activities and processions. Although this location was abandoned at the end of the Late Preclassic, it continued to be an important place for rituals through the Postclassic.

Brown, Gary (National Park Service)

[56] Beyond Chaco: Testing the Boundaries of the Middle San Juan Region at Aztec

Do Chacoan outliers provide evidence of migration from Chaco Canyon into surrounding areas? Research in the Middle San Juan region supports this assumption at some outliers, while indicating that emulation of Chacoan greatness is more likely at others. Architectural analysis supports the view that Aztec and Salmon were colonized by Chacoan migrants between A.D. 1090 and 1115. Emulation preceding colonization suggests that experts in the design, planning, and construction of Chacoan buildings would have been welcome, particularly at Aztec where the northern great house was built in vernacular fabric prior to construction of the western great house where collaboration between locals and Chacoan migrants produced an architectural hybrid.

Brown, Terry (University of Manchester)

Archaeological remains sometimes contain ancient DNA (aDNA) from bacteria and other disease-causing pathogens. Most work has been done with tuberculosis (TB) as Mycobacterium tuberculosis infection sometimes results in changes to the bone structure that can be recognized when archaeological skeletons are examined. We typed 228 variable sequences in M. tuberculosis aDNA from the skeleton of an adolescent female who died in Leeds, UK, late in the 19th century. The genotype was similar to a strain of M. tuberculosis that is relatively uncommon today but is known to have been present in North America at that time. We have also obtained less complete genotypes for nine other M. tuberculosis strains from the 2nd–19th centuries, showing strain variations over time that fit the evolutionary scheme for M. tuberculosis predicted by genome sequencing of extant strains. DNA extracted from archaeological
bones also contains sequences derived from gut and respiratory tract microflora, including pathogens that cause disease in their own right or as co-infections with TB.

[153] Recent Investigations in the Department of Chinandega, Nicaragua
Since 2009, we have been exploring the previously-unstudied Department of Chinandega, in northwest Nicaragua, to investigate migration, ethnicity, and border processes. In 2013, we spent 6 weeks in the field conducting site survey and evaluation. To date, we have located 33 sites, conducted test excavations at 6 of them, shovel tested 2 others, and made surface collections at 10 others. Most of the sites are prehistoric. Some contain architectural remains, mounds or foundations or both. Some appear to be salt-making sites. One may be a chert quarry. Two sites contain significant historic occupations with contemporaneous architectural remains. Our ceramic studies demonstrate that the department of Chinandega does not participate in the ceramic sphere associated with the Gran Nicoya subregion but rather is closely linked to neighboring areas of eastern Honduras and El Salvador. Our lithic analyses document a wide range of raw materials and industries. We have also carried out paleoethnobotanical and geoarchaeological studies. Despite our extensive efforts, we still have much to do. Large areas, such as the Peninsula of Cosegúina, need further exploration, and the cultural sequence remains embryonic. Site destruction caused by mechanized agriculture and aquaculture appears to be unusually severe in the region.

[163] Archaeological Evidence for Asphaltum Production on San Nicolas Island, CA: Acquisition, Processing and Application at the Tule Creek Village Site
Asphaltum (bitumen) is a petroleum product that was used extensively as an adhesive and water proofing agent for thousands of years in California. Fragments, cakes, and other asphaltum encrusted artifacts preserve well in the archaeological record, allowing for a thorough analysis of the asphaltum production process. This study uses a multidisciplinary methodology to trace the sequence of events in which asphaltum was acquired, processed, and applied at a Late Holocene site on San Nicolas Island. Spatial distributions are used to interpret activity areas within the village space. These data show that villagers acquired asphaltum from the island’s shore and utilized the substance for a variety of applications that supported village autonomy.

[237] Plant of a Thousand Uses: Agave in Culture
Found in early cave deposits, Agave has long been exploited by cultures of Greater Mesoamerican and the American Southwest. Used not only for food and drink, it was also an important source of fiber for cordage and clothing. The widespread use of agave cordage may have garnered it a position within the ritual universe long before the development of agriculture. Suspected to be one of the first plants domesticated by hunter-gatherers, it was farmed on a large scale by the Hohokam in late first millennium AD southern Arizona where agave ovens near ballcourts and mounds indicate its continued use in ritual. By the postclassic, the spread of pulque consumption across central Mexico brought a series of
associated local deities led by the goddess Mayahuel. Despite its multivalent presence in the cultures of the region, agave has never been accorded the respect of better known cultigens. In this paper, we present selected highlights of agave-human interactions over the past few millennia and offer suggestions for a reassessment of its historical significance.

Brown, James (Northwestern University) and John Kelly (Washington University) [251]  
Canonical Meanings and Ritual at Cahokia
This paper addresses the ways in which ritual contexts at Cahokia have been identified by generations of archaeologists. Differing expectations about how ritual is materialized have impacted observations of ritual manifestations at Cahokia, and with it the communicative aspect of visual symbols during the period between A.D. 1000 and 1400. We argue that canonical meanings are generated by ritual that, in Norbert Elias’ terms, creates social figurations among ritual actors. As the number and complexity of these figurations grow, visual symbols will take on canonical meaning that will spread communication throughout the subcontinental web of these figurations.

Ancient DNA Analysis of Paleoeskimo and Thule Dog Remains from the North American Arctic
The peopling of the High North American Arctic, occurred in two waves. First the Paleoeskimo people migrated from Siberia roughly 4000 B.P., followed by the Thule people ca. 1000 B.P. The Thule people are known for their innovation and rapid colonization of the North American Arctic, compared to small population sizes of the Paleoeskimo. A distinguishing characteristic of Thule culture relative to previous Arctic cultures was increased use of dogs, particularly for dogsled traction. Use of dogs by the Thule is reflected in the archaeological record by a dramatic increase in dog remains in zooarchaeological assemblages. Here, we present results from an Arctic wide survey of over 450 ancient dog samples and analysis of the temporal and spatial distribution of dog remains and their genetic characteristics. We compare diversity of the D-loop region of the mitochondrial DNA in Thule and Paleoeskimo dogs from Siberia, Alaska (Interior as well as Coastal), Canada, Greenland to assess origins, interchange, and changes through time. We show that, similar to their human companions, domestic dogs colonized the North American Arctic in two waves.

Brown Vega, Margaret (IPFW), Nathan Craig and Gerbert Asencios Lindo [146]  
Awqa Pacha: Fortified Landscapes of the Pativilca Valley, Central Coast of Perú
This paper presents data from newly documented fortified features in the Pativilca Valley, on the central coast of Peru. Using spatial data collected from the mapping of architecture and surface assemblages, the relationships between defensive architecture, fortified attributes, and landscape features are explored. Pottery and lithic types, as well as special artifacts, yield insight into the temporal assignment of sites, many of which are multicomponent. The earliest fortifications in the valley date to the Early Horizon (ca. 900-200 B.C.), or the transition to the Early Intermediate Period (ca. 200 B.C. – A.D. 200). Extensive fortified complexes characterize the Middle Horizon (ca. A.D. 500-1000). There is little indication that forts were heavily used in subsequent time periods. These data are considered along with regional data on fortifications from neighboring valleys. Analysis of the overall distribution of forts both temporally and chronologically indicates a distinct pattern of fortification for the Pativilca Valley. Results add to a growing database of fort locations and attributes for the coastal region of Peru, and lend further support to the need to consider conflict or defensive measures in local historical sequences.

Browne Ribeiro, Anna (The Ohio State University) [149]  
Every Little Bit Helps: Micro-Analyses as a Vector for Understanding Causation in Social-Ecological Shifts
Terra preta, a type of Anthropogenic Dark Earth found throughout the Amazon, has become an important piece of evidence in exploring forms of habitation in pre-Columbian Amazonia. Seen as evidence of densely-settled permanent towns, terra preta is one among many indices of anthropogenic environmental engineering in what was previously thought to be a pristine forest. Contemporary literature on Amazonia has more than confirmed a correlation between intensification in terra preta production and settlement growth, increased investment in terraforming, and refinement of technical industries. As a step toward understanding the nature of this transition, conceptualized in this paper as a regime shift, I propose that
every ecological shift has a primary or principal causal vector. For terra preta, the principal manner that human influence is transmitted to the soil is through momentary or microscopic encounters, such as individual acts of deposition or sealing of contexts through construction. The sum of such miniscule encounters of social and ecological systems is what eventually leads to regime shift.

Bruhns, Karen (Fundacion Nacional de Arqueologia de El Salvador)
[281]  *Heads in the Sand, Feathers in the Air: Undocumented Antiquities and American Archaeology*

Artifacts purporting to be Precolumbian have been common in South America since at least the 1880s, a fact which has been just as continuously ignored by art historians and most archaeologists. With the enormous boom in the collecting market beginning in the 1960s forgery has become a major industry, filling the galleries, private collections and museums of the world, including many in South America, with art works of highly dubious authenticity. This, in its turn, has severely impacted reconstructions of ancient cultures and their ideological systems and threatens to make ludicrous many more interpretative schemes. It is more than time for the mantra of authenticity for undocumented artifacts to change from real until proven fake to fake until proven genuine.

[79]  *Archaeological Investigations of the Platt Historic District at Chickasaw National Recreation Area: Results of 2013-2014 Field Work*

The Platt Historic District in Chickasaw National Recreation Area (Murray County, Oklahoma) presents a landscape of natural mineral and fresh-water springs which create an inviting place for people to settle, develop, and enjoy. From pre-contact use, to resort town, rustic National Park, and further development by the CCC, the area has experienced a number of iterations. The many facets of the historic town will be explored as one aspect of a joint project between the University of Nebraska-Lincoln, the Midwest Archaeological Center, and Chickasaw National Recreation Area. This poster will highlight the research design for the archival research and historic map analysis that was used to discover locations of features and structures that span the human utilization of the park and preliminary results of field work conducted in 2013-2014.

[105]  *The Materiality of Death: Functional Materialism and the Kusikancha Burials*

In the ancient and modern world, the dead from elite groups are interred with finely crafted objects made from precious materials in their tombs. Often for the elite, many high quality and precious objects have been preserved, making it possible for archaeologists investigating the ancient world to partially reconstruct these ceremonies and begin to understand these cultures’ view of death. Using Dr. Kathlyn Cooney’s idea of functional materialism, I will probe the relationship between the eternal body of the deceased and the objects they were buried with and analyze the types of burial objects used in the rituals and placed in the tombs. For this project, I am studying the dataset from the burials at the Kusikancha, a ritual site that contained 22 Inca elite mummies in the Inca capitol. During this period, the Inca polity was a regional state with a large area of influence, focused materially, interested in the preservation of the body in the afterlife, and supported a stable elite. By using the idea of functional materialism, we can arrive at a clearer understanding of how regional states institutionalize the funerary process and celebrate
their elite in death as they did in life.

Bryant, Vaughn (Texas A & M University)

[283] Forensic Archaeology & Pollen: Why Use It
Sampling for pollen at forensic archaeological sites should become a standard procedure. Not all samples need to be examined, but samples should be stored correctly to prevent post-collection contamination and to retain their value as trace evidence. Once the crime scene is disturbed during recovery, the opportunity to obtain later samples is impossible. Pollen recovered from burials and other features associated with the recovery of materials related to criminal or illegal civil activities can sometimes be of great value in helping to understand the recovery site and its contents. Pollen might be able to assign a geolocation to the person or material that is recovered from a site. Secondary burials resulting from the removal of items from one location, which are then reburied at a new location, can often be detected through examining the included pollen. Determining the origin of the fill materials at a burial or feature could be enhanced through the recovery of included pollen. Associating pollen from a crime scene with clothing or an item owned by a suspect could provide essential evidence. Finally, in some cases the season of burial or season of usage might be revealed from the included pollen in the feature.

Bryant, Jeff

[341] Soil is Social: Investigating Maya Soil Dynamics and Social Stratification during Climate Change with X-Ray Fluorescence Spectrometry (XRF).
This paper will investigate both social stratification and agricultural potential in the Petén Maya lowlands using both traditional measures of available soil nutrients and total elemental concentration as reported by X-Ray Fluorescence Spectrometry (XRF). A comparison of the data will demonstrate the need for building an understanding of the local nutrient cycle dynamics when interpreting soil data. The capacity of the soil to make nutrients available has major implications for how much of a chemical will be detected, and how we use our data in answering questions about the environment and society. This study will investigate a local problem in the phosphorus nutrient cycle and test if elite sites are more fertile than commoner sites for anthropogenic reasons. Potential uses for XRF in soils archaeology will also be discussed such as detecting and measuring processes of erosion and intensive cultivation over time.

[141] From Here and There: Flaked Stone from the Obsidian Cache Pithouse Site of Southwest Utah
The excavation of site 42Ws4474 in 2006 by HRA, Inc. recovered a notable flaked stone assemblage. In particular, a burnt pithouse dating from cal A.D. 60 to 240 (Beta-Analytic sample 240766), contained two caches of obsidian flakes, scattered debitage, five bifaces, and nine projectile points. The flaked stone assemblage was analyzed in co-operation with the Northern Arizona University Anthropology Department. The analysis concluded that multiple, locally available material types, as well as obsidian sourced to two locations to the northwest, were used in a variety of tasks. In general, cobbles of suitable material underwent unpatterned core reduction for flake production. Flakes were then used as tools, as well as for blanks, to create bifacial tools. The corner- and side-notched projectile points show similarity with other Basketmaker II assemblages. Quantitative and stylistic comparisons with Basketmaker II collections from Cedar Mesa, the Rainbow Plateau, and the Durango area (Bryce 2010) show the greatest similarity with bifacial tools from the Rainbow Plateau collection.

[8] The Construction and Use of Public Space at Cerro de la Virgen, Oaxaca, Mexico
This paper presents the results of recent archaeological investigations at the site of Cerro de la Virgen, a secondary political center located in the hinterland of the lower Río Verde Valley, Oaxaca, Mexico. Research at Cerro de la Virgen is designed to examine the articulation between outlying sites and political centers, with a focus on how contestation and negotiation at a regional scale influenced political organization. During the Terminal Formative period (150 B.C.–A.D. 250), the lower Verde witnessed the brief fluorescence of a complex polity with its political seat located at the urban center of Río Viejo. Excavations conducted in early 2013 at Cerro de la Virgen examined the construction techniques and use
of public space within the ceremonial core of the site to compare them to similar contexts at Río Viejo and other outlying sites. Preliminary analysis indicates significant differences in the ways people constructed and used public buildings at Cerro de la Virgen compared to other sites in the region. We argue that this variability supports the hypothesis that regional integration at the end of the Formative in the Río Viejo polity was limited, and these public, sacred landscapes were planned and built by local populations.

Buchanan, Meghan (Indiana University)  
[15] Reconfiguring Regional Interactions in the Face of Cahokian Decline: A View from the Common Field Site, MO

Following the Cahokian Big Bang (ca. A.D. 1050), regional interactions in the Midwestern United States were drastically reconfigured as immigrants and pilgrims came to the American Bottom, traders and missionaries interacted with new people, places, and materials, and polities throughout the region rose and vied with each other for power and prestige. Several models and theories have been proposed for explicating the beginnings and political climax of Cahokia. However, the later dissolution of Mississippian polities (especially the Cahokia, East St. Louis, and St. Louis mound centers) and their impacts on regional interactions are less well understood. In this paper, I assess the utility of Green and Costion’s Model of Cross-Cultural Interactions for this period of political turmoil, negotiation, shifting borderlands, and eventual abandonment during the late 12th-14th centuries in the Midwest. In particular, I focus my attention on the Common Field site, a political and religious center located in a region that had been sparsely populated prior to A.D. 1200. I suggest that rather than focusing on former political centers, communities that are established during periods of decline and collapse (like Common Field) hold the keys for understanding novel, shifting, and dissolving interactions.

[89] Using Portable Antiquities to Understand Identity Creation: A Case Study from Viking Age Scotland

This paper explores the portable, non-indigenous material culture strongly related, but not exclusive, to one ethnic group in the medieval period: the Vikings. It is based on the ideas that people from different cultural backgrounds cannot come into contact with each other without having their identities altered in some significant way, and that these altered identities will be expressed in their material culture. During the period from approximately A.D. 800 to 1100, the Vikings initiated contact with inhabitants of Britain, first by raiding and attacking, then by trading and settling amongst the local populations. Whereas most research of Viking and local interaction has focused on Viking settlements in the Northern and Western Isles of Scotland or the Danelaw of England, this paper focuses on peripheral regions where there are increasing amounts of evidence of Viking activities and interactions with the local peoples. Three key research questions are asked of materials found within this region: (1) How and why did items of Viking material culture enter regions outside the centers of traditional Viking settlements? (2) How and why were these items used to conduct meaningful contacts and interactions with local groups? (3) How and why were identities constructed in these regions?

Buchanan, Briggs (University of Tulsa)  
[193] Point Type Diversification: A Quantitative Test of Competing Hypotheses

Understanding the causes of spatial and temporal variation in the number of point types is an important task for archaeologists. In this study we tested two hypotheses regarding drivers of point type richness. One avers that point type richness is dependent on population size such that larger populations will have more types than smaller populations. The other hypothesis argues that the number of point types utilized by a population is governed by environmental risk. We tested these hypotheses with data from Texas. We calculated point type richness by region and time period, and then measured the statistical association between point type richness and proxies for population size and environmental riskiness. Point type richness was uncorrelated with population size in both analyses. In contrast, point type richness was negatively and significantly correlated with one of the risk proxies—average annual precipitation—as predicted by the risk hypothesis. Our results suggest that risk was a more important driver of point type richness than was population size in the area that is now Texas, and therefore add weight to the argument that variation in point type richness should be interpreted as adaptive.

For this NASA-funded project (award NNX13AP66G) we examine whether sub-pixel artifacts (i.e. site middens, obsidian artifacts, and pottery sherds) can be directly detected/identified using airborne and spaceborne image data. Our objectives are to: (1) use NASA image data in conjunction with actual field/laboratory measured spectra of archaeological materials to test the detection limits of the selected artifact classes at the sub-pixel scale by applying previously demonstrated theoretical detection limit modeling; (2) examine the influence that background, seasonal vegetation change and other on-site changes have for the detectability of these objects in image data; (3) establish the instrumentation, spatial scale, and spectral bands needed to improve the detectability of these objects; and (4) to test predictions of new locations for artifacts at specific (spatial) densities in other image scenes and ground truth these predictions. We are investigating locations at Glass Mountain, CA (obsidian) and southern New Mexico (pottery). Visible and TIR are the primary image data used. Spectral characteristics of targets and backgrounds will be measured and a mixture model constructed linking these spectra to image data. Success will be evaluated by mapping predicted concentrations nearby and conducting ground truthing to determine accuracy.

[62] Olmec-Style Sculpture on the Sierra de Santa Marta, Los Tuxtlas, Veracruz: Reflections

Six seasons of archaeological fieldwork in the Sierra de Santa Marta, Los Tuxtlas, Veracruz, have documented several pieces of sculpture executed according to Gulf Olmec stylistic cannons. In combination with previously published pieces, such as the San Martine Pajapan sculpture No.1, this collection displays notable similarities and differences in the expression of Gulf Olmec sculptural traits. In this paper we reflect on possible reasons for these patterns, arguing that synchronic social distance, rather than diachronic distortions, played a major role in this regional stylistic variation.

[111] Changing the Parlor: Household Life-Cycles and Redefining the Home’s Public Space

The Victorian parlor is often held up as a space where late-19th century families exhibited their worldliness and social acumen. These spaces were not static monuments to Victorian values, however, as they served specific, and shifting, purposes for the families who kept them. In this paper, I consider the ways in which the parlor of a prominent late-19th-century San Francisco family, the Hutchinsons, changed as the life-cycle of the family progressed. In the 1870s, the Hutchinson parlor was created as a place for the performance of an elite family class status. In the 1890s, however, the younger generation of the family, including daughter Kate F. Hutchinson, began to tend to the family home more actively. Kate was involved in the Ladies Protection and Relief Society, carrying on the tradition of social activism that her father James S. Hutchinson had set as a founding member of the San Francisco SPCA. When she became the matriarch of the household, parlor furnishings changed, with expensive and ostentatious items hidden away. I argue that home furnishings and other material culture were involved in the generational negotiation of the meaning of the parlor and its relationship to one’s performance of gender and public persona.

[301]  Landscapes of the Dead: Spatial and Typological Analysis of Burials in the Byan-Zherek Valley, Kazakhstan

Burial archaeology has been a primary focus of Central Asian archaeology since before the Soviet era, and continues to be a valuable source of information for bioarchaeological and materials based research today. This project seeks to compare burial construction and distribution in the Byan-Zherek Valley in eastern Kazakhstan against a general typology for Central Asian burials. Preliminary ground survey as well as Google Earth was used to identify and categorize burials chronologically based on structural elements and spatial characteristics. The structural elements focused on are size, form, and, if possible, material of construction. The spatial analysis, conducted through the use of GIS, looks at grouping of burials and patterning with regards to other burials and landscape features. By examining the similarities and deviation of this valley’s burials from the general typology, we hope to comment on the region’s participation in or rejection of cultural processes relating to burial practices. Analyzing burials on multiple temporal and spatial scales will also inform us about the value and weaknesses of typologies for this region and the need for reevaluating what have otherwise been seen as universal attributes.

[67]  Cosmopolitan Populations? Strontium Isotope Analysis from ed-Dur, UAE

A cosmopolitan population involved in an extensive international trade network, demonstrated by the presence of foreign artifacts, would have been made up of individuals of mixed origins. The coastal site of ed-Dur, located in the modern-day Emirate of Umm al-Qaiwain occupied primarily from A.D. 0-250, was a strategic part of an extensive international trade network. Strontium isotope analysis is a useful tool for exploring hypotheses surrounding origins and migration in archaeological populations. By acting as a geochemical marker of a particular region, the ratio of strontium isotopes in teeth can be used to identify an individual's origin.

This study investigates origin in six individuals buried at ed-Dur. Of the six individuals tested, four showed strontium values comparable to the local signature. The other two exhibited signatures indicative of foreign origins but do not appear to have come from the same place. A tooth from a camel interred among the human remains was also tested and showed an analogous signature to one of the foreign individuals. The results indicate multiple origins, congruous with the notion that the population at ed-Dur was cosmopolitan.

[70]  Interpreting a Specialized Cache of Human Remains in Actun Kabul, Central Belize

Excavations by the Central Belize Archaeological Survey in Actun Kabul, a large cave in the Roaring River Valley of central Belize, focused on two discrete features containing high frequencies of ceramics and human remains comprising teeth and phalanges. While commingled burials are found en masse in the terminal chamber, these caches containing very specific elements are located in the middle portion of the cave where no primary or secondary burials occur. We attempt to interpret the nature of these unusual deposits using clues derived from spatial and archaeological data relating to their placement within the cave, a bioarchaeological analysis and inventory of the elements, and analogies with caching practices involving human remains found in ethnographic, ethnohistoric, and epigraphic sources. This study specifically relies on models of analysis for cave contexts championed by James Brady, including the identification of specific rituals, as well as the investigation of how spaces within caves were differentially used by the Maya.

[46] **New Perspectives on Sapawe Flutes and Whistles**

Bone flutes and whistles recovered from archaeological sites of the Chama Valley are recognized widely as markers of the ceremonial elaboration that accompanied the concentration of large populations in ancestral Pueblo settlements and set the Pueblo IV period (A.D. 1275–1600) apart from earlier occupation in the Valley. And yet, we know very little about how these instruments were played and even less about the socio-cultural contexts of whistles and flutes and their relationship to sound generation for musical performance or, even perhaps, avian husbandry. Using perspectives derived from theory in Music Archaeology, faunal analysis, and acoustic modeling, this poster challenges existing conventions that flutes from the site of Sapawe were produced strictly from turkey bone and reconsiders the functional differences in the utilization of flutes with multiple tone holes versus whistles assumed to be bird calls. We further consider the role of Sapawe as a potential center for flute and whistle production, and the performance aspects of playing flutes and whistles alone or in groups that in turn may have influenced not just the dynamics of sound production but also those of supply and demand.

Burger, Richard (Yale University), Lucy Salazar (Yale University) and Jorge Silva (Universidad Nacional Mayor de San Marcos)

[281] **Lost in the Mist of the Ceja de Selva: A U-shaped Formative Complex in Moyobamba?**

This talk considers an anomalous site with impressive stone masonry located near the town of Moyobamba in the Peruvian ceja de selva. The hypothesis that this site corresponds to an Initial Period or Early Horizon U-shaped complex related to Chavín de Huantar and other coeval centers on the coast and in the highlands is evaluated and rejected. Archaeological and historical evidence is presented that the site was probably the result of the Inca efforts to conquer the ceja de selva. If so, it would be one of the easternmost archaeological examples of these imperial efforts in what is now northern Peru.

Burghardt, Laura (University of Arizona)

[79] **The Vernacular Architecture of Homesteads in Cebolla Creek, New Mexico**

Vernacular architecture is an expression of culture, and the study of buildings can reveal much about those who designed and constructed them. This project explores the architecture of several late nineteenth and early twentieth century homestead sites in the Cebolla Creek area of west-central New Mexico. The dwellings in this isolated canyon were constructed very differently, varying in materials, construction method, and architectural style. The individuals who constructed these homesteads came from different locations, had different occupations, family statuses, ethnicities, and life stories. Moving to a new place, homesteaders made decisions about building construction to meet their needs, considering the ecosystem and available resources, but much of the knowledge used in construction and design was cultural. Were some of these factors more influential in the architectural differences among the homesteads? This poster presents the results of combined biographical and architectural research at these sites and interpretation of the reasons behind the architectural differences.

[191] **Descifrando la identidad de un pueblo fronterizo: Investigaciones en el sitio Río Amarillo, Copán**

Located in the eastern section of the Copan Valley, Honduras, lies the Precolumbian settlement of Río Amarillo. Previously, several scholars, on the basis of site maps, proposed that the East Group of the Ceremonial Core was inhabited by a non-Maya population. From 2012-2014 excavations conducted in this area by the Proyecto Arqueológico Río Amarillo-Copán (PARAC) have provided significant information on the identity of the Late Classic period population in this residential zone. While building styles largely employ river-cobble architecture, with occasional cut-stone blocks of toba, the ceramics reflect a participation in the economic sphere of Late Classic Copan as well as some exchange with the interior of Honduras. During at least one period of occupation of the East Group, the inhabitants employed an effigy of K’inich Yax K’uk’ Mo’ in their religious practices, suggesting an affinity with ritual practices of the great city to their west.
Burke, Ariane (Université de Montréal), Dario Guiducci (Universite de Montreal) and James Steele (University College London)  

Seeing our Way: Perception of the Landscape and Patterns of Hominin Dispersal

The scope of hominin dispersals and their chances of long-term success must have depended upon the ability of individuals to plan and navigate their way through the landscape (wayfinding), communicate spatial information to others, follow established routes and recognize landmarks. In this paper we consider how landscape legibility could have affected the ease with which Middle Paleolithic hominins developed cognitive maps, oriented themselves and navigated through the landscape (Lynch 1960). Following Golledge (2003) we consider three aspects of legibility: (1) spatial coherence ("legible" environments have spatial coherence, enabling object clustering and feature characterization as well as hierarchical ordering of phenomena); (2) ease of travel (the facility with which people can move through an environment); and (3) the way in which sociocultural meanings impart legibility (by imparting meaning to certain landmarks even though their physical characteristics would not normally distinguish them from similar, nearby features). The goal of this research is to develop a means of operationalizing these concepts, applying them to archaeological analyses of hominin dispersal patterns during the Late Pleistocene.

Dark Waters and Darker Artifacts: Using PXRF to Analyze Chert Provenance and Patina Formation in the Aucilla River, Northwest Florida

This paper will present the results of an extensive Portable X-ray Fluorescence Spectrometry (PXRF) study analyzing the ability of PXRF to determine chert provenance. A sample of 110 artifacts from the Wayne’s Sink Site (8JE1508/8TA280), a submerged quarry located in the Aucilla River in Northwest Florida, was compared with raw material samples collected from the chert outcrop at Wayne’s Sink. This quarry was only accessible until the Early Archaic period, when it was inundated by rising seas levels. The assemblage analyzed was excavated from deflated and submerged context, and has thus acquired a range of heavy patinas of unknown origin. This research will determine not only the applicability of PXRF to chert provenance studies, but also the geochemical changes and environmental factors that have resulted in the heavy staining of stone artifacts regularly found in the Aucilla River.

Burke, Chrissina (Northern Arizona University) and Gary Haynes (University of Nevada, Reno)

Carnivore Modification of Plains Bison Bonebeds: Explaining Variability Using the Scavenging Ecocenter Concept

Bison bonebed assemblages of the Northern Great Plains exhibit varying degrees of overall carnivore modification. In previous research studies these data have been quantified and used in isolating taphonomic events or patterns influencing site formation processes. This paper presents the Scavenging Ecocenter, a conceptual framework for evaluating the variability in degree of carnivore destruction to large ungulate mass kills. Using several bison kill sites from Colorado and Wyoming, the Scavenging Ecocenter is explained and employed in analysis, allowing archaeologists to draw conclusions from zooarchaeological assemblages that not only represent site formation processes, but are also useful in identifying the human impact that hunting large numbers of bison had on scavenging predators. While the results of this study are preliminary, this research illustrates that more information can be gained from taphonomic patterns than merely explanation of taphonomic processes.

Burks, Jarrod (Ohio Valley Archaeology, Inc.)

Geophysical Survey in Cemeteries: It’s About More Than Just Finding Graves

Cemeteries are perhaps one of the most common places to conduct geophysical surveys in the United States, especially in the context of cultural resource management. And yet, graves are notoriously difficult to detect on a regular basis, being subject to the vagaries of soil types, weather/soil moisture conditions, and grave specifics (e.g., grave size, content, and age). Graves often elude detection even when three or more geophysical instrument types are used. However, there often is more to a cemetery than its graves. Other features, such as roads, fences, plot markers, building foundations, grave-side furniture, and plow marks around the outside of cemetery, to name some of the major ones, can be quite useful for determining the structure of a cemetery. In this presentation I discuss the geophysical signatures of a variety of non-grave cemetery features and show how they might be used to zero in on the location of unmarked graves.
Burnett, Paul (SWCA Environmental Consultants)

Adaptive Management in the Niobrara Oil Play: Probability Modeling for Cultural Resources

Cultural resource management in Northeast Colorado is adapting to the demands brought on by the Niobrara Oil Play such as threat of impact from geophysical exploration and infrastructure development (e.g., well pads, pipelines, and roads). As most of the land is privately held, both public land managers and privately held companies face a challenge of effective management on properties controlled by others. Adding to that challenge are the competing goals of minimizing commercial costs and maximizing public resources values. Probability models developed for various types of archaeological sites in the region help resolve these challenges. Models, as exemplified here, benefit the situation from a purely archaeological perspective by identifying broad patterns in the archaeological record, reaching across private and public lands, while giving managers and companies another tool for use in project planning, reducing uncertainty.

Burns, Jonathan (AXIS Research, Inc.)

Teaching Archaeology in the Trenches: Academic Departments, Non-Profits, and Historic Preservation in Pennsylvania

As state and private anthropology departments compete for student enrollment, those involved with hiring in cultural resource management (CRM) are typically less than satisfied with the training students are receiving in academic programs. Two Field Schools, offered by the Pennsylvania State University and Juniata College, serve as examples of the successful pairing of undergraduate courses in applied anthropology with significant local archaeological projects. The involvement of non-profit organizations helps to further cohesion and integration of the projects by providing stable platforms for networking and mentoring. With this new approach to education, students are empowered because of the training and trust instilled in them through participation in experiential learning, making them qualified candidates for the practical roles that archaeologists serve in the twenty-first century.

Burns, Clareanna

To Quarry or Not to Quarry, That Is the Question

Lake County, Oregon hosts some of the oldest Northern Great Basin cave sites including Fort Rock and the Paisley Caves, as well as numerous lithic scatters and notable rock art sites. Lithic assemblages from this region often contain up to 30% basalt. In August of 2013, the Dismal Spring Basalt Quarry in the South Warner Valley was recorded with the Lakeview District Bureau of Land Management. Being the first recorded prehistoric basalt quarry with the Lakeview District BLM, the Dismal Spring Basalt Quarry poses challenging questions. Why haven’t more basalt quarries been recorded? Is this because we have failed to locate and document basalt quarries thus far? Or is it more attributable to sporadic prehistoric procurement patterns that vary significantly over time and geography? This investigation probes our understanding of prehistoric basalt procurement and use patterns using the Dismal Spring Basalt Quarry as a preliminary model for future basalt quarry research in the Warner Valley and Northern Great Basin archaeology.

Burrillo, Ralph (University of Utah)

Beans, Baskets and Basketmakers: A Test of Cooking Limitations in the Pre-Ceramic Southwest

Paleodietary reconstruction attests to heavy reliance on maize among Basketmaker II groups living in the Colorado Plateau region by at least 400 B.C. Maize is notably deficient in two essential amino acids, lysine and tryptophan, making it a poor protein food on its own. Early Mesoamerican farmers mitigated this shortfall by supplementation with beans, but beans do not appear in the archaeology of the Basketmaker region until around 500 A.D. Researchers have long assumed that the late arrival of beans is contingent upon the need for ceramic cooking vessels, and have advanced numerous hypotheses to account for concomitant nutritional implications. To test this assumption, a series of experiments was designed to examine the feasibility of preparing beans in pitch-lined baskets. Results of these tests offer clues about the subsistence strategies and diet breadth of pre-ceramic Basketmaker populations.

[265] Post-Fire Inventories and Hunter-Gatherer Use Intensity as Exemplified at the Caldwell Creek Site (48FR7091), Fremont County, Wyoming
Interpreting the use of mountainous regions by prehistoric and historic hunter-gatherers has been hampered through the years by difficult access, excessive ground vegetation, and wilderness restrictions. With the advent of forest fires that burn thousands of acres and expose hundreds of archaeological sites every summer, our knowledge of campsite structure and extent has grown rapidly. We now know that remote campsites often contain tens of thousands of artifacts that represent a greater commitment to mountain resources and places than previously considered. New recording methodologies have been employed to properly document these sites. In this paper, we describe recent efforts to inventory the Caldwell Creek site, which was exposed by the Norton Point fire in 2011. In addition to an overwhelming number of lithics, the fire also revealed numerous diagnostic Mountain Shoshone artifacts, including ceramics, side-notched and un-notched projectile points, and a wide variety of Shoshone knives and bifaces.

[221] Archaeological Data Recovery at Mitchelville (38BU2301), a Freedmens Village, Hilton Head Island, SC
Brockington and Associates undertook a Phase III data recovery at Site 38BU2301 at the Hilton Head Island Airport, on Hilton Head Island, Beaufort County, South Carolina. Site 38BU2301 represents a portion of Mitchelville, a village first established by Federal authorities in 1862 during the Civil War as a freedmen’s community. Unlike other contraband camps, Mitchelville developed as an actual town, with neatly arranged streets, quarter-acre lots, elected officials, and compulsory education. Archaeological investigations recovered the remains of individual houses and larger features, including barrel wells, trash middens, and trash pits.

[286] A Drop in the Bucket: Characterizing Complex Middens with 10 Liter Sample Units
Our ongoing project is examining intra-community response to high magnitude earthquakes and other environmental change through analysis of the faunal remains and, by extension, subsistence strategies, from a large coastal village in Washington occupied 1800-100 B.P. The extensive horizontal exposure (> 500 m2) yielded enormous faunal samples, and the remains of multiple houses that reflect variable social status or specialization. Detailed geoarchaeological field recording of deposits produced a high-resolution view of prehistoric activity and temporal change. One methodological goal was to address
previous limitations with Northwest Coast faunal sampling, where major differences in excavation volume and mesh size preclude direct comparison of taxonomic representation of different animal classes (e.g., sea lions to herring). Field sampling was explicitly designed to allow for integration of all classes of faunal data (birds, fish, mammals, and invertebrates) and obtain a high-resolution picture of faunal change. One 10-liter bucket of sediment from each uniquely defined deposit was water-screened through graded mesh (down to 1/8"), while additional buckets from the same deposit were retained but treated less rigorously. Our presentation reviews the efficacy of this approach for addressing a range of questions, based on faunal remains from one house.

Buttles, Palma (Carnegie Mellon University/Software Engineering Institute) and Fred Valdez (The University of Texas at Austin)

[31] An Archaeological Snapshot in Time and Space: Colha and the Preclassic Communities of Northern Belize

Since its original recording in 1973 by Normand Hammond, Director of the British Museum-Cambridge University Corozal Project, the site of Colha has experienced a long (17 seasons) and diverse history of multi-disciplinary investigation. The results of these efforts have greatly contributed to the understanding of the biophysical Preclassic environment of northern Belize, the people who inhabited and manipulated it, the cultural, economic, and ideological systems that sustained it, and the material culture that functioned within it. In this paper we will compare and contrast the Preclassic community of Colha with its northern Belize neighbors to create a snapshot of the Preclassic regional landscape.

[114] Geoarchaeology and the Search for the First Americans

When did humans first settle the Americas? This question has eluded science for over a century, yet today we are closer to the answer than ever before. The debunked Clovis-First Hypothesis dogged our understanding of the truth for decades, and we now know that humans were in the Western Hemisphere for at least several millennia before Clovis. Despite outstanding gains, questions persist regarding fundamental aspects of the oldest sites in the Americas. For example: What processes have affected the distribution of their artifacts, geofacts, and ecofacts? What is the landscape context of the earliest sites and what was it like in the past? How old are they exactly? In many respects, geoarchaeologists are uniquely qualified to address these questions. In this paper, I present the history of geoarchaeology’s contribution to our understanding of American prehistory before Clovis and demonstrate a few parallels between the efforts that are taking place today and those that were undertaken over a century ago when geoscientists helped prove a Pleistocene human presence in the Americas. I also touch on how geoarchaeology can continue to take a leading role in the debate.

[155] Food Remains and Other Biological Materials from Abdominal Soil Samples: What Seeds and Other Biological Substances Can Tell Us about Historic-Period Dietary Consumption Patterns and Medicine

Soil samples collected from the abdominal regions of historically interred individuals provide a wealth of information about past food consumption, and also about potential medicinal uses of certain plants as folk remedies during the historic period. This paper presents data about the seeds, fruits, and other biological materials that have been collected from flotation samples from several cemeteries in Kentucky and West Virginia. The presence of certain seeds and fruits, such as raspberry/blackberry, can almost certainly be attributed specifically to dietary consumption, whereas the presence of others, such as nightshade, may have been from medicinal use. Possible dietary and medicinal uses of a variety of plants found in the southeastern United States are explored, and recommendations for collection strategies are presented.
Geomorphology of the Pipes Wash Fan: Implications for Early Site Preservation near Emerson Lake, California

Archaeological investigations conducted over the last 15 years in the Emerson Lake training area at the Marine Corps Air Ground Combat Center outside Twentynine Palms, California have revealed a number of Early-Middle Holocene sites distributed across the terminal portions of the Pipes Wash Fan, an expansive alluvial landform south of the Emerson Lake playa. This poster summarizes past and recent geomorphologic data for this area, highlighting recent investigations demonstrating the presence of localized buried surfaces that have the potential to preserve early archaeological sites. This potential is discussed in the context of millennial-scale changes in climate, particularly with regard to how these changes impacted water and associated resource availability.

Modeling Territorial Ranges and Spatial Organization of Late Pleistocene Hunter-Gatherers in the Southeastern Levant

This talk explores the nature of hunter-gatherer spatial organization during the terminal Pleistocene in the southern Levant. Archaeological research has demonstrated that both the western more forested areas and the surrounding steppe grassland and desert witnessed substantive occupation 21,000-15,000 years ago. This research study focuses primarily on exploring daily foraging ranges and potential annual territorial ranges associated with major base camps/aggregation sites in the steppe-desert region of east-central Jordan. Daily foraging ranges are modeled using least-cost GIS analysis that uses kilocalories as currency, and assuming individuals return to the base camp by the end of the day. The study also employs GIS-based landscape analysis to explore territorial ranges and boundaries, with the objective of generating multiple scenarios that can be tested with future research. The talk concludes with a consideration of social agency, supra-regional interaction, and how spatial patterns may have varied within the southern Levant.

Byrne, Chae (University of Western Australia) [244] Issues in Archaeobotanical Recovery and Sampling within a Terminal Pleistocene Cave on Barrow Island, NW Australia

Anthrocology (wood charcoal analysis) can generate valuable data surrounding past relationships between people and plant communities. This paper will discuss the preliminary identifications of charcoal fragments recovered from the first field season at Boodle Cave, Barrow Island, northwestern Australia. Analysis of species diversity will provide insights into the changing vegetation of Barrow Island as it transitioned between a high range on the extensive northwest shelf towards its current status as an island. There are proxy archaeological signatures (e.g., flakes from edge-ground axes and locally extinct fauna) to indicate the now drowned-coastal plain hosted very different assemblages to the spinifex dominated ones found on Barrow island today.

Byrne, Fergus (Institute of Archaeology, UCL), Tomos Profitt (Institute of Archaeology, UCL, London), Adrian Arroyo (Institute of Archaeology, UCL, London) and Ignacio de la Torre (Institute of Archaeology, UCL, London) [255] Bipolar Experiments with Quartzite from Olduvai Gorge (Tanzania)

An ongoing experimental program with raw materials locally available at Olduvai Gorge (Tanzania), aims to replicate the lithic technology of Oldowan and Acheulean assemblages from Beds I and II. In this paper, we focus on bipolar experiments carried out with quartzite from Naibor Soit, an inselberg close to some of the most relevant assemblages from the eastern side of the Olduvai paleo-lake. Our experiments compare free-hand with bipolar flaking using a range of interrelated techniques and aim to discern the features on flakes and cores that distinguish both techniques. Overall, our target is to set analytical criteria to better identify and understand the flaking methods employed by the Lower Pleistocene knappers from Olduvai Gorge.

[342] A Spatial Analysis of Surface Artifacts from the Ripley Site: An Iroquoian Manifestation on Lake Erie

The Ripley Site (NYSM 2490) in western Chautauqua County, New York, has garnered interest from archaeologists for over 100 years. Situated on a bluff overlooking Lake Erie, this Late Woodland through Protohistoric Iroquoian site has long been recognized by the scholarly and avocational communities; however, the site’s function remains problematic. In an attempt to address this and other issues, GIS is used to identify the spatial patterning of artifacts recovered during a recent surface survey and mapping project.

Cable, Charlotte (Michigan State University)

[67] Tombs in Time and People in Space: Making sense of the Third Millennium B.C. Hafit-Umm an-Nar transition in North-Central Oman

In current explanations of 3rd Millennium B.C. Oman there is simultaneously a recognition of the Hafit as part of the Umm an-Nar culture and a sense that it is somehow distinct from the Umm an-Nar period that followed. I argue that the developments of the Umm an-Nar period rest solidly on Hafit creations of social, political, and economic solidarity and heterogeneity – but that the Umm an-Nar culture eventually extends beyond its foundation. Referencing Hafit practices that consolidated group identity while maintaining local autonomy was critical during the Umm an-Nar period, when communities concentrated on local resource acquisition as a strategy for access to broader resources. In spite of this, the construction and maintenance of Umm an-Nar “towers” in oases such as Bat and ad-Dariz South, and the increasingly complex mortuary tradition, suggest that local groups in the Umm an-Nar period may have experienced difficulty in maintaining a worldview of regional solidarity. Using the Wadi al-Hijr in north-central Oman as a case study it is possible to follow these broad changes across the 3rd Millennium B.C.

[189] Descubrimiento de Tumbas de Tiro Selladas en Bolaños

Tumbas de Tiro selladas en la Cultura Bolaños, Jalisco, Mexico.

El hallazgo de 3 tumbas de tiro selladas dentro del centro ceremonial del sitio de El Pirión perteneciente a la cultura Bolaños permitió conocer el patrón de comportamiento regional de esta singular costumbre funeraria. Con base en ellas se logró entender las tumbas de La Florida y de Pochotitan todas ellas saqueadas. Las tumbas de tiro selladas proporcionaron en conocimiento de la colocación y orientación de los individuos dentro de la cámara; de los objetos de ofrenda y gran parte de la ideología religiosa.

Cadeddu, Francesca

In this paper, we introduce a spatial analysis (i.e., viewshed analysis and Thiessen polygons) of GIS data on the settlement patterns of the Nuragic civilization with the aim to perform a test of the major hypothesis proposed by scholars concerning the social organization of the Nuragic society, the sistema cantonale (cantonal system). With a geoarchaeological approach and a multidisciplinary perspective this paper points out new aspects in the settlement strategies and provides new data and an insight into the social, political and economic organization of the Nuragic civilization, a long-lasting culture that existed in Sardinia (Italy), from the Middle Bronze Age (ca. 1600 B.C) to the first Iron age (ca. 800 B.C.). With the use of the Earth Observation (EO) methods and the GIS platform, in addition to the appraisal of the parameters acquired with the reference work, we reconstruct for the Nuragic civilization a hierarchical settlement strategy confirming the hypothesized cantonal system. Its organization lies on the existence of territorial systems, formed by interconnected communities that share common attributes in their economic and settlement strategies. Our results allow us to reconstruct the social and political organization of
complex chiefdoms during Sardinian Bronze Age.

Cai, Yan (University of Pittsburgh)  
[51] Native or Foreigner? The Craft Organization of the Qin-Han Empire  
Research presented here focuses on the economic organization of tile production from the Warring States period through to the early Han Dynasty. This research reveals how the first Chinese empire was able to control such a large territory as it did, by analyzing the production of tile endings in different cities, namely Yong, the capital of the Qin Dynasty, to three frontier sites: Suizhong, Minyue, and Shouchun, in order to determine to what extent these industries were in fact under political control. The result of the comparative analysis indicates that Yong’s workers were mostly professional craftsmen of the official manufacturing system of the empire, and their production had the highest degree of craft standardization. Suizhong’s workers were foreigners who were the common people in the center of the empire. Therefore, their techniques were unprofessional and the degree of standardization was lower. Shouchun’s workers included native workers and foreign craftsmen. Foreign craftsmen had higher degrees of standardization whereas natives had lower. Minyue Wangcheng’s craftsmen were all native and the degree of standardization was lowest. These finds suggest that Qin-Han dynasties had different levels of economic control across the empire’s territory.

[67] Disparities in Health: An Investigation into Mobility and Dietary Impacts on Disease Prevalence in Two Wadi Suq tombs at Ra’s al-Khaimah, UAE  
Human migration across the Persian Gulf undoubtedly influenced the lifestyle of local Bronze Age populations in the Oman Peninsula and may have introduced new pathogens impacting health. However, few bioarchaeological studies have addressed the response of the human body to migratory stressors. The aim of this study was to explore the relationship between mobility and health in the United Arab Emirates during the second millennium B.C. using both stable oxygen isotope analysis and skeletal indicators of pathology, specifically infectious and metabolic disease as well as dental developmental defects. Human remains from two Wadi Suq (2000-1300 B.C.) tombs at the Qarn al-Harf cemetery in the Emirate of Ra’s al-Khaimah were utilized in this assessment: QAH5 (MNI: 39) and QAH6 (MNI: 145). Due to preservation, only 16 teeth were available for biogeochemical analysis. A higher prevalence of cribra orbitalia, LEH, and non-specific new bone formation was observed at QAH6 (33%, 5%, 9%) than QAH5 (0%, 0%, 6%). Mean 518O ratios for QAH5 (27.8 ± 1.0o) and QAH6 (28.1 ± 0.5o) did not differ significantly. These results suggest disparities observed in disease prevalence are not a consequence of migration, but likely result from differences in subsistence strategies between those interred in these tombs.

[76] Cultural Heritage Education Programs in Brazil: Sharing Experiences with Local
Communities
The present work offers an overview of a series of educational activities performed, in many Brazilian cities, by the licensing company Gestão Arqueológica e Consultoria em Patrimônio Cultural (Archaeological Management and Consultancy in Cultural Heritage) on cultural heritage education. In this educational program, a group of professionals including performing and visual arts, archaeologists and historians—after attending training courses—carried out practical experiences in schools, cultural centers, adult literacy hubs and indigenous communities, amongst others, aiming at opening a dialogue with the local communities about the archaeological remains found during the studies realized in those regions and, also, sharing experiences concerning material and immaterial heritage in the region and its surroundings. The results are achieved through performing dialogued presentations and practical activities such as studies of the pottery material culture. Also, the local attendants are invited to perform dance and music from their own community. The whole set of activities proved to be highly synergetic, due to the active participation of the communities. Therefore, it became clear that all these people have a lot to be shared and they always offer an indispensable contribution to the development of the cultural heritage education programs in Brazil.

Callisto, Christina
[232] Women and Children of the Turpentine Era
The back-breaking gum industry was built on eighteenth century slave labor concentrated in the Carolinas where the pine trees made it a naval stores hub providing the tar and pitch that would seal and waterproof ships. As the Carolina trees were ravaged by the box-cutting methods used to collect the gum, slaves were sent farther south and west to the virgin longleaf pine forest of the Gulf States. After emancipation, freed black men and their families were continually drawn the industry and its constant needed workforce even as it evolved from naval stores to turpentine distillation. Census records indicate that black and white men and women were employed well into the twentieth century and documents reference children assisting with the family’s workload. While photographs often show older, usually black, men working, there are some that show the women and children who lived at the camps and often worked beside the men collecting and processing gum. These photos of members of both black and white turpentine families from the 1800s to the 1940s offer a window into the evolving quality of life within the social constructs of the era of this industry.

Camacho-trejo, Claudia and Ana Bravo (INAH-Zona Monumentos Arqueológicos de Teotihuacan)
[293] Iconographic Usage of Plumage in Teotihuacan
The Teotihuacan Proyecto de Conservación de Pintura Mural focuses on restoring and analyzing, both in situ and archive, over 60,000 mural fragments recovered from previous onsite excavations. The project aims to expand current knowledge and obtain new insights by restoring mural scenes that are yet, unknown to the public. Murals in Teotihuacan are a particularly important form of visual communication that reinforced the canons by which this great metropolis lived. Teotihuacan cosmology is expressed in pictorial art. Teotihuacan murals also serve as frames and backdrops to pictorial glyphs that are now the topic of major decipherment efforts. Today more than 15,000 mural fragments had been analyzed with impressive revelations as to new pigments and iconographic motifs. Operating within the framework of this project, this presentation will focus on the analysis of the usage of plumage in Teotihuacan mural art. In addition to headdresses and other items of personal adornment, plumage is also found on edgings known as cenefas. It is by way of this study and the revelations of new pigments that we are able to provide a chronology for the creation of the murals and enhance our understanding of the iconography utilized in the murals.

Camp, Anna (University of Nevada, Reno)  [262]  From Catlow to Klamath: Exploring Technology and Identity through Great Basin Textiles
Archaeologists have often used lithic artifacts as markers of change and adaptation in the Great Basin. While lithics play an important role in key technological changes, textiles also offer a diverse perspective on the past. Based on Direct Accelerated Mass Spectrometry dates and limited typological analysis, Catlow Twine textiles appear in the archaeological record around 9000 B.P. and continue into historic times. Through detailed analysis of Catlow Twine and ethnographic Klamath basketry, this research focuses on the continuities and discontinuities of textiles through time and space and explores how this type of material culture may represent an example of technological stability. This research adds to our understanding of Great Basin chronology, the movement of people and material culture, and ideas about identity as it is manifested through the archaeological record.

Campbell, Kendall  [54]  Discussant

The Shang royal hunt appears to be the beginning of a high elite practice that continued down to the last Chinese emperors—part sport, part pageantry and part rite of rulership. Nevertheless, the Shang royal hunt employed a suite of new technologies recently introduced from the Steppe—the horse and chariot—and bears at least a family resemblance to 2nd millennium B.C.E. royal hunts from across Eurasia. Yet the Shang version of this rite of pacifying violence operationalized not only imported technocultural complexes, but also local notions of animality and divinity. As a key practice of royal authority, along with war and sacrifice, the hunt was part of a larger complex of practices aimed at domesticating the wild, unruly and dangerous powers beyond and within civilization's horizon. At the same time, the royal hunt both acted upon and reproduced Shang notions of civilization and its exterior: the wild and the sacred.

Campbell, Stuart [249] see Healey, Elizabeth

Campbell, Sarah (Western Washington University) and Virginia Butler (Portland State University)  [290]  Modeling Dynamic Social Organization and Resource Use for the Tse-Whit-zen Village Site
Oral history, traditional ecological knowledge, historic records, and ethnographies offer archaeologists working in northwestern North America rich information pertaining to subsistence adaptations and social organization of native peoples in recent times. Misuse of ethnographic analogy projects specific organizational traits back onto ancient time periods, assuming a straight-line trajectory and gradual, incremental change. Prentiss and Chatters have argued for a fundamentally different approach that recognizes that multiple forms of adaptation/residential mobility strategies might exist at the same time, that transitions in time might be abrupt rather than incremental, and that trajectories might include short-lived “experimental” forms and reversals. Acceptance of this model implies that we might find novel configurations in the past, requiring that we build models of social and subsistence organization from the bottom up, from archaeological data. Our research concerning use of animal resources by inhabitants of the Tse-Whit-zen village site on the Strait of Juan de Fuca approaches social organization over the last 2,000 years as dynamic and flexible, and responsive to short and long-term environmental change. We use ethnohistoric information as a source of models for developing alternative hypotheses about how social organization, ownership, and management of resources intersected, rather than projecting a specific structure.

Campetti, Casey [233] see Ford, Ben

Founded in 1815 when the region was still part of Missouri Territory, Davidsonville, Arkansas served as
the county seat for Lawrence County until 1830. It was the earliest planned community in Arkansas. Spurred on by land grants from the Spanish government, provision of land by the U.S. government to veterans of the War of 1812, and those displaced by the New Madrid earthquakes of 1811-1812, EuroAmerican settlers poured into northeast Arkansas during the early years of the nineteenth century. Archaeological excavations at Davidsonville by the Arkansas Archaeological Survey from 2004 to 2009 reveal significant differences from French settlements in Missouri and Arkansas.

Canilao, Michael Armand (University of Illinois at Chicago)

Landscape and Settlement Archaeology Methodology in the Cordillera Region of Luzon, Philippines

Island Southeast Asia presents some of the most challenging landscapes for archaeological investigations due to the high level of landscape modification from volcanic activity, earthquakes, monsoons, and high rainfall with consequent intensive erosion and downslope deposition of loosely held tropical soils as processes that are clearly exacerbated by human agricultural and building activities. This paper presents a case study for landscape archaeology from the Cordilleras of Luzon Island in the Philippines, where high angle slopes formed through an active plate subduction of the South China Sea plate creates erosional landscape that challenges the Law of Superposition. Given the lack of standing architecture in any prehistoric phase of human occupation in the Philippines, systematic regional survey and careful spatial mapping of durable artifact clusters are key to locating settlements, but it is difficult to develop archaeological settlement maps that reflect actual ancient occupations in their primary human depositional contexts rather than artifacts “creeping” on the surface in an erosional context. The study presented here shows that regional settlement surveys that take advantage of historical data on landslides, floods, and other factors (e.g., Landslide and Flood Susceptibility Maps of the Philippines by the Mines and Geosciences Bureau) make surface archaeology more productive.

Canipe, Courtney (East Carolina University) and Megan Perry (East Carolina University)

Exploring Quality of Life at Petra through Paleopathology

The ancient city of Petra, Jordan, capital of the Nabataean kingdom from roughly the 2nd century B.C. to 2nd century A.D., has attracted ongoing archaeological research since the early 1900s. However, much of this work has focused on the site’s architecture, leaving many unanswered questions concerning what the quality of life was like for Petra’s inhabitants. This poster provides a picture of health and quality of life of individuals buried on Petra’s North Ridge (n = 38) during the 1st century A.D. The North Ridge tombs are hypothesized to contain the non-elite segment of the population, as opposed to the elites buried in the monumental carved tombs for which Petra is famous. Skeletal analysis included macroscopic observation of pathologies along with assessment of age and sex profiles of the sample. This evidence clearly shows that non-elite individuals at Petra suffered from few conditions that would result in bone pathologies, such as infection and malnutrition, with degenerative disorders, primarily osteoarthritis, the most common pathology observed. Therefore, Petra appears not to present the picture of a dirty, disease-ridding city of antiquity.

The Characterization of Obsidian and Its Application to the Mediterranean Region—and beyond

We recall the origins of our 1964 paper and its reception at the time and review the application of analytical studies of obsidian characterization over the 50 years since then. We review briefly the procedures by which we chose trace-element analysis, originally by Optical Emission Spectroscopy, as a procedure for what we termed the “characterization” of obsidian, and the numerical procedures which showed Barium and Zirconium as usefully indicative elements for the primary separation of the data. The Mediterranean sources were effectively characterized, and those of Turkey soon shown to be crucial for the understanding of the obsidian trade in the early Near East. Subsequently applied analytical and quantitative procedures are briefly considered.

Interaction Effects among Bone Fragmentation and Screen Mesh Size in the Measurement of
**Taxonomic Relative Abundance**

In earlier work, I have developed separate mathematical models of the effects of screen size and bone fragmentation on zooarchaeological taxonomic abundance measures, and I have presented experimental data on the relationship between fragmentation and taxonomic abundance. Here, I integrate the two separate models and present experimental data on the interacting effects of fragmentation and screen size on taxonomic relative abundance. Counterintuitively, both the model and the empirical data demonstrate that the use of smaller-mesh screens does not necessarily lead to more accurate measurement of taxonomic relative abundance (e.g., through abundance indices); under certain conditions, larger-mesh screens, which undoubtedly result in greater loss of identifiable specimens, may also result in more accurate relative abundance measurement. Most important, this exercise points to steps that can be taken to determine whether the relative abundance values observed using a given screen mesh size may be greatly in error. This can be determined through the consistent use of nested screens of different sizes.

[121] *Inka Style Materials in a Provincial Mining Setting: Evidence from Los Infieles, North-Central Chile.*

Prehispanic Andean societies relied on mining to obtain highly valued minerals used in the production of prestige goods that were critical for the reproduction of religious and political institutions. Over the past decade, archaeological studies have begun to expand our largely historically-based understanding of Inca mining activities in the southern Andes. In this paper, I examine Inca style materials recovered from sites in Los Infieles, a mining complex located in north-central Chile (Coquimbo Region) centered on the extraction of chrysocolla and opaline silicas for lapidary purposes. These materials include fragments of Inca style pottery from mining facilities documented during a recent archaeological survey and Inca ritual paraphernalia (metal and shell figurines) from a ceremonial platform looted in the late 1950s. Exploring the physical characteristics, distribution and social roles of these materials, I argue that while the ceramic assemblage provides information about the production, functions, and distribution of both local and Inca style vessels at the sites, the ritual cache highlights the political and ideological significance of state religious practices within mining contexts. Both lines of evidence provide insights into the overall organization of the mining operations at Los Infieles and the relationship between the mining community and the Inka state.

[279] *Socio-Political Complexity and Early Urbanism in the Lowland Maya Area*

Among the greatest challenges of the study of Formative-period Mesoamerica is the explanation for the causes of socio-political complexity. It is by now a commonly held notion that by the Late Formative period, a handful of coeval regional states existed in Mesoamerica. In the specific case of the southern lowland Maya area, by 200 B.C., its inhabitants were living in large urban centers that functioned as regal capitals from which an ajaw governed a centralized regional state. In general terms, those social and political interactions bespeaking institutionalized power relations both between and within groups developed long before they became archaeologically manifest. Nevertheless, evidence for precocious complexity per se—such as the existence of and justification for “natural lords” dating to periods earlier in time than scholars originally thought—renders the causal processes of that complexity no less nebulous. In fact, evidence of precocity only forces scholarly focus onto even earlier and less understood periods of time. Consequently, to interpret the developments of the Late Formative period in the Maya area, this paper will investigate the processes that led to widespread urbanism and socio-political complexity.

Cap, Bernadette (University of Wisconsin-Madison)

[252] *A Socially Constructed Plaza: Evidence of Marketplace and Ceremonial Activities during the Late Classic Maya Occupation of the Buenavista del Cayo East Plaza*

The plaza was an integral design element of Classic Maya site centers and was significant to society because of the activities conducted within them. There is scant direct documentation in Classic period Maya artwork or texts of what took place in plazas, but in other areas and throughout time, urban plazas have been host to a variety of activities that shape the social, ideological, economic, and political fabric of
society. Recently, researchers have begun to examine Classic period occupation of Maya plazas through empirically-based studies, but have been met with several methodological challenges. In this paper, I present research from the East Plaza of Buenavista del Cayo, Belize, which addresses the issues involved in identifying plaza activities, specifically through the development and application of a multiscale configurational approach. The result of this intensive investigation is the identification of a Late Classic marketplace and ceremonial activities in different sectors of the East Plaza. Individually, these activities influenced the social, economic, and ideological structure of the Buenavista settlement. Collectively, these findings illustrate the vital role of the public plaza in Maya society.

[285] Termination Rituals at Panquilma

The abandonment of settlements and regions, its causes and consequences, are subjects that have been broadly studied by archaeologists. Several approaches can be taken in order to establish what mechanisms were involved in these processes, and how they can be seen through the archaeological record. One of them involves the relationship between termination rituals and site abandonment, seen through specific cases of intentional destruction. Many of these termination events have a strong ritual component and might have been triggered by unexpected social, political or economic contexts. In this paper I will present evidence of selective burning and destruction associated with monumental architecture found during excavations at Panquilma, a Late Intermediate Period (900-1400 A.D.) settlement located in the central coast of Perú. I argue that this evidence suggests that termination rituals, associated with a partial abandonment of certain structures, might have occurred at specific areas within the site.

[23] Late Pleistocene Highland Foraging in the South Central Andes

In this paper we review current models and evidence regarding the colonization of the south central Andean highlands. Existing models argue that ecological (topography and glaciers) and biological (hypoxia) constraints acted as barriers that prevented human settlement above 3500-2500 m above sea level before the onset of the Holocene (~10,000 cal. B.P.). These models not only disregard the potential variability of human biological and cultural adaptability, but also fail to recognize increasing evidence of highland occupations dated to the late Pleistocene. Our ongoing interdisciplinary research provides insights into the timing and paleoenvironmental context as well as the subsistence, and mobility strategies, technology and the different activities practiced by the earliest highlands foragers in the identified sites of the Bolivian and northern Chilean highlands.

[328] The North Dakota Man Camp Project: The Archaeology of Workforce Housing in the Bakken Oil Patch of North Dakota

Since 2007 the western part of North Dakota has experienced an economic and population boom associated with the extraction of shale oil from the massive Bakken formation. While this area had experienced both agricultural and oil booms in the past, nothing in the region's history had prepared the communities and infrastructure for the transformation brought about by hydraulic fracking. The North Dakota Man Camp Project documents the material and social conditions of workforce housing in the Bakken. From corporate installations that resemble mobile hotels to RV parks, infilled small towns, and squatting off the grid, workforce housing has presents the material signatures of community building throughout the oil patch. The rapid expansion of short-term housing and populations in the Bakken has outstripped historical and document-based methods for describing this change. This paper presents a preliminary report on how the archaeology of the contemporary past has provided an alternate method for
understanding the assemblages, architecture, and settlement patterns of associated with workforce housing in the Bakken boom.

Caramanica, Ari and Michele Koons (Denver Museum of Nature and Science) [149] Living on the Edge: Precolumbian Habitation of the Desert Periphery of the Chicama Valley, Peru

The desert borders and dry ravine washes that surround and often encroach upon the irrigated river valleys of the north coast of Peru played an integral role in precolumbian history. The Chicama Valley Land-Use Survey (CVLS) identified multiple sites and archaeological features in the desert landscapes of Río Seco de Paijan, Playa Mócan, and Culebra on the borders of the irrigated Chicama Valley. Our team discovered that in spite of the now-harsh environment, this landscape was once densely occupied and cultivated almost continuously from the Early Horizon Period (1000–200 B.C.) to the Colonial Period (A.D. 1532–1824). By combining geomorphological, paleobotanical, and archaeological evidence, we have begun to establish a horizontal chronology for these areas. Finally, after placing this evidence in a greater regional archaeological context, we conclude that instead of backward, impoverished, diminished versions of the political, economic, and ritual centers of the inner Valley, these "hinterlands" or desert borderlands were in fact crucial landscapes of production in the pre-Columbian past.

Carballo, Jennifer (Department of Anthropology, Harvard University) [112] Social Interaction and Variation in Central Tlaxcala, Mexico: An Analysis of Ceramics from Two Early Village Societies

Similar motifs appear on pottery throughout Mesoamerica during the Formative period, often depicting symbols associated with Olmec iconography, yet we understand little about how they were used or what they signified. I investigate pan-Mesoamerican pottery motifs during the Middle Formative period, by documenting differences in vessel use and vessel decoration at two small villages near Apizaco, Tlaxcala, dating from 900 to 500 B.C. I examine the designs and distribution of motifs at the sites of Amomoloc and Tetel, and compare them to designs from other sites across Mexico, providing evidence for how Tlaxcala's earliest sedentary communities participated in a network of early Mesoamerican societies exchanging goods, ideas, and motifs, during an important period of increasing sociopolitical complexity before the appearance of the first cities and states in Mexico. Did this shared style function in competitive display and/or signal participation in reciprocal networks of exchange and cooperation? What patterns of variation can we detect in the representation and use of the Middle Formative style? I approach these questions at multiple scales, from the individual motif to the ceramic vessel, community, and regional levels.

Card, Jeb (Miami University) [72] How Much Technology Transfer Occurred in Early Colonial Central America?

Discovering evidence of technology transfer and cultural change has been key goals of investigations at Ciudad Vieja, El Salvador. The site of the first permanent Spanish settlement in the country has provided important evidence for cultural change and shifting identities, but technological transfer has seemingly eluded us. European technology such as iron working and indigenous technology such as pottery production were practiced at the site. Technological transfer between these two worlds has not been identified beyond stylistic influence in ceramic form and use. The best evidence for technological change within the approximate three decades of occupation is a shift in Mesoamerican pottery production from a diverse set of potting techniques (mirroring the diversity of the resettled population) to a more homogenous site-wide technological style (suggestive of changes in social practices and networks among a generation of potters born at the site). The recent discovery of what may be a locally and oddly produced olive jar may represent experimental adaptation of local materials by a European potter, and not broader evidence for technological transfer.

Cardinal, J. Scott (New York State Museum)  
Although notional referents of social “norms” and “normative forces” are commonly a priori predicates of the very concept of culture within the social sciences, current conceptualization of normativity is insufficiently realized and inadequate in the form in which it is typically applied in archaeological interpretations. The concept of normativity is broadly utilized in philosophical and sociological literature, but the prevailing definitions and their associated discussions regarding beliefs and justifications are not directly applicable to archaeological theorization. A robustly operationalized formulation of normativity and its related concepts is necessary in order to utilize normative effects in an explicit evaluation of their influences on past behaviors through archaeological correlates. An archaeological formulation of the concept of normativity would require a degree of specificity in definition and ontology that has not been fully developed for the concept within the social sciences. Norms are not simply pervasive social rules or pre-existing mental templates by which the social is enacted. Such constructions require a paradoxical presumption that norms precede social interaction. If normativity is instead conceived as a contingent locus or boundary of agent-group interaction, an effect rather than a cause, then a new set of definitions and operative social mechanisms are readily derived.

[148] A First Look at the Early Holocene Assemblage from LSP-1: A Stratified Rockshelter in Oregon’s Warner Valley  
Since 2010, the Great Basin Paleoindian Research Unit (GBPRU) at the University of Nevada, Reno has been excavating a modest rockshelter in Oregon’s Warner Valley. Work there has revealed an extensive early Holocene occupation consisting of a well-preserved faunal assemblage dominated by leporids, marine shell beads, Great Basin stemmed and foliate projectile points, abundant ground stone artifacts, and assorted other stone tools including one of the only crescents found in a well-dated context in the Great Basin. We present an overview of our work and focus on the site’s stratigraphy and our efforts to radiocarbon date the deposits, provide brief summaries of the lithic and faunal assemblages and what they reveal about late Paleoindian lifeways in the northern Great Basin, and place our findings within the broader context of current research in the region.

[164] Chacmool: Who Was that Enigmatic Recumbent Figure from Epiclassic Mesoamerica? Reposing the Question  
The monumental stone sculptural human form known as a “Chacmool” first appeared in Mesoamerica late in the Epiclassic Period (650–900 C.E.), specifically in Toltec Central Mexico (Tula), in Yucatan at Chichen Itza in particular, but spread as far as the Tarascan region of Michoacan and El Salvador. Since such uniquely-posed male sculptures were first imaginatively named “Chaacmol” by Augustus Le Plongeon—inspired by one famous example he excavated at Chichen Itza in 1875—their true function, identity, and region/culture of origin have remained largely subjects of speculation. Although they were still in use at the time of Spanish contact in Aztec Tenochtitlan, no obvious recorded names for these enigmatic sculptures nor the identity of the single male figures represented have ever been recognized in any Mesoamerican language. However, several lines of evidence and argument have convinced most scholars that they were an innovation for a specific type of sacrificial altar—a Cuauhxicali—associated with quite ancient and pervasive militaristic cult practices of human heart and blood sacrifice. A new interpretation of the form and function of the Chacmool is offered based on a comprehensive re-evaluation of the data along with new archaeological evidence.

Geoarchaeology of a Cave Vestibule in Southeastern Kentucky

In March 2013, a small group of archaeologists and cavers conducted fieldwork in the cave vestibule of an archaeological site in southeastern Kentucky. Goals of the investigation were to assess the integrity of archaeological deposits, identify geomorphological, anthropogenic, and biogenic activity, and determine the antiquity of prehistoric use by Native American populations. A variety of minimally invasive methods were used, including cleaning and recording of an already exposed profile wall, systematic columnar collection of sediment samples for particle size, organic content, and elemental analyses, extraction of in situ sediment samples for micromorphological analyses, and collection of nut charcoal to date a pit feature in the profile wall. The results show that there are still intact deposits within the vestibule, with organic, elemental, and micromorphological analyses suggesting that human activity was more prolific in the upper portion of the profile than the lower portion. Radiocarbon dating of the pit feature shows that humans were using the cave by at least 6000 years ago.

Evidence for Upland Origins of Indigenous Plant Domestication on the Southern Cumberland Plateau of Tennessee

While Eastern North America is among the established centers for indigenous plant domestication, where this process began on the landscape remains elusive. Models exist for both uplands and river valleys. We present data from two sandstone rock shelters representing different landscape positions from the southern Cumberland Plateau in Franklin County, Tennessee. By considering the macrobotanical data and the implications for annual foraging rounds, the availability of wild plant foods, and the initial appearance of both wild plants and domesticates, we suggest cultivation was initiated in upland settings.

Carn, Timothy (Indiana University of Pennsylvania)

Uncovering Native American/Colonial Relations on the Western Frontier during the French and Indian War through a Comparative Study of Material Culture Remains

The French and Indian War was a tumultuous time for Native American politics. The period witnessed the frequent fragmentation and coalescence of loyalties among different groups seeking to maximize their chances of survival by allying themselves with the strongest colonial force. Aughwick, a trading post on the then-western frontier of Pennsylvania bore witness to these complex Native American/Colonial interactions. As the war intensified, it became a place of shelter for Native American groups. As the conflict moved closer to the site, George Croghan, the owner of the property and captain of the fort, fortified it. No record of Native American involvement in the fortification of the trading post survives. To determine involvement, a comparison of material culture remains of this site to a contemporary fortified Native American village and a strictly British constructed fort was made. This comparison helped determine markers of Native American identity (e.g., modified trade goods and ornamentation). These markers were found to be more abundant at Aughwick than the British constructed fort. This shows with certainty that the Native Americans living at Aughwick helped fortify the trading post. This reinforces the underappreciated and often-overlooked political agency exercised by Native Americans during this conflict.

Grand Parallel: A Consistent Latitude of Caddo and Late Woodland Multimound Centers from Eastern Texas to the Lower Mississippi Valley

During the Late Woodland sub-period between A.D. 400 to 1200, six major multi-mound centers
distributed from eastern Texas to the Mississippi River were established on a consistent latitude of 31.6 degrees north. Few multi-mound centers were founded south of the latitude during the sub-period. The six sites comprising the pattern include, from west to east: the Caddo sites George C. Davis and Washington Square in eastern Texas; Troyville, the Elkhorn/Frogmore/Churupa three-mound cluster, and Deprato in Louisiana; and finally Emerald Mound in Mississippi. Troyville, a major population center during the Baytown period from A.D. 400 to 700, appears to be the oldest of the sites at such a latitude. After mound-building was discontinued in some areas, there is evidence, at least in the Caddo area, that major population centers continued to be established on the same latitude as the mound centers into late prehistoric or early historic times. The pattern, designated the Grand Parallel, is inferred to represent the macro-scale manifestation of a fundamental east-west organizational principles evident in many aspects of the Late Woodland and Caddo sites and social organization.

[230] Plastic Litter as Material Culture: The Applied Archaeology of Stream Pollution
Plastic deposition in rivers, lakes, and oceans is a pervasive problem at multiple geographic scales. Much scholarly and public attention has been devoted to plastic deposition in marine contexts, such as beaches and mid-oceanic gyres, which represent the endpoints of a systemic pollution problem. Less is known about inputs of plastics into local hydrological systems, such as streams, where pollution can be prevented and where littering behaviors frequently occur. Behavioral archaeology is an ideal framework for learning about the factors that lead to littering through consideration of trash as material culture (e.g., garbology). A general disconnect between the short use-lives of plastics and their long-term preservation in the environment exists; that is, plastics tend to endure once they leave the cultural context. The environmental/archaeological context of plastics in streams incorporates hydrological and other environmental variables that affect debris once it becomes deposited. We sampled litter from a variety of stream sites to make inferences about the behaviors that induce littering events along Hickory Creek in Denton, Texas. Linking characteristics of pollution to behaviors is a vital component of developing effective cleanup and prevention strategies.

[277] Dead Wrong: Investigations Concerning Two Eastern Structures at Las Cuevas, Belize
The surface site at Las Cuevas has been investigated for two seasons, but as yet no sealed deposit, burial, whole vessel, or any other type of datable cultural material has been recovered. The 2013 season was designed to excavate the most promising structures in hope of providing some definitive dates. Relying on previous patterns from the nearby site of Caracol, two eastern buildings were chosen for the high probability of having sealed datable deposits. The first eastern structure excavated was located in the core center, impressively placed directly above the Las Cuevas entrance. It proved to be an amazing example of architecture, with three building phases, well preserved, showing impressive stone work: staircases, floors, terraces, but not one deposit, vessel, cache or bone. The second and much smaller eastern structure was situated on a massive (28 x 24 m) platform. Architecture was immediately encountered and the modest mound produced not only special deposits, but the first burial at Las Cuevas. While patterns from the neighboring site of Caracol can be helpful in predicting excavations, they can also be surprising wrong, especially when focused on a research design question.

[339] Interaction and Integration on the Northern Aztatlán Frontier in Sinaloa
Utilizing data derived predominantly from investigations at El Ombligo, Mochicahui and Rincón de Buyubampo, we examine the northernmost extension of the Aztatlán archaeological tradition incorporating the Culiacán region along with the evidence of integration and interaction with the
neighboring Huatabampo and Serrana traditions in northern Sinaloa and southern Sonora. We propose that the Culiacán region played an instrumental role in Aztatlán interaction with the Guadiana branch of the Chalchihuites tradition in Durango and suggest that the transmission of objects and ideology beyond the northern Aztatlán frontier was facilitated and enhanced by the existence of a shared Cahitan language continuum that extended along the western slope of the Sierra Madre Occidental from the Río Piaxtla to the international border.

Carr, Philip (University of South Alabama)

[76] Team-Based Learning in an Undergraduate Archaeological Method and Theory Course

Arguably, active learning has a long place in the undergraduate curriculum of archaeology students because of the importance of field schools. The use of active learning, an instructional approach that emphasizes the importance of learner engagement and that is often contrasted with traditional lectures, is likely much more variable and sporadic, whether in an introduction to archaeology course or an advanced course such as archaeological method and theory. Forms of active learning including discussion and short written exercises are common strategies used by some instructors for decades, and others such as think-pair-share and team-based learning are more recent. Archaeologists can certainly engage students in the classroom with flintknapping or artifact identification activities. The use of active learning and these specific examples begs the question, which activities are appropriate? Here, this question is addressed for an undergraduate archaeological method and theory course with a focus on team-based learning. In order to do this, the first step is to engage in backward design by addressing, “what do we want our students to be able to do upon completing this course?” Here, archaeology textbooks are reviewed to answer this question and to determine which activities aid in meeting course goals and objectives.

[183] An Ethnohistorical Foundation for an Archaeology of Prehistoric Woodland and Plains Native American Cosmologies of Death

Symbolically rich mortuary remains from prehistoric Woodlands and Plains societies in North America offer ripe opportunities for inferring past eschatologies when integrated with analogous Native ethnohistorical information. This research program has been weakened, however, by the lack of systematic characterization and mapping of historic Woodland-Plains eschatological knowledge. A survey of 204 narratives about the journey to an afterlife, drawn from 42 Woodland-Plains tribes, documents a huge suite of motifs (n = 527), their commonness, geographic distributions, and co-occurrences. Twelve distinct narratives or narrative segments, areally bounded, are revealed. A few individual motifs were widespread over the region but no comparable narrative was identified.

[180] Studies of Black-Gloss Pottery from Monte Pallano (Italy) IV: Multivariate analysis and interpretation

This is the last of a series of four papers that report multi-faceted studies of a collection of 200 sherds of black-gloss pottery (a type of fineware that was used for dining and wine consumption from the 5th century B.C.E.-1st century B.C.E.) excavated from the Monte Pallano ridge in the Abruzzo region of eastern Italy. The study region includes two distinct areas: a hilltop settlement and a nearby sanctuary precinct. Some of the ceramics were made locally; others made elsewhere. Here three data sets employing different methodologies—macro morphology, petrography, and X-ray fluorescence—are combined and analyzed as a whole with multivariate statistical techniques. By comparing the fabrics of black-gloss ceramics from two adjacent, but functionally different, sites (hilltop settlement vs. sanctuary precinct) each with different loci of ceramic production (local vs. imported) the study aims to inform our understanding of patterns of trade and cultural exchange among the Samnites, Romans, and other peoples who populated this region of eastern central Italy in antiquity.

Investigating Isotopic Inter and Intra-Skeletal Variation in Lesionous and Non-Lesionous Tissues in Pathological Specimens from Nicaragua
The application of intra-skeletal sampling strategies were used to examine the degree of isotopic variation between lesionous and non-lesionous skeletal tissues from human samples obtained across Nicaragua. $\delta^{15}N$, $\delta^{13}C$ and $\delta^{18}O$ values in healthy bone and dentin collagen, as well as enamel apatite, were examined to discern the relative contributions of C3 and C4 dietary consumables to individual diet. These results were then compared to the isotopic values obtained from pathologically remodeled bone from within the same specimen, in order to discern the degree of dietary alteration observable during periods of bone remodeling. Samples were then evaluated for inter-group variation (between other diseased individuals, and among completely osteologically healthy individuals from the same sites), in order to evaluate what, if any, dietary differences existed between and among diseased and non-diseased individuals. This work contributes to the isotopic database documenting Nicaraguan subsistence strategies, their changes through time, and the impact disease has on socio-cultural subsistence practices.

Experimental Replication of Copper Production at the Gulkana Site, Alaska
Archaeological evidence and oral history attest to the presence of a native copper working tradition in the Southwestern Subarctic over the past millennia. Investigations have been carried out concerning the distribution of copper and its relationship to prestige of copper and production methods. Ethnographic records and material analysis indicate that hammering, annealing, and folding were used to produce a variety of goods from ticking bells, projectile points, to copper blanks used in trade. To expand on our understanding of copper artifact production and associated site formation processes, I have conducted a series of replication experiments recreating copper blanks and ticking cones by using methods and materials available in the past. These experiments shed light on the time and resources required to produce copper sheets and associated artifacts. They also provide information on the scrap and debitage, such as scaling, produced as a result of these activities. A comparison of the experimental results with artifacts from the Gulkana Site in Alaska, provides insights into native copper metallurgical innovation here and elsewhere.

Tuupaj: Ancient Maya Ear and Nose Ornaments as Artifacts and Signs
Ornaments worn in the ears and nose were among the semiotically richest articles of ancient Maya dress. Linked to wealth, vitality, and multisensory experiences of beauty, they also articulated with representational conventions in other media and with entrained, bodily habits and dispositions. Such ornaments served as markers of personal rank, ethnic membership, and—in the case of gods and their earthly impersonators—specific identity. This paper explores the meanings and social functions of ear and nose ornaments in ancient Maya societies. Drawing on archaeological and art historical evidence, it traces trends in the representation and material qualities of these artifacts over time.

Carter, Tara [198]
Fashionably Late: The Transformative Role Social Networks Play in Social Complexity and Secondary State Formation in So-Called Marginal Societies
Archaeological evidence from the Viking Age indicates a highly connected world that linked the societies
of Europe with North Africa, and the Middle East and yet this evidence has not been applied to the
development of secondary state formation in Iceland. Previous models have vacillated between those
that emphasize indigenous state development within an anemic environment, and those that emphasize
its purely derivative nature in a world of existing monarchical neighbors. The shared weakness of these
arguments is a presumed marginality, from an environmental and a social point of view. Using
applications from social network theory, this paper argues that Iceland’s connection to both a local as well
as a global economic network paved the way for social change. In fact, “coming late” onto the scene
allowed Icelanders to selectively develop fertile social relationships with multiple societies rather than
being locked into trade with a designated partner as was often the case among rural peasant merchants
back home in Scandinavia. Iceland, and societies like it, should not therefore be viewed as marginal in
any sense as these societies frequently managed a strong social connectedness that fostered exchange
and innovation, cultivating an environment fertile for social complexity rather than social stagnation.

[249] From Conservative to Cosmopolitan: Interrogating the Reconfiguration of Near Eastern Obsidian
Exchange Networks from the Epi-Paleolithic to Chalcolithic

It is well established that there were major differences in the use of Anatolia’s obsidian sources over time.
From the later Paleolithic to early Pre-Pottery Neolithic B we witness the almost exclusive use of four
sources, despite the fact that there are numerous obsidian-bearing volcanoes in Anatolia. The “big four”
comprise Golli Dag and Nenezi Dag (southern Cappadocia), plus Bingol and Nemrut Dag (eastern
Anatolia). While Cappadocian products were consumed by central Anatolian, Cypriot and Levantine
populations, Lake Van region obsidian was employed in south-eastern Anatolia and the eastern wing of
the Fertile Crescent. These circulation patterns were reproduced over millennia, a remarkable longevity (or
conservatism) of cultural traditions and regional connectivity. In the 1960’s Renfrew commented that
Chalcolithic obsidian exchange was far more “cosmopolitan,” with an increased range of raw materials
travelling over longer distances. These changes actually occur during the Late Neolithic with the first
appearance of northern Cappadocian obsidian in the Levant, together with the use of other Lake Van
sources, and obsidian from north-eastern Anatolia and Armenia. Here we discuss the major reconfiguration
of cultural traditions and the fragmentation of deep-time exchange networks in the context of regional
socio-political change more generally.

[255] Chimpanzee Technical Behaviors and Their Stone Tool Assemblages: An Archaeological
Contribution to Understand the Earliest Tools

The idea that archaeologists could be missing important archaeological records by having focused solely
on studying and analyzing the remains of human culture has recently become compelling. Chimpanzee
archaeology seeks referential modelling using interdisciplinary approach, combining tool-use field
experiments with natural observations, and studying different communities of chimpanzee tool-users
across Africa. By combining archaeological knowledge (technological analysis, actualistic
experimentation, surveying “off-sites” and older deposits than the ones known to have tools) with
primatological methods (direct observation of behavior, field experimentation, comparison of technological
communities/populations) these disciplines work to produce a theoretical framework to help explain better
the evolutionary origins of technology. We currently sought to further expand knowledge concerning
technology-related behavior, as this is, by far, the most difficult part of archaeological reconstructions. In
this paper we review our studies on wild chimpanzee technical behavior and their assemblages: (1)
regional variations across assemblages; (2) density and distribution of artifacts at tool sites (with possible
implications for predicting the size of archaeological areas and extrapolating possible group sizes); (3)
reuse of tool-composites and its implications for triggering unintentional knapping; (4) consequence of
multiple transportation events for producing assemblages; (5) quality/availability of raw material as
ecological constraints to technological development.

Carvalho, Milena (University of Louisville) and Jonathan Haws (University of Lou isville)

This poster presents the results of a comparative taphonomic study of two Pleistocene cave sites in
Portugal. The Gruta das Pulgas yielded several hundred bones from small mammals, birds, ungulates
and carnivores. The lack of artifacts suggests this was a natural accumulation with inputs from carnivores
only. At Lapa do Picareiro, the Early Upper and Middle Paleolithic levels are interspersed with levels that
do not contain artifacts but have preserved bones. The taphonomic study of both sites includes calculation of NISP and MNE for each taxon, as well as the recording of surface modifications, such as tooth scoring, tooth punctures, fractures patterns, cut marks, fracture patterns and skeletal element patterns. The results are then compared to help determine the agents responsible for the formation of the assemblages. The Picareiro assemblage appears to contain inputs from humans, carnivores and raptorial and scavenging birds.

Carver, Charisse (Arizona State University)

Frankish Ethnogenesis and Population History: A Bioarchaeological Perspective

The Early Middle Ages (A.D. 400-1000) of western continental Europe is a fluid and complex period of post-Roman transitions and emergence of nascent European nation states. Overwhelmingly the domain of medieval historians, archaeologists interested in Frankish ethnogenesis and population history are often confronted with (1) conflicting or biased written accounts; (2) material remains that are inconsistent with contemporary ethnohistoric documents; and (3) difficulties associated with working in regions subject to prolonged centuries of continuous human occupation. Consequently, this presentation will take an explicitly bioarchaeological approach to questions of Frankish population history and ethnogenesis. Specifically, I use model-bound biodistance analyses to estimate gene flow and genetic drift for a variety of early medieval Frankish sites in western Europe, assess how these parameters may have changed over time, and explore how they relate to processes of Frankish ethnogenesis. I argue that a commonly held view of long-term population continuity and/or small-scale elite-driven migration and acculturation processes obscures a more complex mosaic of population movement and settlement that parallel the development and eventual coalescence of Frankish ethnogenesis in the 9th–10th centuries A.D.

Landscape Phenology, Climate Variability and Agricultural Sustainability in the Northern Fertile Crescent: Insights from Regional-Scale Satellite Remote Sensing

While evidence of past climate change has long been invoked as a major force in driving both the emergence and collapse of complex societies in the Near East, few paleoenvironmental datasets provide sufficient temporal resolution to adequately assess the timing or severity of hypothesized climate events, while the actual impact of such events on ancient agricultural systems remains largely speculative. This paper presents results of a NASA-funded project that utilizes high-temporal resolution satellite data (AVHRR and MODIS) from the past three decades to reconstruct the spatiotemporal dynamics of seasonal and interannual environmental variability, or landscape phenology, in the northern Fertile Crescent. A high-resolution gridded precipitation dataset for the same time period further enables a nuanced perspective on how the totality of water resources influences cycles of plant growth and overall agricultural potential throughout the region. These data are analyzed against an archaeological site database, including more than 20,000 sites mapped through systematic analysis of 1960s-era CORONA satellite imagery. Analysis of the distribution of sites from various periods alongside evidence of associated relict agricultural fields challenges long-held notions regarding the land use history of the region and reveals new insights into the relationship between settlement sustainability and environmental change.

Stable Isotope Paleodietary Reconstruction of Teopancazco Teotihuacan

We sampled 39 molars from burials excavated in Teopancazco, Teotihuacan and performed isotopic analysis of 513C and 515N in tooth-dentine and 513C and 518O in enamel-apatite. The data was used to reconstruct the non-protein and protein intake of the diet of the individuals, using the bivariate carbon and the multivariate carbon and nitrogen stable isotope model. However since the models where developed and validated for bone apatite, to use the enamel data obtained we confirmed and calculated the difference between tooth and bone apatite (2.0o) in our population. The local population consumed a uniform whole diet with very C4 signal and differences in diets are related to immigrants from other geographic locations. During the most flourishing period, Xolalpan, there is a significant increase in the C4 signature of the protein and non-protein fraction of the diet. Concerning trophic levels we can clearly see five groups with different average 515NAIR, some of them unusually high. Archaeological evidence
supports the theory that population growth of this neighborhood and maybe of the great city was possible due to intensive maize agriculture that provided a stable and sufficient food supply and a surplus that could be stored in tunnels or fed to animals.

[116] On the Border: The Lithic Assemblages from the Trench Area of Cabeço da Amoreira Shell Midden (Central Portugal)

One of the most remarkable features of the new excavations at Cabeco da Amoreira shellmidden (Muge, Central Portugal) was the recognition of a series of Neolithic and Mesolithic horizons located just outside the mound limits. These, previously unknown, occupations were exposed in various test pits around the midden and, more strikingly, in a 1-x-12 trench where it was possible to confirm that a total of seven archaeological layers were formed during, and thus closely related with, the construction of the shell deposit. Hundreds of lithic materials, some ceramics, and two fire combustion features were recovered from this area. This paper will focus on the results of the techno-typological analysis of the lithic materials that has allowed us to build a diachronic framework for the occupations, detect a functional divergence between the Trench area and the shellmidden, and strengthen the argument of the use of the midden during Neolithic times.

Case, Dana

[285] Textile Production at Panquilma

During the 2013 field season, archaeological excavations were undertaken at Panquilma, an archaeological site dating to the Late Intermediate and Early Horizon periods (13th to 15th century) and located in Lurín, in the district of Cieneguilla, just outside of Lima. These excavations uncovered a significant number of textile artifacts, as well as tools related to the manufacture of textiles (such as spindle whorls and needles). Because textiles were an important part of pre-Columbian Andean society, playing a major role in social organization for Andean people, the textile artifacts found at Panquilma are a potentially important source of information about society there. Analysis of the textile artifacts found at Panquilma has been promising. This paper discusses the methods and findings of that analysis, focusing in particular on the contexts in which the artifacts were found, and the quality and abundance of textile-related artifacts in each context. Textile-related artifacts from several units are compared, helping to draw conclusions about which households were producing textiles, and what textile production meant for the status of these households within the social hierarchy at Panquilma.

[182] Bloody Creeks or Seasonal Residents: An Examination of Social Interaction in the Spur Cross and Skunk Creek Areas

Over the past several decades, Southwestern archaeologists have examined the role of warfare in contributing to social interaction patterning between the thirteenth and fifteenth centuries. In areas such as the Mesa Verde region, there is strong evidence of overt acts of violence; however, elsewhere in the Southwest, evidence of conspicuous violence is less clear. In central Arizona, archaeologists have suggested that sites located just north of the present-day city of Phoenix were constructed in highly defensible locations beginning around A.D. 1300, in response to increased social tensions. My paper therefore examines the settlement patterning of sites located in the Spur Cross and Skunk Creek areas to determine to what extent inter-site violence affected social relationships in those areas. Recent pottery sourcing work has shown that despite evidence of interaction between sites in those areas and Perry Mesa and the Phoenix Basin, no evidence of interaction between sites in the Spur Cross and Skunk Creek areas has been identified. Utilizing an attribute analysis to compare the architectural and material culture characteristics of the two areas, I will attempt to demonstrate that differences in site use may be the main contributor to the absence of interaction rather than inter-site violence.

[137] The Face of Foundation: Excavations of the Exterior Plaza Platform Wall at Group B of the Medicinal Trail Hinterland Community
During the 2013 field season, a series of excavations was conducted at Group B of the Medicinal Trail Hinterland Community Archaeological Project (MTHCAP). One of the focus areas for the 2013 season was the exterior plaza platform located to the east of Structure B-1. Prior field season excavations exposed a portion of the north-south orientated wall, as well as an outer corner which redirected a small portion of the wall to the west. An objective of the 2013 excavations was to continue to expose the length of the east-west portion of the platform wall, and to determine its architectural design and integrity. Excavation efforts revealed the continuation of the east-west wall segment, which eventually terminated at an inner corner that redirected the platform wall back to a north-south orientation. The two newly exposed intersecting walls indicate that a possible expansion of the plaza platform may have taken place over multiple construction phases. This hypothesis is based on the comparison of the different construction materials and methods observed at the inner junction of the two platform walls. Other architectural features, such as an upper inset stone alignment and multiple plaster floors, were also observed during the exposure of exterior platform walls.

[172] Stone Cairn Sites of the Northern Appalachian Plateau
Recent surveys for a 120-mile pipeline project in New York and Pennsylvania have identified over 70 separate sites containing one or more cairns of purposefully-stacked field stones. Over 250 individual cairns are represented in this sample from Susquehanna County, Pennsylvania and Broome, Delaware, and Schoharie counties in New York. Stone structures such as these have often been attributed to Euro-American land clearing and property marking activities, but the possibility that at least some of them were built by Native Americans is becoming more accepted by archaeologists. To help explore their origin and function, this poster provides information on setting, arrangement, and construction details on the extensive collection of cairns recently documented, and also reviews comparative data from other Northeastern researchers who have documented similar structures in the Adirondacks, the Catskills, and New England.

Cast, Robert (Caddo Nation of Oklahoma) and Trevor Ware (Caddo Nation of Oklahoma)
The Caddo Nation of Oklahoma, whose homelands spanned the areas of Arkansas, Louisiana, Oklahoma, and Texas, has had a long ongoing relationship with the Arkansas Archaeological Survey (AAS). Because of the presence of the Caddo Indians in southwestern Arkansas as evidenced by archaeological, historical, ethnographic, and oral traditional evidence, together with the amount of archaeological research undertaken within the state over the past 50 years, archaeologists such as Thomas Green understood the importance of consultation on NAGPRA collections held at the AAS and developing research projects of interest to the Caddo people. Dr. Green leaves behind a legacy that promotes and nurtures ongoing communications and relationships between the AAS and all Native American peoples with an interest in the state of Arkansas.

Castaneda, Amanda (Texas State University- San Marcos)
[199] Nose to the Ground Stone: Exploring Bedrock Features in the Lower Pecos Canyonlands
Bedrock features are a common archaeological occurrence in the Lower Pecos Canyonlands. These occur in a wide range of forms, from polished “slicks”, cupules, and small grinding facets to large, deep, well-developed mortar holes. Generally, these features are located in rock shelters, but also occur at open air sites; in both settings while they are sometimes isolated or scattered, most occur in clusters sometimes numbering in the hundreds. These clusters clearly represent major work stations where several different feature forms are present, which could represent different processing methods of targeted resources or perhaps multiple steps in processing a single resource. Even though relatively common, bedrock features, and ground stone artifacts as well, have received very little directed research in the Lower Pecos. Through the use of new technologies such as Structure from Motion photogrammetry and residue analysis, bedrock features are being explored for the research potential they offer in understanding the lifeways of Lower Pecos hunter gatherers. This paper will highlight current research
that is developing a typology of bedrock features across the Lower Pecos landscape, examining
morphology through photogrammetric techniques, and exploring the potential for extracting residues from
mortars in dry rock shelter environments.

[112]  The Central Valley of Puebla and the Formative Period Puebla-Tlaxcala Cultural Complex

The work of García Cook and others beginning more than forty years ago has brought to light the
precocious growth and development of settlement in a large swath of the Puebla-Tlaxcala Basin,
specifically an area encompassing much of the modern State of Tlaxcala and western portion of the
Valley of Puebla. Extensive archaeological work in the Tepeaca area of the central Valley of Puebla
over the past two decades, just outside areas that had been studied previously, has revealed
remarkable similarity in ceramics with the western Puebla-Tlaxcala Basin throughout the Formative
Period. At the same time, there is far less cultural affinity with the Tehuacán Valley to the southeast
and not much further from Tepeaca than is the supposed “heartland” of the Puebla-Tlaxcala culture
region to the northwest. The available evidence suggests that we can safely speak of a cohesive
Puebla-Tlaxcalan culture during the Formative Period. The eastern boundary of this complex is not
yet known; however, we argue that it must now be pushed beyond the central Valley of Puebla.
Focusing more scholarly attention on the identification, characterization, and contextualization of
this archaeological culture is an important future endeavor in Puebla-Tlaxcala archaeology.

[112] Regional Political Strategies during the Classic: A View from Santo Nombre, Puebla

The problem of interregional relations between the southern Puebla region and Teotihuacan in the Early
and Middle Classic periods is addressed based on preliminary data and results of archaeological
excavations carried out at the site of Santo Nombre, Tlacotepec, Puebla. Through a review of the
architecture and artifacts, particularly ceramics and obsidian, the supposed marginal role of regional or
provincial centers such as the one examined here, is reevaluated. The assessment is focused on core –
periphery relations, and the hypothetical marginality of these receiver nodes that have been proposed as
suppliers of strategic resources to the metropolis, through the previously established exchange routes.
Likewise, the possibility is considered that this site was part of a more extended regional and political
system that together developed their own strategies to locally take advantage of the political and
economic expansion of Teotihuacan toward these regions during the Classic period.

[72]  Post-Contact Agriculture and Material Culture Change in Soconusco, Chiapas, Mexico

This paper explores the history of agriculture and its impact on the material culture of rural smallholders
in the Soconusco region of Chiapas, Mexico, though the analysis of land-use patterns and land-cover
change. Following the Spanish invasion, introduction of new materials, technologies, and capital intensive
cash cropping modified the agricultural landscape of the region, but archaeological and historical
evidence suggests that rural smallholders continued to practice traditional agroforestry to meet their
subsistence needs. Moreover, the relative isolation of rural smallholders meant that many new
technologies, tools, roads, and other means of communication, were slow to reach them. However, in the
late 20th and in the 21st centuries, substantial population growth, urbanization and shifting economic
policies based on mechanization, industrial pesticides and monocropping has changed the material
culture and reduced the self-sufficiency of rural smallholders. In Soconusco, previous research on rural
smallholders focused on land-use patterns to document traditional agroforestry systems and to
understand the role of Traditional Ecological Knowledge (TEK) within these systems. To complement
these data, we add multi-temporal and multi-spectral land-cover change analysis in direct tension with
land-use patterns to assess how recent environmental changes are impacting the agricultural and
material practices of rural smallholders in the Soconusco region.

The Nature of Household Burials during the Late Moche Period

Between approximately A.D. 600 and 800, the Late Moche of the North Coast of Peru saw a number of shifts in religious, social, and political behavior before their ultimate collapse by A.D. 800. This study is concerned with shifts in burial patterns during this period. Before this period, "normative" burial patterns followed a predictable organization of burials in cemeteries and in chamber tombs of huacas. The discovery of the urban center of Galindo revealed the first shift from extramural inhumation to 'bench' burials placed inside residential structures. In this study, I look at the emergence of in-house burials within the context of Middle to Late Moche urban sectors, focusing on the site of Galindo with comparative considerations of residential burials found at Huacas de Moche in the Moche Valley and Pacatnamu in the Jequetepeque Valley. The changes in burial practices at these sites reflect shifts of power and beliefs in the context of the final collapse of the Moche. I focus primarily on the implications of a shift from public to private household-based burial rituals, the concurrent occupation of houses during interments, and how changes in burial practices are manifestations of the religious, social, and political unrest during this time.

Islands in the Sea of Grass: Investigating the Environmental History of Everglades Tree Islands

It has been understood that inundation has an adverse effect on archaeological materials. However, archaeological sites in the Everglades system have long been subject to fluctuating water levels. In an attempt to understand the effects of both natural and management caused water level fluctuations the US Army Corps of Engineers, as part of its Everglades Restoration project, is conducting archaeological investigations focusing on understanding the environmental history of Everglades archaeological sites. This poster will provide an overview of the planned investigations.

Hallucinogens and Blood: Grater Bowls from Nixtun Ch’ich’

Archaeologists typically state that grater bowls, molcajetes, were used to process subsistence foods. These vessels are often glossed as chili graters because of the use of the analogy from Aztec, not Maya, codices that show women using molcajetes to grind chilies and beans. In order to test this commonly accepted analogy, I analyzed residues from 14 Postclassic grater bowls excavated from Nixtun Ch’ich’. The vessels were excavated from a ceremonial c-shaped structure (Str. 188), a residence associated with the San Jeronimo mission (Str. ZZ-1), and an oratorio (Str. WW1). The residues from these vessels demonstrate that Postclassic Maya from Nixtun Ch’ich’ were not using grater bowls for processing only subsistence foods, but were preparing hallucinogenic concoctions, sometimes with mammal blood (perhaps human blood). Additionally, the presence of tamarind suggests that this practice continued even after the Spanish came to Nixtun Ch’ich’.

[13] Reconstructing Local Paleoclimate Data with Global and Local Variables: A Re-examination of "Downscaling" with Updated Paleoclimate Models

Climate trends are important in understanding human relationships with their environments. Researchers have long depended on paleoenvironmental proxies, such as ice-cores, marine and lake sediments, and pollen records, to reconstruct broad, low-resolution climate patterns for a particular research area. But these proxies can give ambiguous signals because they can be affected by human activity. During mid-1990s, Reid Bryson developed a method for statistical downscaling of low-resolution, global paleoclimate models to provide modeled weather data tailored to fit the local spatial scales and long temporal sequences of archaeological applications (the latest model allows for 100-year intervals). Despite its utility to archaeological research, Bryson's "Macrophysical Climate Model" approach has been underutilized during the last twenty years. In an effort to refine Bryson's work and make paleoclimate models more accessible to archaeologists at useful spatial and temporal scales, we have incorporated modern, global paleoclimate data from the National Center for Atmospheric Research's Community Climate System Model (CCSM3) into Bryson's downscaling framework. This allows us to combine Bryson's approach with a modern understanding of the dynamics of earth's climate systems. We compare our updated models with proxy data from the GISP2 ice core to evaluate their reliability.

[247] Cremation Funeral Customs among the Classic Period Hohokam of the Tucson Basin Cremation funerary customs are unraveled to acquire a deeper understanding of intersecting identity differences among Classic Period Hohokam (A.D. 1150-1450/1500) of the Tucson Basin. This is done by analyzing the mortuary treatment of 281 individuals using two primary datasets: (1) biological profile of the skeletal remains and (2) posthumous treatment of the body inferred from the analysis of the remains and archaeological contexts. Preliminary results indicate the existence of social differences in funerals related to age-at-death and sex identity intersections. However, funerary customs also were less elaborate and more "private" than in the preceding Preclassic Period (A.D. 700-1150). These findings suggest that a general decrease in remembrance networks occurred through time. Social trends observed in Classic Period Hohokam mortuary customs in the Tucson Basin parallel broader sociopolitical changes previously proposed for the Classic Period Hohokam, including increased social differentiation and complexity.

[104] Residential Occupation in the Capital of the Sican State, Peru The capital of the Sican state (900–1100 A.D.) located in the middle La Leche valley, North Coast of Peru, has been interpreted to have been a sacred religious precinct with six major multi-level platform mounds, which are believed to symbolize the six elite lineages that competed for the political leadership. While an elite cemetery and a group of attached craft workshops associated with some of these mounds have been documented, residences of the population that supported the capital has not been properly defined. During the summer of 2013, a preliminary reconnaissance of the Sican capital and its surrounding areas to the east and west within the mid-valley was conducted to identify residential areas and record their surface material composition and density so as to gain an insight on the intensity and scale of occupation during the political hegemony of the Sican State. This poster presents results of the preliminary work that complement the existing knowledge and understanding of the elite and ritual activities of the Sicán capital.

[121] Material Culture in Coastal Chullpas from Tacahuay Tambo / Pueblo In 2010, during excavations conducted at the coastal site of Tacahuay in the Colesuyo region of Southern
Peru, a team of archaeologists found exceptional funerary contexts. While looking for qolqas (Inca storage constructions), the team unintentionally crossed into two funerary structures known in the Andean region as chullpas (houses of the dead). These structures were buried under deep aeolian deposition and were not recognized on the surface, remaining intact for more than 500 years. Here, I describe the importance of these findings, propose future investigations of chullpas in the Colesuyo and offer a preliminary bioanthropological analysis. I also present analyses of multiple types of Inca material culture found inside these chullpas, and discuss their social history.

Chacon, Richard [288] Fighting or Feasting? Pathways to Social Inequality in Egalitarian Amazonia and New Guinea
This research documents two pathways by which individuals acquire elevated positions of prestige in their respective tribal societies. The first route involves participation in warfare as a means for obtaining high social standing among Amazonian Indians. Individuals who exhibit courage in battle are rewarded with prestige by fellow villagers. The second approach involves participation in economic activities for obtaining high social standing among the Western Dani of New Guinea. Successful sponsors of large pig feasts are rewarded with prestige by their fellow villagers. These two pathways are investigated by way of case studies marking the advent of social inequality in disparate egalitarian settings. This research will also apply experimentally tested sociological theory to understand how the presence of incipient social inequality may help foster collective action.

Chambers-Koenig, Emma (University of Alabama)
Ritual Deposits and Abandonment Processes at Aguacate Uno, Belize
Recently there has been a growing interest in the study of site-specific abandonment processes that occurred in the Maya Lowlands during the Late to Terminal Classic periods. These studies recognize the need for the analysis of artifact assemblages to understand the multifaceted processes of abandonment. Excavations at the minor center of Aguacate Uno uncovered four terminal deposits in the two major civic structures. On the northern structure deposits were found overlaying the entrance staircase and within a room on the medial terrace. On the southern structure deposits were found on the summit and within a room attached to the base of the building. Three of these assemblages resemble those associated with abandonment processes found across the Maya Lowlands: termination rituals, structure decommissioning, and occupational trash. The fourth deposit is unlike the other three and may suggest revisitation to the site after it was abandoned. By sampling and comparing contexts and artifacts from the four deposits, a more comprehensive understanding of Aguacate Uno’s abandonment timeline and processes can be reached. This study has the potential to influence how archaeologists study abandonment processes, but also explores questions about what happens to a site, as well as its previous inhabitants, after abandonment.

Imperialism and the Urban Landscape in Ptolemaic Egypt
The purpose of this research is to examine the ancient urban landscape to evaluate the character and degree of colonialism, or more specifically imperialism, in Ptolemaic Egypt. Through a qualitative study of three settlements, Alexandria, Naukratis, and Thmouis, changes in the urban landscape and the effects of imperialism can be determined. Comparisons can be made between a number of urban features found at each settlement, such as neighborhoods, buildings, roads, fortifications, harbors, palaces, temples, commercial areas, and industrial spaces. From this, patterns can be distinguished in settlement design, cultural divisions, and colonial influence. Theories of colonialism and imperialism aid in understanding
relations of dominance in a colonial setting and distinguish urban features that were constructed as part of a colonial agenda. This research leads into the study of the significance of establishing new colonies where functioning settlements already exist in a colonized land.

[334] Yours or Mine? Bone Gaming Pieces from the American Southwest
Enigmatic bone artifacts referred to as “gaming pieces” are found throughout the American Southwest although they appear to have their apex during the Basketmaker II period. The pieces are small, thin, and display a variety of shapes, with one side usually incised or scored. Most often they are found as isolated occurrences; however, they have been documented in sets or groups suggesting they functioned in some type of recreational capacity. Bone gaming pieces (dice, disks, or counters) are referenced in Stewart Culin’s “Games of the North American Indians” where he suggests a long antiquity for games of chance using similar items while citing ethnographic analogies with the Zuni and Hopi tribes. In this paper I discuss an assemblage of over 150 gaming pieces derived from Basketmaker II and Pueblo I sites near Durango, Colorado, and compare them through time and space to similar artifacts from other sites in the Southwest. I hypothesize that gaming pieces were an early iteration of a communal game similar to Pogs, where individual pieces, and perhaps their creators, could be identified by shapes and etchings.

Charles, Douglas (Wesleyan University)
[340] Middle Woodland Things and Hopewellian Things
Middle Woodland period things share several characteristics: (1) they are of local origin; (2) they were generally abandoned (e.g., refuse) or dismantled (e.g., structures); and (3) they were acquired either because of their specific technological properties (e.g., chert and clay) or incidentally (i.e., contained in plants and animals), or they are simply taphonomic byproducts (e.g., post molds). Conversely, many of the things we attribute to the Hopewell phenomenon share different characteristics: (1) they (or the raw materials) were transported considerable distances; (2) they were often intentionally deposited (sensu Schiffer 1972, 1987) in grave caches or in a patterned manner; and (3) they were seemingly chosen for visibility or durability, or for symbolic reasons. These differences result not just from the agentic acts of the people, but also from the agency of the things. This paper will explore the agency of things and the extent to which such a perspective enhances our understanding the Middle Woodland period and the nature of Hopewell.

[124] Pastoral Land-Use of the Indus Civilization in Gujarat: New Findings from Biogenic Isotopes and Faunal Analyses
The Indus Civilization (2600-1900 B.C.) in Gujarat, India is characterized by a network of small yet monumentally walled settlements, many of which functioned as centers for the manufacture of highly valued Indus ornaments from locally available raw materials that were traded to distant Indus cities. Investigation of the ways in which the residents of these settlements produced or obtained their daily subsistence needs is fundamental to more complete interpretations of Indus political economy and social dynamics in this important borderland region. As a direct interface between human societies and the physical landscape, archaeological faunal remains have the potential to provide powerful insights into these issues. The bones and teeth of domestic animals preserve a record not only of human production and consumption practices but also the geographic and environmental contexts in which they were raised. Here, faunal analyses are combined with a consideration of variation in biogenic isotopes in the tooth enamel of domestic animals from Indus archaeological sites in the region. Our findings reveal important new insights regarding pastoral land-use in and around these settlements, laying an empirical foundation for novel understandings of South Asia’s first urban society.

The Myths of a History: Wak’as, Temporality, and Performative Historicities in Huarochirí, Peru (ca. A.D. 1500-1700)

The central Andean region of Huarochirí produced a unique Quechua manuscript which has served as an invaluable reference for archaeologists and historians. In this paper, data from the first systematic archaeology carried out in the epicenter of the manuscript’s composition will be presented to reveal insights into the operation of mythical narrative, ritual, material culture, and landscape in the performance and construction of new temporalities, collective identities, and socio-political relations during two successive processes of colonization (Inka and Spanish) during the late prehispanic and early colonial periods. Considered together, the archaeological and textual data not only suggest revision of accepted historical reconstructions of Huarochirí’s past, but also allow for revelatory ethnohistorical interpretations which require rethinking our notions of temporality and historicity in the Andes. The presentation makes an argument for the temporally and socially generative power of superhuman material entities known as wak’as, and demonstrates how particular culturally and historically nuanced understandings of time can inform the design of archaeological research questions in the late prehispanic and early Spanish colonial Andes.

Large-Scale Maya Regional Settlement and Inter-Site Analysis: Results from the 2013 West-Central Belize LiDAR Survey

During April and May 2013, a total of 1050 square kilometers of LiDAR was flown by NCALM for a consortium of archaeologists working in west-central Belize, making this the largest surveyed area within the Maya lowlands. Encompassing the Belize Valley and the Vaca Plateau, west-central Belize is one of the most actively researched parts of the Maya lowlands; archaeological projects have focused on at least 18 different sites within this region. Thus, a large body of archaeological research provides both the temporal and spatial parameters for the wide variety of ancient Maya centers that once occupied this area; importantly, these data can be used to help interpret the collected LiDAR data. The goal of the 2013 LiDAR campaign was to gain information on the distribution of ancient Maya settlement and sites on the landscape and particularly to determine how the landscape was used between known centers. The data that were acquired through the 2013 LiDAR campaign have significance for interpreting both the composition and limits of ancient Maya political units. This paper presents the initial results of these new data and suggests a developmental model for ancient Maya polities.

Water Capture and Agricultural Terracing at Caracol, Belize as Revealed through the 2009 LiDAR Campaign

In April 2009 a LiDAR survey flown by NCALM recorded 200 square kilometers of terrain that comprised the Maya site of Caracol, Belize. The data that were acquired revealed a densely settled site spread throughout this area with residential groups situated within an extremely manipulated landscape. The LiDAR data helped to demonstrate the full extent of the extensive Maya urban settlement that existed in this portion of the Vaca plateau. Settlement was also interspersed with agricultural terraces used both to grow food and to direct the flow of water over the terrain. The ancient Maya controlled soil erosion through the use of carefully constructed terracing that both retained water and managed its gravitational flow through the topography. Constructed reservoirs, usually in close proximity to residential groups, were also widely distributed throughout the landscape. These data show that water management practices at Caracol were shared by the bulk of the site’s population and did not fall solely within the purview of the ancient Maya elite—contradicting some archaeological reconstructions for their society that suggest that royal power was directly tied to the control of this important resource.

Chatelain, David (Tulane University)

Water, Labor, and Control at the Minor Center of La Cariba, Guatemala

The site of La Cariba is situated in the northwest Petén region of Guatemala, in the periphery of the larger site of La Corona. In what is increasingly being revealed as an area with strong political connections to the Kaanal dynasty during much of the Classic period, the minor center of La Cariba may shed more light
on political organization at the local level. Based on topographic mapping data collected during the 2012 field season, GIS-based analyses are used to construct hydrological models of water management features at the site and to estimate construction volumes of structures in the site core. These lines of evidence can provide insight on the ability of the rural elite to organize labor and begin to answer broader questions of social and political organization in the peripheral areas of Maya polities.

Establishing the Chronology of an Association between a Human and Pleistocene Megafauna in Hoyo Negro, a Submerged Cave on the Yucatan Peninsula

Cave Divers mapping the submerged caves of the Yucatan Peninsula over the past 20 years have often discovered the remains of humans and extinct megafauna that entered at a time of lowered sea level. Dating these finds by radiocarbon dating of collagen has proven impossible due to the near-complete loss of bone proteins in the warm tropical waters. It has thus proven essential to innovate alternative approaches. In Hoyo Negro, Quintana Roo, Mexico, remains of a human, gomphotheres, two giant ground sloths, possible Florida cave bears, and sabertooths have been found directly associated by depth and/or position, all in unburied context. Remains of the human and one gomphothere are commingled. To determine absolute and relative ages of these species we turned to a combination of direct dating by radiocarbon analysis of tooth enamel, and indirect dating by uranium/thorium analysis of speleothems and reconstructing postglacial sea-level rise within the cave through the ages of bat guano and calcite raft cones. Analytical work was completed by the University of New Mexico, Pennsylvania State, Northwestern, and McMaster Universities, Stafford Laboratories, and DirectAMS. First applied to the human and gomphothere, this approach has shown that association does not necessarily equal contemporaneity.

Chávez Balderas, Ximena (Proyecto Templo Mayor)

Images of Death: Symbolism, Use and Reuse of Human Skulls at the Templo Mayor of Tenochtitlan

From 1948 to 2012, 108 decapitated victims were recovered from the excavations of the Templo Mayor of Tenochtitlan. The biological profile of the individuals is diverse: adult females, males, subadults and children were placed in the offerings. Independent of this diversity, human skulls were buried as severed heads and as god effigies. Severed heads were associated with the consecration of the temples, a widespread practice in Mesoamerica. Reused tzompantli skulls, skulls with basal perforation, and the so-called skull masks were deposited in the offerings as effigies of deities related to the earth and death, particularly of the god of the Underworld, Mictlantecuhtli. Numerous osteological indicators found in these skulls support the idea that most of them were not manufactured ex-professo for this purpose. If these individuals were not decapitated for manufacturing these effigies, what was their original function? Four sources of information can give us potential answers to this question: codices, written documents, other archaeological skulls and Aztec sculpture. In this paper I will explore the symbolism and the complex chain of use and reuse of these important components of the cosmograms.

Levallois without Levallois: Late Lower Paleolithic Flake Industries in the Levant

Confusion between the typological and technological definition of Levallois is an impediment to understanding the emergence of this method. In the Late Lower Paleolithic of the Levant a low percentage of typologically Levallois flakes are found in industries that do not show evidence of the Levallois method as defined technologically. These industries thus represent a challenge to archaeologists. If looked at typologically these assemblages would suggest the gradual development of Levallois while from a technological perspective such a gradualistic perspective makes little sense. In this paper I will go back to the industry from the site of Holon, which has been dated by OSL and ESR to OIS 7. At this site I suggest that the flake industry is best understood as the product of the trifacial method. The implications of this interpretation for the understanding emergence of the Levallois provide an opportunity to consider the relationship between the late Lower Paleolithic and the Middle Paleolithic in the Levant.

[20] The Chemistry of Mobility: Preliminary Results, Potentials, and Challenges of Isotope Analysis in the Tsaghkahovit Plain, Armenia  

In the last decade, Eurasian archaeologists have focused on the numerous ways in which people’s lives and social landscapes are shaped both by movement and by human-animal relationships in a broad spectrum of pastoralist societies. Isotope analysis has the potential to refine these understandings by tying movement to specific geographical locations, diet regimes, seasonality, and long-term climate change. In the broader field, isotope research has burgeoned in the last ten years, focusing particularly on questions of migration, colonialism, and residential movement within states and empires. In contrast, the use of isotope analyses in Eurasia offers the opportunity to investigate different questions and generate innovative models and new ways of understanding mobility in prehistoric societies, even as it poses specific challenges. The salience of human-animal relations in Eurasian pastoralist societies demands the generation of new approaches to constructing research projects and interpreting isotope data that better integrate data sets. We present preliminary results on from isotope analysis of assemblages from the Bronze Age Tsaghkahovit Plain, Armenia. Bringing together data on human and animal remains, we outline the first steps towards building a comprehensive program of isotope analysis from the ground up and discuss the potentials and challenges for future research.

[188] Foundation Deposits in the Eighteenth Century Caribbean  

Work on two separate eighteenth-century sites in the rural British Virgin Islands has uncovered unusual deposits at the bases of post-holes in the foundations of plantation houses. The homes are of a similar period, but otherwise have no direct relation. Not likely to be structural and clearly intentional, there is a possibility that these deposits were made with religious and/or magical intentions. This possibility is made more unusual in light of the fact that one of these sites certainly is—and the other may be—associated with a community of the Religious Society of Friends (“Quakers”) known in part for their rejection of the “superstitions” of mainstream worship such as sanctified spaces, ritual, and ritual objects.

[179] The Curious Case of Charlie Chaplin Figurines: Ritual Meaning and Context of Small Anthropomorphic Maya Carvings  

Small anthropomorphic figurines, known as “Charlie Chaplins,” have been recovered from ritual cache contexts at various Lowland Maya sites that date to the Late Preclassic and Early Classic periods. The curious name is a label first designated by J. Eric S. Thompson in the 1930s. The occurrence of these Charlie Chaplin figurines is widespread throughout the Maya subarea and may even be a shared, pan-Mesoamerican ritual item. Similar figurines, for example, have been recovered from Teotihuacan, while other figurines, known as camahuiles in the Highlands of Guatemala, penates at Monte Alban, and mezcala in the Guerrero subarea of Mexico, have been identified. These humanoid carvings often portray features such as eyes, mouth, arms, hands, legs and feet, while others are more abstract, with simple incised lines representing heads, arms and legs. The so-called Charlies of the Maya subarea are often carved from materials such as marine shell, slate, jadeite and even obsidian. This paper will examine this class of Maya artifact, and present information on contexts and possible ritual meanings based on recently excavated Charlie Chaplin figurines from the North Group of Pacbitun (Belize). Similar artifacts from other Maya/Mesoamerican sites will be used in a comparative analysis.

[162] One Thousand Years of the Royal and Noble Hunt in the Aegean  

This paper uses archaeological data, artistic representations, and literary evidence to trace various forms of symbolically-charged hunting activities in the Aegean over the course of more than 1000 years, from the Late Bronze Age world of Minoan and Mycenaean princes and kings to that of Alexander the Great and his Hellenistic successors. Bronze Age kings and their entourage surrounded themselves with imagery of the hunt and the display of weaponry, grave stelai, wallpaintings, and sealstones focusing
especially on dangerous animals such as wild boars and lions. The latter draws on Near Eastern iconography, symbolically linking royal power and control with the qualities of the lion as an apex predator. Homer too reflects these ideas. In the non-monarchical societies of Crete several centuries later, hunting expeditions seem to have played an important role in rites of passage and enculturation for young elite males. The westward expansion of the Persian Empire, however, introduced to Anatolia and Mediterranean Europe the notion of hunting in designated royal parks (paradeisoi). After Alexander destroyed this empire, he adopted both the practice and the representation of the royal hunt in a wide variety of media (mosaic floors, painted tombs, stone sarcophagi, etc.) as emblematic of supreme power.

Chesson, Meredith (University of Notre Dame)
[145] Slow Urbanism: The Other Urban Revolution in the Early Bronze Age Southern Levant
Recent reevaluations of traditional models of urbanism in Old and New World contexts have transformed how we approach and understand the earliest urban societies, decoupling the notion of urbanism and cities as requirements for political complexity in typologically-driven studies of ancient states. This paper describes a case study of small-scale urbanism: often characterized as a marginal backwater in the grand narrative of emerging urbanism in the ancient Near East, the southern Levantine peoples who lived in modern day Jordan, Israel, Palestine, southern Syria, and Lebanon developed their own version of urbanism in the Early Bronze Age I-III (EBA, c. 3500-2300 B.C.E.). This brand of urbanism, what I term Slow Urbanism, emerged from localized histories and relationships, lacking a widespread presence of elites, powerful civic and ritual institutions, international exchange networks, prestige goods, writing systems, pronounced sociopolitical complexity, or large cities. Using mortuary evidence from Bab adh-Dhra’ (Jordan) and Jericho/Tall as-Sultan (Palestine), I track the tempos along the pathways to a Slow Urban society, examining how EBA people invented small-scale cities in which the very nature of urbanism was necessarily diverse, localized, and lacking in pronounced social and political differentiation.

Cheval, Carole (Chercheur Associé ArScAn UMR7041)
[22] Identifying Treatment of Fibers by Analysis of Bone and Wood Tools used in Textile Production: the Neolithic Sword Beater
Sword beaters, with blades made of bone and wood, were important weaving tools in Neolithic Europe. Following the implementation of an experimental protocol concerning these enigmatic tools, which are rarely recognized archaeologically, I have been able to establish diagnostic criteria for identifying possible sword beaters at prehistoric archaeological sites. These tools are found at several sites dating between 4550 B.P. and 2850 B.P. in southern France and Italy. If our experimental reference work is extended, we may be able to determine which fibers were used for textile production during the Neolithic. Such findings could reveal a virtually unknown practice in prehistoric economy, and they could shed light upon the procurement and use of plant and animal resources by populations living during early stages of plant and animal domestication.

Chiarulli, Beverly (Indiana University of Pennsylvania)
[292] Finding Economies of Scale from Household to Regional Patterns of Lithic Distribution in Northern Belize
Discussions of trade in the Maya lowlands have frequently focused on long distance trade and its contribution to the development of Maya hierarchical organization. Less attention has been paid to the development of intra-regional or intra-site distribution networks. There has been an assumption that both exotic and regionally produced goods were distributed to local markets and networks in that region through the same although undefined processes. In fact, there may be different networks for different goods that may reflect the needs of the consumers as well as those of the producers. Northern Belize is an ideal region for an investigation of the different networks for the distribution of lithic artifacts because of the number of sites that have been investigated. The region contains the only large scale lithic production site in the Maya area and is also connected to long distance trade networks in obsidian. This paper examines the multiple distribution networks in northern Belize through an analysis of stone tools and their manufacturing debris that allow us to trace the movement of raw materials and finished products into and throughout the region and individual communities.

**Plazas: Contexts of Performance and Sociopolitical Integration in Coastal Ancash during the Formative Period**

In this paper, we evaluate plaza performances and sociopolitical integration in coastal Ancash during the Formative Period. Recent field research in the region suggests the development of polities and communities of different levels of integration based on settlement patterns and the distribution of ceramic styles. These developments coincide with the abandonment of Chavín and Cupisnique-related religious centers in the region between 800 and 500 B.C.E. We explore the shift in patterns of ritual practices and built ritual settings after the demise of large regional centers in coastal Ancash. The Late Formative marked the emergence of a multitude of community that seems to vary in scale, complexity and modes of social integration. Through a comparison of plaza settings and associated material assemblages, we delineate different nodes of sociopolitical integrations. Results suggest that the demise of Middle Formative regional ceremonial centers and the development of Late Formative settlements marked, at least in some areas of coastal Ancash, a decentralization of ritual practices. Rather than being limited to large-scale gatherings at regional centers, the fragmentation of the ritual landscape—and especially the integration of plaza settings within exclusive residential environments—point toward the appropriation of ritual practices by multiple competing groups.

**Evaluating the Drivers and Triggers of Ecosystem Dynamics in Pre-Contact New England**

The interpretation that Native American land-use played an increasing role in landscape dynamics through the Holocene is widespread. Newly proposed is the interpretation that major cultural changes in the northeast coincided with significant climatic and vegetation changes. However, there are no robust analyses of regional archaeological and paleoecological data to test either assertion. This paper describes the archaeological component of a larger NSF-funded research project intended to analyze the drivers and responses to ecosystem dynamics in New England. The archaeological effort aims to understand the dialectical relationships between human activity (fire, land clearance, horticulture) and vegetation dynamics. Some of the specific alternative hypotheses examined in this research are: (1) are changes in vegetation the result of cultural or climatic shifts? (2) were people passively responding to environmental change, contributing minimal ecological impact themselves? or (3) do vegetational histories demonstrate the clear influence of human agency? We present preliminary results from the analysis of statewide site archaeological data and more detailed analysis of data from three subregions in Massachusetts.

**Cosmogony and Human Sacrifice at Tikal, Guatemala: Interdisciplinary Approaches to the Primary Cremated Multiple of PP7TT-01**

Mesoamericanist research on human sacrifice and fire ritual bypasses some of the material constraints of archaeology, taphonomy, and osteology by bringing into play the vast ethnohistorical corpus of written texts and artistic representations. In this paper, we apply an integrated approach to the reconstruction and interpretation of a partially cremated primary context at the Lowland Maya city of Tikal, deposited sometime during the 5th century A.D. To this end, we analyze the remains of two males who were put to death, cremated and buried on the spot on the axis of a public E-Group complex with strong solar connotations. Detailed taphonomic reconstruction reveals details about the form of death and combustion of the two bodies, while isotopic studies hint at the individuals’ probable geographic origin and residence. These data are relevant considering the event’s historic coincidence with a critical period in Tikal’s history, marked by intensified cultural and political interaction with the highland Mexican city of Teotihuacan, materialized in this context by the presence of imported green obsidian spear points. When considered jointly with ancient Mesoamerican mythology and ritual, this unique context appears to materialize a sacrificial reenactment of the mythological birth of the sun and the moon.

Chirinos Ogata, Patricia (University of California, Santa Barbara)
Power Relations between Wari and Cajamarca at the Empire Frontier: Preliminary Excavation Results from the Site of Yamobamba, Namora Valley, Peru

When the Wari Empire reached the Cajamarca region in northern Peru during the Middle Horizon (A.D. 700-1000), extensive centers were built, small local settlements were abandoned, and the prestigious Cajamarca pottery began to appear in elite contexts in several Wari sites. Within this context, multiple scenarios of political negotiation most certainly defined the interaction between the powerful local polity and the expansive empire coming from the south. Recent research at Yamobamba, a monumental site in the Namora valley in Cajamarca, revealed a typical Wari architectural layout, with squared patios surrounded by tall, narrow corridors and galleries. However, small platform mounds and checkpoints indicate that formal variation, corresponding to functional differences, was established among the patio-groups. This poster summarizes the finds from the first season of excavations at Yamobamba. While the Wari secular elements are predominant at the site, functional diversity is suggested. In addition, ceramic vessels found at Yamobamba correspond to a local occupation during the Middle Horizon, but no evidence of Wari ceramics has been recovered. Together, the finds suggest that the occupation at Yamobamba must be seen as the outcome of intricate and fluctuating power relations rather than direct control of Wari over Cajamarca.

Taphonomy of a Cutmark: Post-depositional Changes to Cutmark Morphology in a Simulated Fluvial Environment

Researchers have long relied on careful actualistic studies of bone surface modifications to distinguish cutmarks from non-anthropogenic surface modifications, especially in the context of early hominin behavior. However, few actualistic studies examine how post-depositional processes alter the microscope features used to identify cutmarks from other taphonomic agents. We simulated the erosional processes of a streamside depositional environment by securing stone tool butchered elk bones in a flume at the Saint Anthony Falls Laboratory, MN. Cutmarks were described and examined with a stereomicroscope and an ESEM at regular intervals. Our results show that even if there is no noticeable rounding present on a bone, cutmark morphology can be altered quickly. During out study we observed the following: (1) V-shaped cutmarks became wider, deeper, and asymmetrical; (2) smaller, shallower cutmarks disappeared completely; (3) features such as shoulder effect and flaking were frequently lost. Furthermore our findings suggest that grain size distributions may predict how cutmark morphology and features are altered. These results highlight the importance of the sedimentological context for the interpretation of all zooarchaeological butchery sites and the need for additional studies on the preservation of surface modifications.

New Discovery for Sourcing New Caledonian Lapita Pottery Based on Petrographic Studies of 10 Lapita Sites

After comparing 118 thin section samples collected from 10 Lapita sites, we have established a more systematic way of describing and sourcing New Caledonian Lapita pottery based on petrographic analysis, and have identified three new possible sources for manufacturing Lapita pots. In this paper, we will describe what type of index minerals that we used to find out the possible source of a given ceramic vessel, and what this refined classification system may enable us to do in the future study of Lapita pottery in this region.

The Identification of Archaeological Social Boundaries in West Michigan and Northwest Indiana: An Integrative Approach

This research examines approximately 500 Middle Woodland (ca. 150 B.C.–A.D. 300) pottery samples from west Michigan and northwest Indiana to define the boundaries of different types of communities on multiple spatial scales. It fuses stylistic and morphological analyses with compositional (i.e., ceramic petrography) analyses and employs a bottom-up approach by initially identifying communities on the intraregional spatial scale before examining their participation in regional and interregional interaction networks. The results have provided insight into the complex and dynamic types of cultural interactions operating within the study region and the distinct behavioral patterns unique to each individual community, and have contributed to a more complete understanding of the spread of the Havana-Hopewellian phenomenon outside of the “cores areas” of Illinois and Ohio. In general, this research has
advanced our knowledge regarding identity formation and modification that may accompany the adoption of a foreign belief system.

Chiykowski, Tanya (SUNY Binghamton)

[C200] Ceramic Production and Trade at Cerro de Trincheras, Sonora, Mexico

The late prehistoric period of Northwest Mexico and southwest America was characterized by the long distance movement of people and pots. This paper addresses the introduction of new ceramic production methods to the Altar and Middle Magdalena river valleys in Sonora Mexico. Sand, used to temper domestic ceramic wares, has been collected from the two sub-areas to study the introduction of paddle-and-anvil ceramics to the site of Cerro de Trincheras in the Magdalena Valley. After A.D. 1200, migration of a Hohokam-like population into the Altar valley introduced a new form of ceramic production, paddle-and-anvil, completely replacing earlier production techniques. In the Middle Magdalena the density and size of Trincheras Culture sites increased dramatically. While potters continued to produce ceramics using the traditional coil-and-scrape method, a third of the sherds at Cerro de Trincheras were paddle-and-anvil. A small minority were a hybrid of the two production methods, suggesting contact and diffusion of technological style between the two cultures. Geological sourcing will address whether these ceramics were part of interregional exchange across cultural barriers or the result of mixing of migrant communities at the site of Cerro de Trincheras.

[13] Photogrammetry Applications in Feature and Site Documentation: Case Studies in Southeastern Alaska and Northwestern Nebraska

The discovery and documentation of archaeological features represents an important yet challenging aspect of pedestrian survey. The information potential of these sites is great, but little is done at the point of initial discovery in relation to preservation and documentation. Decisions about future work, monitoring and relocation are then made at a later date. Here we report on a pilot study to use low-cost, off-the-shelf photogrammetry for the documentation of rock cairn features in Tongass National Forest and pit hearth features in contexts throughout the Oglala National Grasslands. The ease of use, rapid data acquisition, and cost effectiveness of this technique demonstrate its promise as an important tool for archaeological survey. The fine resolution models created for individual features can supplement in-field measurements and provide a baseline for assessing rates of degradation. The models may also be used as a means of community outreach as a medium for linking archaeological features to modern communities.

Chouest, Matthew (Louisiana State University)

[221] Caves and Class: Excavations at the Lang-Jourdan House in Mandeville, Louisiana

The Lang-Jourdan House (16ST248) in Mandeville, Louisiana was constructed in the mid-1850s for a wealthy tobacco merchant named Jean-Baptiste Lang who used it as a summer home until his death in 1861. The house had been continuously occupied until it was seriously damaged by Hurricane Katrina in 2005; it has since been relocated and currently being converted into a museum as one of the few remaining examples in Mandeville of an original Anglo-Creole cottage. The most significant feature of the house is its "cave," a semi-subterranean structure that was used as a wine cellar which was excavated in January 2013. There are few extant examples of caves in Lower Louisiana due to the difficulty of maintaining such a structure with the high water table. Lang could clearly afford to have and maintain such an extravagant amenity, and as such, the cave can be linked to elite Creole society and class in antebellum Louisiana.

Chovanec, Zuzana (University at Albany) and Sean Rafferty (University at Albany)

[301] Examining the Prehistoric Use of Aromatic Plants: Procedures, Considerations, and Archaeological Applications

This poster presents the theoretical bases, methodology, and the research results of two case studies for the identification of aromatic plants in organic residues preserved in archaeological contexts. Gas Chromatography-Mass Spectrometry (GC-MS) was utilized to characterize a series of aromatic plants that are indigenous to the Eastern Mediterranean island of Cyprus, the essential oil profiles of which were later used to identify aromatic products in ceramic vessels that span the Bronze Age on Cyprus. Methodological procedures and case studies are presented. Future directions for aromatic plant research are also addressed.

Christie, Jessica (East Carolina University)
[183] Inka Stone Ideology in Peripheral Regions of the Empire
Numerous archaeological projects have investigated Inka administration in the outlying provinces (synthesis by Malpass and Alconini 2010). I add the perspective of stone wak’as and refer to selected case studies of where and how the Inka materialized their presence by manipulating local empowered stone formations. I have argued elsewhere that Pachakuti Inka Yupanki devised a strategy of stone ideology which marked stone wak’as in the heartland as Inka by means of a geometric carving style. Stone ideology and its visual vocabulary were exported along extended zeq’e lines, roads, and into outlying centers as the empire extended. I will focus upon presence or absence of stone ideology in specific regions and what these data might reflect about levels of Inka control. Sites to be discussed are the large carved outcrops at Ingapirca (N) and Samaipata (S), as well as the unmodified boulder at Espiritu Pampa (E). Examples of local wak’a capture by containing bedrock outcrops with Inka-style walls can be registered at Los Paredones on the south coast, Sondor in the Andahuaylas region, and at Watoq’to near Paucartambo. The anomaly is the north coast where specific Inka stone wak’as appear to be absent.

[334] Recognition of Paleoindian Mobiliary Art: Examples and Experiments from the Gault Site, Bell County, Texas
Incised stones from the Gault Site, with deposits ranging from Pre-Clovis to Late Archaic, have been recognized as some of the earliest provenienced art in the Americas. Recognition of these artifacts, whether in the field or in the lab, can be difficult; in fact, surveys of existing collections from a variety of sites have identified incised stones that were not previously described as mobiliary art. The Gault School of Archaeological Research has developed both field and lab protocols to maximize the potential of saving and identifying these artifacts, and reproductive experiments are refining our ability to recognize and interpret incised stones. Paleoindian mobiliary art may not be as rare as has been assumed.

[186] Isotopic Indicators of Terrestrial Ecosystem Change in the Turkana Basin: Implications for the Holocene Archaeological Record
Cultural and technological changes visible in the archaeological record are often linked to changes in the terrestrial environment. Variation in the strength of the eastern African monsoon, forced by orbital geometry, was a major driver of Holocene environmental change. The appearance of herding in the Turkana Basin ca. 4000 14C B.P./4800-4000 cal B.P. may coincide with weakening monsoons and a regional shift towards a more arid climate. However, little is known about the local ecological contexts in which changes in economy, culture, and social organization may have played out. Stable isotope analysis of prehistoric fauna reveals the impact of changing insolation during the Holocene (11.5 Kya - present) on climate, rainfall seasonality and terrestrial ecology within Kenya’s Turkana Basin. Tooth enamel from localities spanning the early Holocene “strong monsoon” period to the later Holocene “weak monsoon” period were sampled for stable carbon and oxygen isotopes. Initial results indicate a distinct humid-to-arid climatic change, in accordance with insolation forcing and proxies from other parts of eastern Africa, as well as diet change to an increasing fraction C3-dominant biomass, which may indicate changes in floral composition. Economic changes from early Holocene fishing to middle Holocene herding appear to articulate with distinct changes in local terrestrial ecosystems.

Chuipka, Jason (PaleoWest Archaeology)
[18] Looking Beyond the APE: Landscape Level Research in the San Juan Basin and the Navajo-Gallup Water Supply Project
Most archaeological salvage projects have excavated everything in harm’s way to compensate for adverse effects to historic properties. However, there is a need to look beyond the right-of-way or area of
potential effect. The San Juan Basin of northern New Mexico is one of the most archaeologically rich areas in the Southwest and has witnessed many archaeological salvage projects in the past 30 years. Contextualizing finds from preliminary testing and more complete site excavations within a landscape-level interpretive framework is the primary aim of the Navajo-Gallup Water Supply Project research. More specifically, the project is considering what excavations would generate data to add to what we already know about this region. This paper outlines the research themes that structure the investigations and describes strategies being implemented so that this project will make substantial contributions to archaeological studies of the northern Southwest.

Church, Warren (Columbus State University, GA)

[281] Prehispanic Travel and Transport Assemblages from Peru's Northeastern Tropical Montane Forest

"Inter-societal interaction" and "mobility" are growing theoretical concerns in Andean archaeology. While identification of production centers and modes of economic distribution are important at the theoretical level, it behooves us to remember that the tasks of travel and transport were conducted by people who usually carried items for personal use and/or exchange, perhaps in durable containers, as they labored up and down mountain trails. Manachaqui Cave is a small rockshelter with stratified deposits situated beside a prehispanic road connecting the northeastern Andean highlands and known monumental settlements deep in the cloudforest. Although the site's functions clearly changed during its 10,000 year use, a combination of contemporary ethnographic observations, ethnohistorical information, and functional analyses of artifacts (especially ceramics) and organic remains, attests to Manachaqui's function as a trail-side shelter or "wayside station" during various periods. This paper presents evidence for the rock shelter's changing functions, but focuses on the archaeological identification of "travel assemblages," and how their compositions likely responded to technological innovations (i.e., llama caravan transport) and socio-political developments in northern Peru.

Church, Robert (C&C Technologies, Inc.)

[307] Deep-Water Shipwreck Site Distribution: The Equation of Site Formation

Deep-water shipwrecks and associated debris often sit on the bottom with relatively little disturbance except for the natural bio-chemical deterioration. The distribution of shipwreck material can often be calculated mathematically as a function of heading, speed, time, and water depth. In 2007, archaeologists with C & C Technologies published a debris distribution model from data collected during a Deep Shipwreck Project in the Gulf of Mexico for the former U.S. Minerals Management Service. The researchers have continued to refine the formula with additional shipwreck information. Using additional standard equations in combination with the distribution model provided a greater understanding of the distribution of material and initial site formation. The information learned was then applied to deep-water sites such as the passenger freighter Robert E. Lee and German U-boat, U-166 (both 1,400 meters below sea level) in the Gulf of Mexico to help draw a clearer picture of the initial site formation process for other deep-water sites and the wrecking events themselves.

Churchill, Steven (Duke University), Christopher Walker (Duke University) and Adam Schwartz (Duke University)

[16] Large-bodied Carnivores as a Model for Predicting Neandertal Home Range Size

Knowledge of Neandertal mobility patterns and territory sizes comes mainly from studies of lithic raw material movement across the landscape. We recently used climatic and ecological variables, pack size, and ranging behavior in wolves (Canis lupus) as an alternate means to predict Neandertal home range sizes, and concluded: (1) if Neandertals had a heavy dependence on large mammals, then even small social groups would have required large territories; and (2) estimates from the wolf model accord well with estimates from lithic transport, which lends support to the idea that raw material procurement was embedded in Neandertal subsistence mobility. To further refine the model, we examined prey biomass, group size, and home range size in African carnivores (Panthera leo, Crocuta crocuta, and Lycaon pictus) to delineate the effects of competitive interactions between species on home range dynamics. These data show a dramatic effect of social dominance, going from a strong inverse relationship between prey biomass and territory size in lions, to a weak inverse relationship in hyenas, to a positive relationship in wild dogs. These results suggest that competitive dynamics within the Late Pleistocene Eurasian carnivore guild need to be factored into the model to predict Neandertal territory size.
Ciccone, Jason (Van Epps-Hartley Chapter NYSAA) and Juliet Morrow (Arkansas Archaeological Survey)  

[211] **Paleoindians in the Hudson River Valley: A View from the Cornpile Site**

Located near the well-known West Athens Hill Paleoindian quarry workshop/habitation in the Hudson River Valley, the Cornpile site is a recently discovered, comparatively smaller lithic workshop/habitation. Excavations conducted between 2008 and 2013 yielded a variety of tools and debris that can be classified typologically as Paleoindian. This presentation will focus on the identification of lithic tools and debris using the organization of technology approach. Comparisons between the Cornpile site lithic artifacts with those from other Paleoindian sites in the Northeast will be made in order to place the site within a temporal framework. Implications for the timing and duration of Paleoindian occupation in the Hudson River Valley will be discussed.

[214] **A Formal Theory of Politogenesis: Towards an Agent Simulation of Social Complexity Origins**

Agent-based social simulation models are beginning to make significant contributions to scientific understanding of origins of human social complexity (politogenesis). However, social theory remains unclear about the prerequisites of social complexity origins; about things people must have known before the simplest societies could self-organize. In addition, there is a paucity of formal theories of politogenesis. I present a formal mathematical theory of social complexity focused on the phase of human history preceding its initial emergence in selected world regions ca. 10,000 years ago (early Holocene epoch). The formalism uses probability theory and analysis to derive a set of basic, testable results. The main prediction of the theory supports the rare nature of initial social complexity, consistent with observation. Further geospatial applications of the theory predict expected locations for politogenesis, based on prior, causal, theoretically predicted potentials.

Ciolek-Torello, Richard (Statistical Research, Inc.) and Bradley Vierra  

[294] **Agricultural Dependence and Sedentism in the Southern Chuska Valley**

Two general models describe the transition to a sedentary, agricultural way of life in the Southwest. One suggests that agriculture and sedentism are closely linked and came quickly following the introduction of agriculture in the Late Archaic period. Following this model, a distinctive pattern of domestic organization developed early and persisted essentially unchanged throughout prehistory, despite substantial changes in architecture and household structure. The second model suggests that agricultural dependence and sedentism came perhaps as much as a thousand years later because people initially used agriculture to maintain a hunting and gathering economy. Proponents of this model argue that agriculture and sedentism function independently and that intensive agricultural production preceded sedentism. This second model emphasizes changes in architecture, storage, material culture, and demography as well as agricultural diversification and the development of agricultural technologies as indicators of changing economies and mobility patterns. In this presentation, we examine these opposing models using architectural and subsistence data from the NM-491 project.

Cipolla, Craig (University of Leicester)  

[338] **Introduction: Globalizing the Local and Localizing the Global at Mashantucket**

The first half of this paper introduces the session (Indigenous people and foreign things) by outlining the advantages and goals of studying indigenous history and archaeology from the perspective of consumption. The paper begins by setting the historical context for the session and then moves on to consider the major themes and theories that cross-cut the papers that follow. In order to illustrate the key themes and challenges involved in studying indigenous consumption, the second half of the paper draws upon examples from the Mashantucket Pequot Reservation in southeastern Connecticut. We focus specifically on Pequot consumption in the eighteenth century. Through this brief case study we begin to wrestle with the complexities of colonial consumption in Native New England, asking if it is possible to distinguish between economic hardship and the perpetuation of cultural traditions in Mashantucket
households.

Claassen, Cheryl (Appalachian State University)

Abundance for Thanksgiving and Renewal
Wealth for native people, like modern people, was visible in abundance—of offspring, of generations, of food, of repeated success in endeavors. These states of living and those countable items were gifts from deities or spirits who expected thanksgiving and reciprocity from the individual or family so blessed. Also involved were the concepts of bone soul and stone soul, such that an accumulation of bone, stone, or shell created a renewal context. In this paper I will highlight Archaic eastern North American sites—from Missouri to Ontario—where abundance of items is evident and suggest that these were shrines of thanksgiving. Among these shrines are bone shrines, lithic shrines, and shell feasting loci where thanks were given and renewal was evoked.

Clark, Amy (University of Arizona)

Time and Space in the Middle Paleolithic: Spatial Analysis of Open Air Sites in France
The inability to unravel the many events, of variable duration, that led to the formation of individual archaeological sites greatly hinders our interpretation of these sites for all time periods and cultures. It is a particular challenge, however, for sites produced by the ephemeral and temporally discontinuous use of space that characterizes hunter-gatherer behavioral patterns. Discerning contemporaneity and/or intervals of time between events is often viewed as an intractable theoretical obstacle. Every site is a palimpsest of events of variable durations and separated by seconds to millennia. This presentation will discuss one attempt to unravel this complex, and elusive, aspect of the archaeological record through spatial analysis of open air, Middle Paleolithic sites in France. This study uses lithic refittings and the organization of space to delineate individual events and how they relate to each other, within time and space. These sites were excavated by INRAP, l'institut national de recherches archéologiques préventive, over a large spatial area and include a wide range of site-types, from raw material extraction sites to (potentially) short-term campsites.

Clark, Lindsey (PaleoWest) and Dean Wilson (New Mexico Office of Archaeological Studies)

Ceramic Variation and Occupation History of Site NM-Q-18-120
Site NM-Q-18-120 is a large multi-component site occupying a small knoll near the northern end of Reach 12A of the Navajo-Gallup Water Supply Project pipeline near Twin Lakes, New Mexico. PaleoWest conducted data recovery at this site prior to pipeline construction in 2012. Investigations defined five components ranging in age from early Pueblo II to unknown historic (A.D. 900-1880). Two Pueblo II period occupations were discovered and represent the most intensive occupation of the site. The later Pueblo II period occupation occurred during the Chaco era (A.D. 1050-1150) and consisted of a large roomblock and associated midden with a diverse artifact assemblage. The occupation history of site 120 will be discussed through the analysis of ceramics and the site will be examined in the context of the broader Chacoan occupation of the area.

Demographic Disparities between Baby Boomers (When Will I Retire?), Generation X (Why Can’t I Get a Promotion?), and Millennials (How Can I Get a Job?) in North American Archaeology
In North American Archaeology, there are three main demographic generations of practitioners. As baby boomers (1946–1964) struggle, or not, with decisions on when to retire there are direct impacts to generation X (1960s–1980s) practitioners as they attempt to promote up through the system. Also, there is the millennial generation (1980s–2000s) attempting to break into the industry via their first jobs after undergraduate and graduate school. It is apparent that there is still a vast disconnect between these three demographic generations when it comes to training, mentoring, and succession planning. I want to
explore this disconnect and discuss some methods that can be employed in Academia and the Cultural Resource Management (CRM) industry to more effectively bridge the gap between the three generations. Training, mentoring, and succession planning must begin in Academia at the undergraduate level and continue through graduate school. The CRM industry must also embrace this concept of continual training, mentoring, and succession planning in everyday business operations doing Section 106 compliance Archaeology in North America.

Clay, Vickie, Craig Young (Far Western) and Robin Michel (NAS Fallon)

Archaeological test excavations at a complex of sites in the western Carson Lake Basin, Range B-16 at Naval Air Station Fallon, reveal evidence of human use spanning Paleoarchaic to Late Archaic times in the western Great Basin. The open-air sites typically contain one or two components suggesting that each occupation can be correlated with a changing mosaic of mesic environmental conditions. Groundwater-charged springs and distributaries supported lakes with expansive shorelines and islands that provided, at times, attractive resource patches. Resource productivity is indicated by archaeological faunal remains including small game, fish, waterfowl, eggs, and mussels. Artifact assemblages include an elaborate array of ground stone and obsidian artifacts that vary across temporally discrete settings. Peaks of use intensity vary with water availability and wetland productivity across the Holocene.

Clay, R. Berle [263] see Hargrave, Michael

Clayton, Sarah (University of Wisconsin-Madison)

Archaeologists continue to debate the significance of interregional migration in bringing about the changes in material culture, settlement patterns, and political organization that mark the beginning of the Epiclassic Period in central Mexico. Migration is likely to have been an important factor in these changes, but it is more often invoked as an explanation for shifting material culture patterns than explored as a social process with varying outcomes at multiple scales, from regions to communities and households. Ongoing research at Chicoloapan Viejo, a settlement located in the southeastern Basin of Mexico, provides an opportunity to consider how processes of migration shaped local domestic practices, material culture, and community organization. In this paper I compare domestic architecture and material assemblages from Chicoloapan with those of contemporaneous settlements and discuss the implications of regional variation for understanding migration and multiethnicity during the Epiclassic period. Preliminary data from stratigraphically controlled excavations indicate that Chicoloapan’s Epiclassic settlement was temporally distinct from earlier occupations. These data also shed light on recent conceptualizations of a transitional, pre-Coyotlatelco, Early Epiclassic phase. Coyotlatelco pottery is stratigraphically associated with wares from the hypothesized early phase, reflecting variation in ceramic traditions across a multiethnic region during the Epiclassic period.

Cleghorn, Naomi (University of Texas Arlington) and Christopher Shelton (University of Texas Arlington)

The Knysna estuary and coastal environment (Western Cape, South Africa) present foragers with an attractive juxtaposition of diverse resources, a fact that has resulted in a rich Late Pleistocene archaeological record. Despite earlier reports of Stone Age sites in this area (Goodwin and Van Riet Lowe, 1929; Deacon, 1979), none have been systematically studied. We present a previously undocumented site – Knysna Eastern Heads Cave 1 or KEH-1, a sea cave east of the headland where the Knysna estuary meets the Indian Ocean. At 23 meters asl, the deposit is above the last Interglacial high sea stand and thus could potentially include deposits older than 125,000 years. We report preliminary age estimates and initial technological observations resulting from the first systematic excavation at KEH-1. A natural erosional face allowed us to investigate two components of the site. The upper deposit is a shell midden (likely LSA); while the deeper deposit (possibly MSA) lacks shell but is rich in archaeological features including sequential hearths, ochre, stone tool debris, and processed faunal remains. The analysis of KEH-1 is part of a larger research program that also includes the study of ESA, MSA, and LSA sites on the Western headlands.

[33]  The Development of a Distinctive Cave Methodology: A Retrospective Appraisal of the Petexbatun Regional Cave Survey

It is now generally accepted that cave archaeology’s basic theoretical and methodological approach developed during the Foundation Period [1980-1997]. My own experience in cave archaeology dates to the Naj Tunich Project in the late 1980s so I have had the opportunity to participate in much of the process. The greatest expansion of methodology occurred during the Petexbatun Regional Cave Survey (PRCS) from 1990-1993 as the project moved away from the investigation of a single cave that was treated as an isolated and independent site. The project’s focus on finding relationships between caves and architecture meant that caves had to be related to both each other and to surface features. The size and duration of the project generated an artifact assemblage of unprecedented size but more interestingly moved the project into consideration of material outside the usual definition of an artifact. Discussions of crystals, unmodified stones and speleothems became part of the cave literature as a result of the PRCS. Because of my own role in the discussion of speleothems, I will briefly discuss subsequent research and some unresolved issues.

Cobb, Charles (South Carolina Institute of Archaeology & Anthropology)
[338]  Feasting and Cosmic Debt

Debt and consumption are powerful inducements for the circulation of objects and privileges. In pre-modern as well as modern political economies, the manipulation of debt obligations promotes cycles in the disbursement of goods and services. These cycles are continually renewed by diverse patterns of consumption. In pre-Columbian southeastern North America, Mississippian communities (ca AD 1000-1600) frequently relied on feasting as a means of amassing impressive amounts of goods via networks of indebtedness; goods which were then consumed in highly visible venues and performances. Feasting in these contexts was instrumental to the reproduction of social distinctions. A primary driving force for these feasts may have been the need to satisfy what Julie Chu has referred to as “cosmic debt,” where goods were offered for consumption to ancestors and deities, thereby expunging spiritual obligations.

[275]  Surveying and Sampling Ancient Mexican Obsidian Sources: The Case for Total Surveys of Source Systems

This paper will discuss the achievements of several key programs which have studied major Mexican obsidian sources. After nearly five decades of investigations, some of these sources have not been rigorously defined in terms of the total extension of outcrop systems, possible internal trace element composition variations, and the detailed nature of prehispanic settlements, mines, and workshops associated with specific geological outcrops. The sources to be discussed include: the Sierra de Pachuca (Hidalgo), Ucareo-Zinapecuaro (Michoacan), regions surrounding Pico de Orizaba Volcano (Veracruz-Puebla), and Zaragoza-Oyameles (Puebla).

Coben, Lawrence (UPENN and the Sustainable Preservation Initiative)
[296]  Archaeology Should Be Applied and Relevant: Out of the Ivory Tower and into the Real World

Academic archaeology does not encourage engagement with the "real world"—there is no career benefit, and frequently such engagement is a detriment to career success. Numerous archaeologists do not consider making their work accessible to the public nor do they collaborate with the communities in which they work and of which comprises an important part of their jobs. Many consider cultural heritage preservation to be the responsibility of others. Community engagement, when it occurs, normally consists of a bit of explaining to local people the importance of their cultural heritage in the vague and unfounded hope that site destruction will not occur and that continued research onsite will be permitted. Archaeological social action frequently consists of letter writing and whining, without understanding of the social processes that underlie successful results in the political arena. It is small wonder then that archaeology and anthropology are underfunded and considered irrelevant in many quarters, from politicians to university presidents. In this paper I argue for an applied and relevant archaeology that
engages the public and provides true benefits to local communities and society as a whole.

Cobos, Rafael (Universidad Autónoma de Yucatán)  
[252] plaza Plaza Plans at Chichén Itzá, Yucatán, México  
According to some Maya scholars, plaza plans can be interpreted as mental maps or cognitive models related to specific social and/or cultural choices. Plaza plans mirror an “architectural grammar”, which was the result of having designed and built a distinctive environment used for social activities. Following this reasoning, data collected at Chichén Itzá is utilized to understand the possible role that plaza plans might have had before and during the apogee of this Maya site.

[293] Remembrance of Things Cast (and/or Hammered): Depositions of Metal Objects at the Cenote Sagrado, Chichén Itzá  
Through a binational collaboration among archaeologists, conservators, and physicists at UC Berkeley and the Universidad Nacional Autónoma de México, non-invasive, non-destructive methods were employed to characterize the “technological styles” of metals (n = 148), including bells, figurines, and sheet, recovered from the Cenote Sagrado at Chichén Itzá, Mexico. This project represents the first-ever effort to evaluate the Cenote metals from all three US and Mexican museums where they are held and reconciles multiple scholarly perspectives to infer the life histories of individual objects. We propose that these objects were deposited in ritualized events contemporaneous with Chichén’s primary occupation (A.D. 750-1050) and in the centuries thereafter and that they were originally fabricated in such places as West and Central Mexico, Lower Central America, and Colombia. We documented the objects with optical microscopy (visible, ultraviolet, infrared light) and determined bulk compositions with Energy-Dispersive X-Ray Fluorescence spectrometry. The assemblage contains gold-copper alloys and copper-based metals, including alloys with arsenic and/or tin. We performed Rutherford Backscattering Spectroscopy and X-Ray Diffraction on 15 metals to learn about compositional differences between their surfaces and bulks; the golden surfaces of certain bells arose from the alloys employed while those of certain sandals emerged from artificial gilding of copper substrates.

Codding, Brian (University of Utah)  
[284] Risk, Gender and Long-Term Ethnography: Examining the Origins of Australia’s Desert Societies  
Australia’s desert societies are known for a number of characteristics, including the importance of women’s foraging labor, land-use practices focused on fire-stick farming, and an estate system of land-tenure. While early work suggested that these societies were static through prehistory, detailed ethnographic work combined with an archaeological record of long-term human-environment interactions provides a window to investigate changes in these patterns over time. Drawing on Michael Jochim’s treatments of resource acquisition risk, gender-specific foraging patterns and archaeology as long-term ethnography, I highlight one potential explanation for the emergence of Australia’s desert societies.

[324] Materials and Technological Analysis of Perishable Artifacts from Bonneville Estates Rockshelter (26EK3682), Nevada  
Archaeologists have questioned whether variations detectable in the archaeological record are evidence of ethnic boundaries or regional environmental adaptations. Perishable artifacts are one class of artifacts
that exhibit regional variations, and rockshelters and dry caves in the Great Basin are unique sources of preserved perishable artifacts. Bonneville Estates Rockshelter (26EK3682) in Elko County, Nevada, has produced perishable artifacts spanning from the Paleoindian to historic periods, and it provides an excellent opportunity to compare multiple occupations on the western edge of the Bonneville Basin. In this current study, an analysis of raw material, technology, and style of perishable artifacts from Bonneville Estates is used to address issues of ethnic and geographic boundaries in the Bonneville Basin during the Late Archaic, and this study can be applied to questions of Late Archaic, Fremont, and Numic identities. This pilot study is part of an ongoing analysis that will incorporate perishable artifacts from throughout the Bonneville Basin.

Coello Rodriguez, Antonio [256] see Smit, Douglas

Cofelice, Jessica

In September 2009, archaeologists from Independent Archaeological Consulting, LLC (IAC) of Portsmouth, New Hampshire completed the disinterment of the Legro family burial ground, encountering the remains of four adults and seven children. The burial ground was once located in a quiet corner of the Legro family farm in Rochester, (Strafford County) New Hampshire. Modern highway construction drastically altered the historic landscape, leaving the burial ground isolated within the Exit 15 off ramp alongside NH Route 16. When proposed highway construction required relocation of the burial ground, the subsequent archaeological excavations resulted in the discovery of a myriad of burial treatments spanning the dynamic period between 1800 and 1865 leading up to the development of the modern funerary industry. Analysis of the Legro funerary hardware assemblage in terms of material culture provided historic archaeologists with a unique case study to demonstrate how an increase in hardware complexity parallels a shift in mortuary consumer behavior. In addition, the shift in material culture coincides with the transition from home based burial practices to a reliance on professionals trained to manage the new American way of death.

Coffey, Grant (Crow Canyon Archaeological Center) and Kristin Kuckelman (Crow Canyon Archaeological Center)

[333] Public Architecture of the Goodman Point Community, Southwestern Colorado, A.D. 1000 to 1280

The Goodman Point area of southwestern Colorado was home to a successful and enduring Ancestral Pueblo community that grew into perhaps the most populous aggregation of farming families in the northern San Juan just before region-wide, permanent depopulation by Pueblo peoples around A.D. 1280. Recent excavations by the Crow Canyon Archaeological Center have produced comparative data for a variety of public structures once part of the Goodman Point Community, including multiple great kivas and bi-wall structures, which were built cooperatively and used by members of this large community during its 200-year occupation of that landscape. These constructions served to integrate the community, order society, and create a unique and unifying social identity for the residents. The architectural and stratigraphic data for these public structures, coupled with their broader spatial and temporal contexts, suggest that the forms, uses, and functions of public structures evolved throughout the history of the community, and that the objectives and mechanisms of integration were adapted to mediate new social environments and challenges. The patterns observed suggest an intensification of integrative strategies as well as the emergence of novel integrative schema in the decades just before final regional emigration.

Cohen, Susan (Montana State University)

[127] The Uses (and Abuses) of the Beni Hasan Tomb Painting for the Archaeology of Middle Bronze Age Palestine

One panel of the famous painting found in the tomb of Khnumhotep II at Beni Hasan depicts the arrival of a group of “Asiatics” bringing goods to the nomarch. As one of the only depictions of its kind dating to the Middle Kingdom, and one of the few pieces of evidence that connects Middle Kingdom Egypt with Middle Bronze Age Palestine, this tomb painting has received perhaps more than its fair share of attention, and
has been used to illustrate everything from speculations on patriarchal physiognomy to discussions of Canaanite craftsmanship. In addition, the Beni Hasan painting figures prominently in debates regarding the chronological correlations between these two regions. In short, a great deal has been attributed to this painting, resulting in numerous longue durée analyses based on the interpretation of a specific événement—the painting depicts the isolated event of the arrival of a single group, which is then depicted in one specific mortuary context. This paper will examine the many uses, and occasional abuses, of the Beni Hasan tomb painting as the documentation of a “quotidian event” as well as a crucial datum for broader interpretations and discuss the significance for the archaeology of Middle Bronze Age Palestine.

Cohen, Anna (University of Washington)

[200] Political Authority and Domestic Economy at Angamuco, Mexico

Throughout their development, new regimes must establish political legitimacy, which involves co-opting existing local institutions and creating new administrative, economic, and ideological systems. An important aspect of this legitimizing process is negotiating with manufacturers and craft producers such as potters. Previous research in imperial contexts has shown that potters may be subject to top-down state directives in terms of raw material selection, material recipes, and labor organization, but that they also retain local knowledge and practices. Ethnohistoric data in western Mexico suggest that the Purépecha (Tarascan) regime controlled technological production including pottery; however, archaeological data from related imperial contexts indicate that agent-mediated craft production occurred throughout broader imperial changes. In this paper, I explore how political changes in the Postclassic (1000-1520 C.E.) Purépecha regime impacted ceramic technology at the ancient city of Angamuco, Michoacán. This examination is supported by artifacts recovered from the ongoing excavation of domestic and public architecture at Angamuco.

Coin, Emily (Bowdoin College)

[292] A Cache Economy: Analysis of a Late Classic Cache at Maax Na, Belize

During the 2001 field season, excavations in the Ceiba Group, a small elite residential complex at the large site of Maax Na, Belize, uncovered two Late Classic face pot caches. One of these was empty; the other one contained a number of materials that were originally analyzed by Leslie Shaw in the field. These included obsidian, Spondylus, greenstone, and ear flare fragments that originated from different parts of the Maya area. This paper’s goal is to use Shaw’s analysis as well as information about the vessel form to reconstruct multiple layers of Maya relationships: among residents of Maax Na, among sites in the Three Rivers Region of Belize and Guatemala, and between Maax Na and the coastal sites where many of the cache objects seem to have originated. This multiscale approach will tie together the various local and non-local levels while placing the cache within the context of the site itself. The presence of non-local goods will be of particular use in shedding light on Maax Na’s economy and regional and interregional ties.

Coinman, Nancy and Jake Fox (Radford University)

[71] The MP/UP Transition and Early UP in the Wadi al-Hasa: Paradigmatic Changes in Levantine Prehistory

Stemming from Geoff Clark’s original paleolithic projects, research in the Wadi al-Hasa (Jordan) at paleolithic sites provides new evidence of important technological changes and variations in settlement organization that differ from earlier Levantine interpretive frameworks. The transition from Mousterian technology to the Early Upper Paleolithic Ahmarian at Tor Sadaf rockshelter is presented with an emphasis on in situ technological changes. Survey data for two very large Upper Paleolithic “basecamps” in the Hasa are reinterpreted using excavation data from Ain al-Buhayra (WH5 618, Spring Complex) and Tha’lab al-Buhayra (EHLPP 2), showing intriguing variations on small camp organization and activities.

[156] Chemistry and Society: Investigating Pueblo II-Pueblo III Mural Paint in the Northern San Juan

We discuss results of chemical analyses of blackened plaster in a Pueblo III kiva at Turkey Pen (42SA3714), southeastern Utah, and white designs on reddish-brown plaster in late Pueblo II–Pueblo III kivas at Lowry Pueblo (5MT1566), southwestern Colorado. Turkey Pen samples were examined with
scanning electron microscope (SEM) microphotographs and by dispersive x-ray (EDX) elemental analyses of plaster surfaces. The findings challenge common and long-standing assumptions of fire-blackened walls by pointing to periodic applications of (black) calcium oxalate in wet slurry. Calcium oxalate (associated in nature with water/moisture) and the color black are consistent with historical Pueblo concepts regarding the significance of water and kivas as the Underworld. Ongoing investigations of painted designs in Kiva B at Lowry Pueblo indicate contemporaneous use of multiple pigment types, design schemes, and ritual layouts. X-ray fluorescence examinations detected high levels of lead and zinc (ppt) that raise interesting questions about mineral sources, exchange networks over time, and the health and social consequences of lead use. Present research is focused on resolving sampling and testing inconsistencies (possibly linked to modern mural conservation), collecting comparative data, and locating sources of galena with high zinc.

Cole, Michelle, Daniel Sandrowicz, Katharine Craig, Kate Adam and Kirk Smith

Geophysical Investigations of the Walter L. Main Circus Train Accident in Tyrone, Pennsylvania

During the Memorial Day weekend in 1893, a train carrying the Walter L. Main Circus failed to navigate the slope and curves on the Pennsylvania Railroad down the Allegheny Front. The train derailed near the town of Tyrone, Pennsylvania. Five people lost their lives, and countless horses were killed in the crash. Exotic animals including lions, tigers, zebras, and a gorilla named “Man-Slayer” escaped their cage cars; some preyed on local livestock and were subsequently shot by locals and circus employees. The animals were buried in a mass grave located near the wreck site. Geophysical investigations including ground-penetrating radar, electrical resistivity, and magnetometry were conducted during the fall of 2013 to locate the circus train mass grave. Remote sensing was followed by limited ground-truthing in the form of shovel test pits. This poster is an overview of the results obtained through the above described archaeological investigations.

Collard, Mark (Simon Fraser University)

Risk, Mobility, or Population Size? Drivers of Technological Richness among Contact-Period Western North American Hunter-Gatherers

Identifying factors that influence technological change in small-scale societies is important for understanding human evolution. There have been a number of attempts to identify factors that influence the evolution of food-getting technology, but little work has focused on the factors that affect the evolution of other technologies. Here, we focus on variation in technological richness (total number of material items and techniques) among recent hunter–gatherers from western North America and test three hypotheses: (1) technological richness is affected by environmental risk, (2) population size is the primary determinant of technological richness, and (3) technological richness is constrained by residential mobility. We found technological richness to be correlated with a proxy for environmental risk—mean rainfall for the driest month—in the manner predicted by the risk hypothesis. Support for the hypothesis persisted when we controlled for shared history and intergroup contact. We found no evidence that technological richness is affected by population size or residential mobility. These results have important implications for unraveling the complexities of technological evolution.

Stability and Change in European Neolithic and Early Bronze Age Agricultural Systems

After farming was established in Europe in the early Neolithic agricultural systems became increasingly regionalized, with a greater diversity of crops and cultivation practices. We use a data set of 14,000 archaeobotanical records from over 300 Neolithic and early Bronze Age sites in northwest Europe to compare regional patterns in the use of domestic cereal and pulses species and to assess diachronic changes with respect to climate, culture and demography, and in particular to population ‘booms and busts’. Whether or not crops were chosen to suit certain environmental conditions or were selected in response to cultural preferences will be discussed.

Imperiled Monument Documentation and 3D Virtualization at the Formative Period Site of Chalcatzingo, Morelos, Mexico

Chalcatzingo, famous for its bas-relief stone sculptures and carvings and extensive Olmec-style monumental art and iconography, has important information to yield about Formative culture. The World Monuments Fund has placed the Central Highland Mexico site on the World’s 100 Most Endangered Monuments Watch List. Using best available technologies and analytic approaches for Mesoamerican heritage is an urgent priority due to loss and damage occurring at unprecedented rates. Previous stone monument documentation efforts at Chalcatzingo have included standard photography, drawings, rubbings, and molds. Although these efforts can reveal details, they can also be subjective and destructive, creating and accelerating monument surface deterioration. Coupled with erosion and impacts from acid rain and air pollution, monuments are showing signs of weathering at alarming rates. A collaborative pilot project, including new types of terrestrial laser scanning, photogrammetry, rapid prototyping, and 3D virtualization are being used to document and analyze the site’s fragile monumental record, creating new ways to communicate the past to the public and changing the way we teach, learn, and interact with heritage. Results from our pilot efforts demonstrate new potential for iconographic studies and offer innovative means for addressing long-term management, protection, and research analysis.

Collins, Ryan (Brandeis University)

Hitting Bedrock: Formative Foundations in Yaxuna’s E Group Plaza

E-Groups, emergent in Middle Formative Maya society, are defined in part by the presence of three architectural features, a western radial pyramid, an eastern range structure, and an extensive plaza separating them. Often recognized for their monumentality, E-Groups are interpreted as being among the earliest architectural markers of a cohesive Formative Maya tradition in the Lowlands of Mexico, Guatemala, and Belize. Yet, little research has focused on the plazas of E Groups as they were assumed to be vacant spaces. Recent excavations in 2013 at Yaxuna, Yucatan, Mexico challenges this assumption. The Yaxuna example is recognized as an outlier in relation to the vast majority of E-Groups in the distant Southern Lowlands. Assemblages of architectural walls, platforms, stucco floors, ceramics, and a diversity of lithic tools suggest that the plaza was once a bustling social center implicating vast networks of exchange through the Middle and Late Formative periods, though the extent of the plaza’s function remains unclear. The changing understandings of the social and physical landscape of E-Groups could have profound impact on past, present, and future understandings of the ancient Maya and gives us pause to reconsider this important monumental feature in everyday Maya identity, exchange and sustainability.

Collins, Angela and Melody Pope (The University of Iowa Office of the State Archaeology)

Seeing the Forest through the Trees: Interpreting Distributions of Macro and Micro-scale Materials

Recent excavations at the Palace Site, a North American Middle Archaic habitation, have focused on the recovery and mapping of fine-scale micro and macro materials. While macro artifacts are often the focus of spatial analyses that inform about site structure and activities, microdebris recovered from flotation processing is typically viewed only as a source of data on paleodiet and environment. In our work we have expanded the analysis of microdebris as a compliment to macrodebris in order to provide a more nuanced interpretation of on-site tasks and activities. Our poster will visually present the spatial relationships of micro and macro debris distributions and illustrate the combined potential of both data sources to provide a more detailed account of hunter-gatherer lifeways.

Collins, Michael (Gault School of Archaeological Research)

Evidence for Older-than-Clovis Occupation at the Gault Site, Texas

Stratigraphically below the Clovis component at Gault, excavations have penetrated valley alluvium some 80 cm thick and reached limestone bedrock in 12 m² of Area 15. Deposits consist of fluvial gravel, overbank silty clay, colluvium, and quartz-rich eolian dust and yielded approximately 13,000 pieces of chert flaking debris and some 60 chipped stone tools. The stratigraphic integrity of this early material is quite secure. Analysis continues, so findings are preliminary. Faunal preservation is very poor, with only teeth of bison, horse, and mammoth recovered. Artifacts of chert include knapping debris, cores, blades, bifaces, stemmed projectile points, and a variety of tools on blades and flakes. Overall the Older-than-Clovis assemblage at Gault shares some traits with Clovis but also exhibits traits decidedly unlike Clovis, notably the small stemmed projectile points, but also the details of biface manufacture and such tools as
a small serrated knife and a beak on a flake. It is not yet clear whether recovered artifacts represent a single, coherent assemblage or if a different interpretation will emerge.

Collins, Joe (University of Texas at El Paso) and Patrick O'Grady (University of Oregon Museum of Natural and Cultural History)

[324] Geoarchaeology at Rimrock Draw Rockshelter (35HA3855): A Progress report on Geologic Investigations at a Deeply Stratified Paleoamerican Site at the Northern Great Basin Periphery of Southeastern Oregon

In the summer of 2013, geoarchaeological investigations were focused on the evaluation of deep excavation blocks and a backhoe trench bisecting a relict stream channel downstream from Rimrock Draw Rockshelter. Excavation is producing Western Stemmed projectile points from deposits approaching a depth of three meters, and artifacts associated with fluted point technology have been surface collected from a terrace north of the stream channel. Over 1,120 sediment samples were collected from 41 auger probes and 21 column samples from within the data recovery units. Sediments are being analyzed at the University of Texas at El Paso for grain size, strontium isotope ratios, mineralogy, and total organic carbon. These data also are complemented by 92 pXRF analyses collected in association. This presentation focuses on 14 sediment samples and pXRF data collected from Column 1 within the West wall of Unit 2. The samples were analyzed for grain size using standard protocols for laser diffraction analysis of sediments. Elemental data were plotted against depth. Preliminary data analysis suggests major environmental shifts at 256 cmdb and 164 cmdb, with AMS dates pending.

Colston, Jessica (California State University Los Angeles), Richard Guttenberg (California State University Los Angeles) and Rene Vellanoweth (California State University Los Angeles)

[316] Spatial Distribution of Bone Tools from the Tule Creek Village (CA-SNI-25) on San Nicolas Island, California

Bone tools on San Nicolas Island are quite rare when compared to the relative abundance of stone and shell artifacts. The Tule Creek Village (CA-SNI-25) is a late period site occupied as early as 2,000 B.C.; however, the site’s most intensive occupation was from A.D. 1400 to European contact in the late 1700s. The East Locus has many ceremonial features, including double and triple dog burials, feast pits, and helically aligned hearths which date to the main occupation period. In contrast, Mound B is multicomponent loci, but does not contain any comparable features. Of the more than 4600 artifacts currently catalogued, only 59 (1.3%) artifacts are made from bone. This poster analyzes the bone tool assemblage based on the taxon of material, type of tool, and spatial context. Analysis of the bone tool assemblage will give us a better understanding of the faunal resource utilization at the Tule Creek Village during the Late Holocene.

Coltman, Jeremy (California State University, Los Angeles)

[37] Chaos and Cosmos: Ceremonial Circuits and Ethnomedicine in the Art and Ritual of Mesoamerica and the American Southwest

One of the salient and enduring features of cosmology found among the peoples of Mesoamerica and the American Southwest is the quadripartite representation of the universe with a sacred center, or axis mundi. These mandala-like models are central artistic expressions of indigenous knowledge that can often reflect concepts of disease, curing, balance, purity, and pollution. The body itself becomes a model of the cosmos, which is constantly threatened by antisocial agents of chaos. By invoking a mythic time of creation, the invisible drama of the universe plays out in the patient. This study will offer a comparative analysis of such rituals in Mesoamerica and the American Southwest, with a particular focus on Central Mexican codices, Navajo sandpainting rites, and contemporary Nahua rituals from Veracruz. These spatial concepts are more than just a shared color-directional symbolism, since striking similarities also exist in form and function. While this study is admittedly broad in both time and space, it aims to add to the discussion of interaction between Mesoamerica and the American Southwest.

[295] Detection Based Modeling for Wide Area Archaeological Site Inventory and Evaluation: A New
Decision Support and Archaeological Landscape Research Tool
Section 110 of the National Historic Preservation Act of 1966(as amended) requires each Federal agency
to establish, “a preservation program for the identification, evaluation, and nomination to the National
Register of Historic Places, and protection of historic properties.” On ground survey and evaluation in the
service of this has proven prohibitively expensive. Because there are no clear timelines for this, no
Federal agency has completed survey and evaluation. In the absence of comprehensive survey and
evaluation, important sites remain undocumented and unprotected, and there is no sound decision
support prior to conducting 106 surveys. Archaeological predictive models (APMs) have, in the half-
century since they were devised, proven too unreliable for widespread adoption due to problematic
assumptions and inappropriate statistical techniques. We present a site detection protocol based on
Bayesian statistical analysis of direct returns from a variety airborne and satellite remote sensors,
including those that collect multispectral, hyperspectral Lidar, and synthetic aperture radar data. This
direct-detection based model identifies significant site, disturbed site, and insignificant site locations, and
thus serves as a de facto Section 110 survey. This paper also serves as a case study in data-matrix
approaches to remote sensing rather than more common image enhancement techniques.

Compton, Anne (University of Michigan)
[108] Trade Dynamics, Political Economies, and Household Variability: An Examination of Daily Life
in the Bono Manso Region
This paper examines how household economies vary and are shaped by integration and interaction with
regional political and supralocal exchange networks. Bono Manso, the capital of the Bono polity in
Ghana, and its satellite villages were located along trade routes that initially linked them to the Inland
Niger Delta and later with Atlantic coastal settlements. Bono Manso dates to the late 12th through 18th
centuries AD, spanning both the zenith of the gold trade and the Atlantic Trade era. Since data are
scanty, scholars often disagree about Bono Manso’s role as the capital of a state, the extent of its
centralization, and its economic control over neighboring villages and provinces. By focusing on a
hinterland village, I examine how a community interacted with the larger center (Bono Manso) and how
that interaction shaped production, consumption, status differentiation, and labor organization from the
sub-Saharan to the Atlantic Trade eras. This paper examines: (1) how households and their domestic
activities were affected by interaction with the political economy of Bono Manso, (2) how integration
shaped household participation in regional and global exchange networks, and (3) the evidence for
change and continuity over time.

[340] Site Location and the Transition to Maize Agriculture: A Middle Ohio Valley Example
This paper explores the changes in site location preferences which accompanied the shift to an agrarian
lifestyle in the Middle Ohio River Valley. Criteria including distance between sites, distance to earthen
mounds, distance to rivers, and soil types were documented for both Late Woodland and Fort Ancient
sites in Southwest Ohio. These data were incorporated into a multivariate model which suggests that in
addition to dramatic shifts in subsistence and settlement patterns, Fort Ancient maize agriculturalists
preferred to live further apart yet closer to earthen mounds than their Late Woodland predecessors.
These findings are related to issues such as inter-village boundary maintenance and integrative
processes associated with social memory, factors which are evident in many early Neolithic communities.

[113] Species Diversity, Standardization, and the Spatial Organization of Production at Pueblo Bonito:
A Case Study from Chaco Canyon
The coalescence and transformation of many dispersed farming communities in and around Chaco
Canyon, New Mexico during the Bonito phase (850-1140 C.E.) is one of the most widely cited cases of
emergent sociopolitical complexity in pre columbian North America. Since the earliest investigations in Chaco, nearly 4,000 bone artifacts have been recovered from 15 sites throughout the canyon. Manufactured from the remains of at least seventeen different mammal and bird species, these objects range in form from decorative beads, pendants, tubes, and whistles to awls, needles, and scrapers, the latter of which were essential tools in perishable craft industries such as basketry, textiles, and hide-working. Recent analysis of raw material choice in bone tool manufacture revealed an intensification of basketry and hide production at an early stage in the development of Chacoan society. Expanding on that research, this study explores temporal trends and the spatial organization of craft production at the Pueblo Bonito great house. Preliminary results reflect preferential access to rare and exotic species relative to other sites in the canyon and a high degree of standardization in tool manufacture. The identification of several craft production loci has important implications for understanding economic organization and the gendered use of space.

[27] The Dynamics of Public Space in Ancient Nasca
Public places of congregation varied greatly in their size, elaboration, function and location in Nasca over a period of 1500 years. This study focuses on the dynamic use of public space at the site of La Tiza and compares it with wider developments in the region. The Late Formative (300 B.C.E.-A.D. 100) was a period of competition and growth when public spaces were found within and between sites. During Early Nasca (A.D. 100-450) as society became more integrated and complex, plazas were no longer located at settlements; instead large gatherings occurred at ceremonial centers (most notably Cahuachi) and the geoglyphs. In Middle Nasca (A.D. 450-550) plazas were once again located within sites as the power of the ceremonial center of Cahuachi declined, and their function likely changed. Middle Horizon (A.D. 650-1000) domestic sites have little evidence for public space, which may be related to a dramatic shift in elite culture and a focus on new mortuary practices. Following a period of abandonment and resettlement, Late Intermediate Period (A.D. 1200-1476) sites had small plazas and hilltop gathering areas. These changing dynamics of public space were related to shifts in various aspects of sociopolitical organization, regional integration, and religious practices.

[180] Studies of Black-Gloss Pottery from Monte Pallano (Italy) III: X-ray Fluorescence
This is the third of a series of four papers that report multi-faceted studies of a collection of 200 sherds of black-gloss pottery (a type of fine ware that was used for dining and wine consumption from the 5th century B.C.E.-1st century B.C.E) excavated from the Monte Pallano ridge in the Abruzzo region of eastern Italy. Customarily, pXRF has been used to identify and characterized clay sources for ancient pottery production, but pXRF data for the Abruzzo has not been reported until now. In this paper, the elemental composition of the ceramic fabrics—measured with a Bruker Tracer III SD pXRF—are analyzed to characterize the composition of locally-made black gloss, to distinguish local pottery from imports, and to relate this approach to fabric groupings that were made using traditional ceramological techniques. By comparing the pXRF data of local and imported black-gloss from the two sites and comparing the data to macro-observations of fabrics, this study aims to increase our understanding of patterns of exchange among the Samnites, Romans, and other peoples who populated this region of Italy.

[228] Continental Shift: The Search for New Field Sites in Asia and Europe during the Age of the Field School

The paper argues for the importance of shifting research areas mid-career. (Im)Practical points about this process are made while following the author on a search for new field sites in Southeast Asia and Europe. A decade should be considered sufficient time span to conduct meaningful research at one project location. Arguments are fine-tuned and retooled but redundant without new data streams for comparison. Mindful of field schools as the primary funding source, location decisions are made not only on the basis of research questions but on the practicalities of field work with thirty students. So is it Vietnam or Ireland? Decision forthcoming.

[152] Co-creation as an Essential Means toward Open Authority in Archaeology

Based in constructivist educational theory and using participatory museum and open authority models, this paper examines products co-created by visitors, volunteers, students, and museum staff at the C.H. Nash Museum at Chucalissa. Two case studies are featured. First, an exhibit on the African American Cultural Heritage of Southwest Memphis based on the excavated materials from a 1920s era farmstead that was co-created with University of Memphis and neighborhood high school students. Second, using curated collections, a set of education products and museum exhibits co-created by avocational archaeologists, and museum studies graduate students. Critical to the co-creation process is incorporating the authoritative voices and decisions of all participants. This paper argues that co-created products are ultimately more robust and relevant to the public than projects that incorporate only the voice of the professional community. As well, co-creative processes in archaeology serve as a vital link to educating the public on opportunities for engagement and the funding needs of cultural heritage institutions. Co-creation forms an essential opportunity for sharing with the public the authority and responsibility for the curation of a community’s cultural heritage.

[193] Mobility, Territoriality, and Costly Signals in Middle Woodland South-Central Ontario: Using Network Models and Evolutionary Ecology to Predict the Locations and Characteristics of Central Places in the Archaeological Record

The Middle Woodland period in south-central Ontario, often unfairly relegated to the periphery of the so-called Hopewell Interaction Sphere, has a significant and well-documented record of sites dating to the second millennium B.P. As well as numerous smaller task-specific locations, the record also includes multiple occurrences of burial mounds, including larger mortuary landscapes with significant earthworks. The setting of many of these sites along major waterways has not escaped attention, with several investigators asserting their role in establishing band or macro-band claims to key resource locations along ancient travel routes. In this paper I formalize and test this hypothesis by first considering the resource landscape and then via a simulation model establish forager mobility through the hydrological network to establish high value locations. Next, with reference to evolutionary ecology, I develop predications of the circumstances and manners in which social foragers would choose to establish and defend such high value locations. The paper concludes with a test of the predictions against the archaeological record, and shows that there is sufficient concordance to strengthen the hypothesis that Middle Woodland communities were using costly signaling to establish and maintain tenure over high value locations in the regional system.

[149] How Green Was My Valley? Reconciling Regional and Local Paleoenvironmental Signals at PPNA el-Hemmeh, Jordan
The relationship of environmental change to early human experimentation with plant cultivation remains a critical focus of research into the emergence of food production in Southwest Asia. Regional paleoenvironmental data are vital to investigating this relationship, but such data pose two fundamental questions: to what degree are regional data locally applicable, and are such data of the spatial and chronological resolution suited to anthropological explanation of human behavior? Links between environment and human behavior were likely articulated through very local experiences—i.e., distributions of water and vegetation, availability of animals, and relationships with neighboring communities. At the PPNA site of el-Hemmeh, Jordan, the proximity of the early Neolithic settlement to a paleoenvironmental archive of paludal sediments offers the chance to compare regional and local data. Stratified in-stream wetland deposits dating to the Late Pleistocene/Early Holocene a scant 200 m upstream from the site provide (a) evidence of local landscape morphology and conditions, and (b) a uniquely local paleoenvironmental record. We discuss here ongoing research into these paleoenvironmental proxies, the articulation of these records with regional paleoenvironmental data, and the implications of these findings for understanding the processes and environmental contexts of early experimentation with agriculture in the Southern Levant.

[259] Household and Community Scales of Post-Famine Demographic Change in Western Ireland
While the national demographic ramifications of the Irish potato famine in the late 19th century are well documented, the full spectrum of its social and psychological impacts has yet to be comprehensively studied. Individual family histories reveal the private rational(s) for splitting or relocating families, yet these are not necessarily generalizable to the population level; conversely, population-level studies cannot reveal the complex personal context of migration. Considering these together allows us to more vividly describe how changes in environment and social identity possibly informed individual decision-making. In this paper, we combine historical documentation, excavation, and oral histories to analyze the complex reasoning for migration and the particularities of relocation. We explore the realities of migration and depopulation through comparison at the most minute level—who leaves, who stays, why this occurs, and what it means for both people at home and abroad. By examining this phenomenon on the microscale, we are able to draw broader implications concerning the decision-making processes of both willing and unwilling participants in the Irish diaspora. Reaching into the 20th century with global implications, the migration of millions from Ireland created a rapidly changed environment for its citizens and others, both at home and abroad.

Conyers, Lawrence (University of Denver)
Ground-penetrating radar (GPR) reflection profiles were collected at Muge shell mound in 2012 using 400 and 270 MHz antennas. Energy penetration and reflection with the 270 MHz antennas was at least 4 meters with feature resolution to about 30 cm. The 400 MHz antennas were capable of lesser energy penetration to only about 2.5 meters, but with much better feature resolution. Reflection profiles, topographically corrected, show a distinct reflection from the base shell-early Mesolithic surface, which was the original ground surface on which burials have been excavated. The GPR profiles also display a number of features within the shell midden strata including a hard-packed living surface, or some other constructed layer, along the crest of the mound within the shell deposit. There are also a number of intrusive features that are likely burials. One rectangular feature with a distinct floor and objects on it was discovered on the western side of the mound, which is scheduled for excavation in 2013. This GPR test at Muge shows the utility of the method for defining shell stratigraphy, constructed or modified features within shell deposits and potentially objects or even architecture along the ground surface where the shells were originally deposited.

The Energetics of Mycenaean Defenses: Sociopolitical Implications of Fortification Construction in the Late Helladic Period (ca. 1600-1100 B.C.)

Fortifications are a well-known feature of Mycenaean Greece, but have been relatively underutilized as a way of exploring the settlement systems and regional political hierarchies that emerged during the Late Helladic period (ca. 1600-1100). In an effort to refine our understanding of Mycenaean political geography, this study adopts an energetic perspective on fortifications, and focuses on the scale of labor invested in their construction. Energetics provides a framework for systematically calculating and comparing the labor costs of construction for various structures (in “person-days”), and uses such costs to infer relative differences in political power among groups and communities through the implied differences in labor control. My research generated labor costs for thirty-six LH fortifications, located across eight regions of the Aegean. These were then analyzed in a regional context, and evaluated against independent settlement surveys to determine how differences in the investment of labor correspond to what is known of the regional hierarchies of power during the LH period. Ultimately, my results intend to measure the strength of the connection between monumental construction, labor mobilization and elite authority on a regional level, as a way to reassess the political landscape from the perspective of labor control.

Geoarchaeological Analyses of Redeposited Artifacts from McFaddin Beach, Texas

For over 50 years projectile points have been found and collected along McFaddin Beach in Jefferson County, Texas. These artifacts range in age from the Late Pleistocene to the mid to late Holocene. While most of the points have been picked up by collectors, these individuals have recorded provenience data for a large number of the artifacts. This study uses GIS and statistical analyses to recognize spatial patterning of projectile point distribution, Clovis points in particular. These analyses will in turn enable the creation of GIS and sedimentological models using artifact weight and shape, longshore drift, ocean currents, and other factors to identify the most likely offshore locations from which the artifacts originate. The results of this research will allow archaeologists to target these areas for future excavation and better understand the Clovis presence on the Texas continental shelf.

Development of Complex Societies in Eastern North America

Evidence for social complexity in Eastern North America appears soon after initial founding populations. Periodic aggregation associated with ceremony, feasting, and increasing evidence for monumentality characterizes the regional archaeological record. These, and other activities such as warfare, were to some extent population dependent. Over time, status became more ascribed and populations increasingly tethered to ancestral places marked with monuments, many with accumulated ancestors. Population movement and interactions are common throughout, tied to environmental changes, warfare, social needs, and the spread of ideologies. Warfare becomes more institutionalized over time in a system of dual organization within both small and large communities.

A Comparison of Mapping Techniques at Chimney Coulee, a Fur Trade Era Métis Settlement

The methods and technologies with which archaeologists map sites have changed significantly over the last few decades, shifting from a compass and chain to total stations and RTK (real time kinematic) positioning systems. In conjunction with the 2013 field season of the Métis Archaeology Project, the authors created a modern digital surface model (DSM) of the site of Chimney Coulee, a fur trade era hivernant Métis settlement near Eastend, Saskatchewan. Métis occupation of the site was concentrated between the destruction of Issac Cowie’s trading post and the later construction of a satellite North-West Mounted Police post. The site was first surveyed and mapped in the late 1980s, but the resulting site maps were limited in scope. This poster will examine the various mapping techniques which have been employed at Chimney Coulee in order to assess the accuracy and efficiency of “traditional” versus
“modern” archaeological surveying methodologies, demonstrating that new techniques allow us to analyze the internal settlement pattern of the site in new ways.

[75] Small Island States for Future Earth  
The populations of small island states constitute some of the most vulnerable communities in the world to the impacts of Global Change. Long-term studies of human-climate-environment relationships in different island theaters around the world provide important information with which to plan modern day capacity building and mitigation. Recent projects by members of GHEA and IHOPE provide the perfect opportunity to cross-regionally compare the thematic lessons that can be learned from these studies of long-term human ecodynamics. In this paper, I will discuss and outline some key messages from these projects that can be distilled in a meaningful way for the Future Earth community. Furthermore, I will outline how multifaceted programs for communication are required to more effectively disseminate these core messages to international decision makers, government departments, non-governmental organizations, and the wider public.

[236] Lithics, Mobility, and Persistent Places  
Lithic assemblage analyses are frequently used to suggest relative mobility of prehistoric hunter-gatherer-forager groups. In this paper we examine several of these measures, including blank-to-core and tool-to-core ratios, richness, and cortex ratio, as well as features of the tool assemblages and their raw materials from several Early Epipaleolithic sites in the Wadi al-Hasa region of Jordan. These include the rockshelters at KPS-75 and Yutil al-Hasa, as well as the open-air site at Tor al-Tareeq. Our discussion examines how we as archaeologists conceptualize terms such as mobility and distance, and we investigate the investment that prehistoric groups had in locale, suggesting that such occupational use is similar to persistent places in later prehistory.

[247] Age-Rank Status of Eastern Pueblo Agriculturalists: A Case Study in Mortuary Treatment from the Albuquerque Basin  
The establishment of an age-rank status social structure amongst various pueblos of the Rio Grande region has been well-documented in the ethnographic literature. However, the antiquity of this social structure and how age-rank status manifested in the mortuary treatment of individuals has not been as thoroughly addressed for the Albuquerque Basin and Lower Jemez River Valley. This research presents data from the Rio Grande Developmental (A.D. 600-1200) and Classic (A.D. 1300-1600). During the Developmental Period, there appears to have been a distinct difference in the types of grave accompaniments interred with individuals under 10 years of age, as well as where these individuals were interred. During the Classic Period, individuals under 10 years of age were almost entirely absent from formal cemetery settings, and appeared predominantly in backfilled rooms and middens. These patterns suggest that an age-rank status social structure was established by the Developmental Period and, although populations transitioned from hamlets to substantial 100+ room pueblos during the Classic Period, this social system remained intact and continued to be represented in the mortuary practices of the Eastern Puebloans.
Cordova, Carlos

[17] **Bridging Disciplines in a Global Context: Environment and Society in Karl Butzer’s Academic Journey**

The study of societal stability and environmental change requires more than just training in geoarchaeological techniques. It requires the ability to bridge the gap between the natural sciences and anthropology. Throughout the decades of his academic life, Professor Karl Butzer has encouraged his students and colleagues to go beyond their expertise and bring the human and culture-related aspects to geoarchaeological research. Trained as a physical geographer, Karl has managed to bridge the gaps between the physical and human branches of geography, and between the geosciences and anthropology. Karl’s academic view has not only focused on theory, but also on methodological approaches to environmental change in a diversity of landscapes, time scales and cultures, ranging from the deep Paleolithic past to recent historic events. Geographically, Karl’s work encompasses research in practically all continents. One important aspect made by Karl is that experience on one part of the world, may help answer questions in another. Why studying Medieval Spain can help understand Colonial Mexico? Why understanding the effects of European pastoralism in Mexico can help understand the effects of European pastoralism in Australia? These are questions of a global nature much needed in geoarchaeology.

[43] **Ritual or War? Burning in the Jornada Mogollon**

What is the significance of room burning within El Paso phase (A.D. 1300-1450) Mogollon pueblos of southwestern New Mexico? Are these events the results of violence, ritual abandonment of rooms, accidental fires or other processes? This poster explores these questions through a case study of Cottonwood Spring Pueblo (LA 175), one of the largest villages in the region. We have identified at least two temporally distinct burning events at the site. This pueblo also straddles a cultural boundary between the Jornada and Mimbres branches of the Mogollon and possesses relatively high frequencies of Salado polychrome ceramics. To contextualize Cottonwood’s burning we will compare it to other pueblos in the region considering their sizes, locations, ceramic assemblages, dates of occupation and numbers of burning episodes.

[64] **Emblematic Identities of the Effigy Mound Manifestation: Symbolic Patterns and Variability in the Late Woodland, Southern Wisconsin**

This presentation reports on results of a study of identity among Effigy Mound peoples in southern Wisconsin during the Late Woodland period. Specifically, investigations of mound form, mound features, biological status, and biological distance are employed to elucidate corporate identity of Effigy Mound societies. Results of this research suggest at least two distinct corporate identities: 1) an overarching identity incorporating similar ritual paraphernalia in the mortuary program across southern Wisconsin and
2) a localized corporate kin-based identity. Local identity was marked by a combination of differential burial dispositions, internal structuring of mound features, exclusion of age classes, and epigenetic structuring among mound groups. There were patterns for the inclusion of geometric and effigy mound forms and certain mound features (including burials) among mound groups and three physiographic regions. Although there was likely an overarching ritual system uniting Effigy Mound peoples, ritual practitioners may have been intentionally interpreting and reinterpreting ritual customs locally; thereby asserting group identity.

[312] *Archaeology among Histories of Terror in the Maya Ixil Region of Guatemala*

Located in the northern part of the Department of El Quiché, the Ixil highland communities of Santa María Nebaj, San Juan Cotzal, and San Gaspar Chajul narrate a long history of resistance. The most recent has been the story of surviving a devastating army campaign against the Ixil indigenous population during the Guatemalan Civil War of the 1980s. Traditional archaeological work was mainly carried out in the Nebaj area and in the Valley of Acul in the 1970-1990s. This presentation addresses the possibilities for conducting a new activist archaeological research in the region, one that links the distant and recent pasts and that is based on recent collaborative agreements with local people, indigenous authorities, academic activists, and members of the Universidad Ixil. San Antonio Titzach is only one of the many archaeological/sacred sites that present the practitioners of archaeology with the opportunity to integrate local narratives, ancient histories, and a community-based project in a collective search for autonomy and legitimization of the Ixil cultural heritage.

[197] *The Development of Hierarchical Societies in the Diquís Delta, Southeastern Costa Rica*

Archaeological research in the Diquís Delta of southeastern Costa Rica has provided information on the emergence of hierarchy through the study of spatial distribution of settlements and different cultural assemblages during the Aguas Buenas (300 B.C–A.D.800) and Chiriquí (A.D. 800-1500) periods. The increase in the site’s size, the presence of sites with mounds surrounded by cobblestone retaining walls, paved areas and accretional stratigraphy, and in some cases with stone spheres, reflects change that can be associated with rank, power and prestige. Possible functions and symbolism associated with hierarchy of stone sphere sets is also explored, taking into account the context in which they have been recorded.

[292] *Household Economy and Exchange among the Classic Period Maya: Recent Findings from the Dos Hombres to Gran Cacao Hinterlands*

This paper draws on multi-scalar archaeological findings to advance a preliminary perspective of the economy of Classic era (A.D. 200-800) from the Dos Hombres to Gran Cacao Archaeology Project located in northwestern Belize. The fieldwork is directed toward large questions of structure and demography, patterns of growth, subsistence and political economy, administration, and social organization. A primary goal of the project is to understand the impact of larger sites, such as La Milpa, Maax Na, and Dos Hombres had on smaller settlements in the Three Rivers region, and in turn to investigate the role that inhabitants and the surrounding hinterlands played in the regional economy. The participation of such sites in the greater regional economy went beyond consumption to coordinating the movement of raw materials and imported finished products to other areas. This paper will present results of a diverse array of field methods and analyses that have generated new data useful for a complex, multi-dimensional view of the project area—by revising estimates of the settlement size and regional context, identifying craft production areas, inter-household interdependence, wealth and social identity, and reconstructing the production and consumption economies of domestic, administrative, and ritual features.

[191] Cultural Dynamics through Rock Art in Eastern Salvador
The East of El Salvador is an area which extends east of the Rio Lempa, in the departments of La Unión, Morazán, Usulutan and San Miguel. In its 7728 km², it has an extremely rich and diversified archaeological heritage. It comprises about 40 rock art sites, which account for almost half of all known sites of this nature nowadays in El Salvador. Archaeological researches that took place in the East have been closely linked to the study of rock art; the first published site in the country was the Cave of Corinto, in Morazán. In 2011, after several investigations initiated in 2004 and carried out in the West and the Center of El Salvador, the Salvadoran/French Archaeological Mission was oriented up to the East of the country. There, those researches revealed concentrations of rock art sites around the shores and the surroundings of the Rio Lempa, in its course to the south, in the northern mountains, and on the slopes of the volcano Conchagua. This legacy of a great variety, including petroglyphs and pictograms. The study of its iconography highlights Mesoamerican and Intermediate Area's influences, confirming that the East of El Salvador was the scene of active cultural exchanges.

[15] Modeling the Prehistory of Regional Interactions in the Moquegua Valley, Southern Peru
The model of cross-cultural interaction that is the focus of this symposium was developed specifically to help model the cultural interactions taking place in the Moquegua Valley of Southern Peru during the culturally dynamic Middle Horizon. In this paper we highlight the flexibility of our model by using it to illustrate how regional interactions changed throughout the prehistoric sequence of this region. The Moquegua drainage is the easiest route from the highlands of the southern Titicaca altiplano to the Pacific Ocean; in addition the middle Moquegua Valley is ideal for large-scale maize agriculture. As a result, regional interactions have been an integral element in this region’s cultural evolution. Starting with the Archaic Period and continuing through the Late Intermediate Period we graphically explore the nature of the regional interactions that took place in each time period and how these interactions shaped the cultural landscape of the Moquegua Valley over time.

Cothren, Jackson (CAST, University of Arkansas) and Jesse Casana (University of Arkansas)
Declassified, Cold War-era satellite images known as CORONA, the codename for the United States’ first intelligence satellite program, offer high-resolution, global stereo imagery dating from 1960-1972. Because CORONA preserves a picture of the landscape prior to much recent development, these images constitute a powerful resource for identification and mapping of archaeological sites and ancient cultural features such as roads, canals and field systems. However, unprocessed CORONA images contain extreme spatial distortions caused by a cross-path panoramic scanning system, and the absence of detailed orientation and camera information makes correction of these errors challenging. This paper presents results of a multi-year effort to develop new, efficient orthorectification methods for KH-4A and KH-4B CORONA imagery, as well as of our distributions system for the imagery through a freely-accessible, online database. The currently available imagery covering the Middle East has begun to transform the ability of researchers to explore the archaeological landscape at regional scales, beyond survey boundaries and across national borders. Our ongoing efforts now aim to make CORONA available in other areas of the globe, including China, South and Central Asia, Eastern Europe, and the African Sahel.

[259] **Boarding Houses and Wage Earning Sisters: The Archaeological Visibility of the Halloran Sisters, Clinton, MA**

The Irish Famines of the 1880s that were largely experienced in the far west resulted in a later rural and coastal immigration. This movement of individuals and families into new communities often established new systems of chain migration and pathways to America. In some cases immigration into small towns, such as Clinton, MA, primarily involved wage earning females and males who lived together in Irish run boarding houses, moving from year to year. How did the family, or some sub-section of the family, change through the Irish Famine, through pulses of immigration, and the relocation of people to America? Historical documentation provides us with a means of tracking relative residential mobility, but it is unclear how or if this might be manifested in archaeological data. Drawing upon the case study of the Halloran sisters in Clinton, MA, between 1900 to 1910, we explore residential patterns that highlight remarkably high levels of residential mobility, co-residency organized around family lines, and paradoxically, the almost total archaeological visibility of the reorganization of the family as a wage earning unit.

[203] **Relational Ties: Residential Burials at Tiwanaku**

The apparent absence of large, spatially segregated cemeteries associated with Tiwanaku’s urban core is one of the clearer, though puzzling, features of its archaeological record. This situation stands in direct contrast to other Tiwanaku Period sites in both the highlands and lowlands where distinct cemeteries have been found. Drawing on recent investigations in the Mollo Kontu sector at the site, we argue that mortuary rituals in the urban core are characterized by the practice of residential burials. Here, the dead were kept nearby as part of everyday life, within families and communities. In addition, the Mollo Kontu area is notable for the high representation of children’s burials. We find that in death children received attention similar to adults; they were remembered and venerated. While mortuary practices have been recognized as important opportunities for the display of wealth and status in many Andean societies, such differences do not appear to have been strongly emphasized in Tiwanaku burials in the urban core. Our data suggest that instead greater value was placed on privacy, intimacy, sentiment and social relations.

[121] **Inka State Canons in Local Communities in the Imperial Heartland (Cusco, Peru)**

Data from the Inka imperial heartland are valuable for discussing the distribution of Inka material culture in provincial contexts. The Cusco region of highland Peru was home to the Inka capital, and archaeological data from local sites offer evidence of the development of state aesthetic canons, as well as how distribution patterns reflect continuity and change in local communities and settlement systems. The scope and intensity of Inka material culture distributions in the capital region permit robust comparisons with provincial sites, allowing a deeper consideration of Inka imperial administrative strategies. This paper will discuss the material manifestation of Inka state canons in the Cusco region, and how regional patterning can be used to develop problem-based excavation programs. We then present aspects of our excavation work at three sites with Inka occupations: Pukara Pantillijlla, Ak’awillay, and Cheqoq. These sites represent only a subset of the ecological and social variation in the Cusco region from the time of early Inka expansion to the European invasion, but they illustrate some of the different local manifestations of state canons at communities whose fortunes waxed and waned under Inka rule.

[168] **Bodily Discipline and Healthcare in a Mining Boomtown: Archaeology of St. Mary’s Hospital in Virginia City, Nevada.**

St. Mary’s Hospital in Virginia City, Nevada, was operated from 1876 to 1897 by the Daughters of Charity
of St. Vincent de Paul, a Catholic organization founded in France. Built environment and archaeological excavations at the hospital site reveal the organization’s efforts to bring modern healthcare practices to the miners and settlers of this western boomtown. Drawing upon theoretical frameworks from Marx, Foucault and Bourdieu, the authors observe that patients and staff at the hospital also experienced bodily discipline, particularly through landscaping, architecture, and items related to healthcare. Bodily discipline reinforced ideologies and daily practices of reform, purity and service, which leveraged healthcare practices. Such practices and ideals were also in keeping with western notions of progress.

Cox, Kim and Carolyn Boyd (SHUMLA)
[199]  Breaking the Color Code in Pecos River Style Rock Art: Why It Is so Important
The polychrome rock art of the Pecos River style contains four basic colors: red, black, yellow and white. The same four colors are part of an Archaic Mesoamerican core iconographic system that assigns these specific colors to the cardinal directions. Because of this, they have also adopted implied meanings that have persisted in belief system from some ill-defined Archaic time often up until historical times. The Pecos River style rock art fits squarely into that Mesoamerican iconographic continuum, having many of both the simple and complex meanings that have persisted in Mesoamerican cultures for millennia. In our study of the rock art, we have recognized that nothing in the art panels is random. This basic rule applies to the colors. Understanding their meanings gives invaluable insight into understanding the panels.

Coyle, Philip (Western Carolina University)
[339]  Politics of the Plaza: Conceptual Metaphors of Legitimacy among the Náyari and other Central Uto-Aztecan Peoples
The indigenous groups of the Sierra Madre mountains of west Mexico are the probable living descendants of the archaeologically and ethnohistorically known Azteatlán civilizations, and the ceremonialism of these contemporary people provides insights for the interpretation of those earlier civilizations. Specifically, the patio-based ceremonialism of the Náyari (Cora) and other Central Uto-Aztecan peoples is a basic conceptual metaphor that may be used to help understand earlier plaza-based ceremonialism. The east-west and axis mundi orientation of these plazas--such as underlies Central Uto-Aztecan deer-hunting ceremonialism-- is closely tied to synechdochical and hierarchical tropes that can be used by political authorities to legitimate their positions within a Flower World religious ideology. In the Náyari language these tropes are signaled by the directional term námiche. Given Mathiowetz’ recent arguments concerning the importance of Paquimé in extending this politically potent cosmology into the American Southwest, it seems likely that such symbolic tropes might also be aspects of the conceptual metaphors that he discusses.

[289]  The Development of Social Groups, Leadership and Inequality in the Central Mesa Verde
In this paper we explore how population growth and resource depletion in the Central Mesa Verde landscape between AD 600 and AD 1280 set the stage for territorial conflict, and how lineage and clan membership likely affected the structure of coalitions. We take a three-pronged approach in which we combine models for the evolution of leadership, models for the formation of coalitions and alliances, and models for conflict and warfare. In these models individuals eschew autonomy and join groups when outside pressures for resources are sufficiently great that being a member of a group would be beneficial for individual survival and resource acquisition. Individuals in groups, and groups in coalitions, contribute to a “public good” via defense of corporate resources; defection may be punished. These are layered onto an agent-based modeling framework within the Village Ecodynamics Project. We are able to compare output from the simulation to the archaeological record to understand how the structure of corporate kin group leadership could lead to the development of more hierarchical structures and how conflict, or the threat of conflict, could influence the size of and leadership in groups.

Craig, Douglas (Northland Research) and Brent Kober (Northland Research)
Multi-Household Social Units, Property Rights, and Wealth in Hohokam Society

Recent discussions of Hohokam sociopolitical organization have focused on household-level and community-level social units. Far less attention has been paid to the social units that operated at an intermediate level between the household and the community. In the case of the Hohokam, these intermediate social units are generally expressed in the form of multi-household residential groups that have been variously called village segments, habitation areas, or residential districts. We examine the role of these intermediate social units in Hohokam society, particularly their role in acquiring and transmitting property. Their role in promoting and suppressing social inequality is also discussed.

A Diachronic Perspective on Variation in Lithic Procurement at Housepit 54, Bridge River Site, British Columbia

The Bridge River settlement in the Middle Fraser River Canyon of British Columbia had an economic base emphasizing procurement of salmon, deer, geophytes, and berries. Changes in the environment after ca. 1300 cal. B.P. appear to have affected subsistence returns as salmon numbers likely declined and search costs for ungulates increased. Current excavations by Dr. Anna Prentiss at Bridge River (EeRI4) Housepit 54 focus on an estimated 15 occupation floors dating in the range of 1000 to 1500 cal. B.P. This allows for a unique study of inter-generational adaptations. This poster presents a study of variability over time in lithic raw material use by Housepit 54 residents. Investigation of artifacts recovered from each floor compared to faunal data will increase understanding of the relationship between use of lithic sources and shifts in subsistence practices.

GoPro or Go Home: GIS Modelling and Experiential Ground Survey of Past Travel Routes in Saglek Bay, Labrador

This paper discusses the results of an archaeological survey of the cultural landscape at North Arm in Saglek Bay, Labrador. The aim of the project is to combine two methodological approaches, GIS and experiential field walking, to gather data on Inuit trail use. Trails are important features of human occupation of the landscape and play an essential role in travel, migration, kinship relations and in a group’s relationship with their environment. Trails serve everyday purposes but also have an ideological element which bears on the way people thought about and constructed the landscape. The importance of movement is reflected in Inuit material culture with technologies such as the kayak and komatik (sled) used to facilitate travel. This study utilizes the View-Shed and Least Cost Path (LCP) functions of GIS in order to predict inter-visibility and movement between and within archaeological sites. These predictions are informed by a ground survey focusing on gathering experiential landscape data captured using a head-mounted wide angle visual recording device (GoPro) and spatial data using a GPS device. This methodology was used to explore potential routes and trails in the past, focusing as much on spaces between features as the features themselves.

Inscribed, Embedded and Embodied: Envisioning a Bioarchaeology of Inequality, Vulnerability and Pain

A hallmark of modern bioarchaeology is its commitment to a holistic theoretical approach. The biocultural synthesis has indelibly shaped bioarchaeological research and has challenged scholars to reconsider the upstream causes of health disparities, and to situate mortality and morbidity data within broader social and political contexts. Integrating archaeological, ethnographic and biological data, bioarchaeologists have documented disparities in survival and functional quality of life by examining the ways that ancient bodies are literally and figuratively pained. Using the lens of agency and embodiment affords theorizing about the body, power and culture. Case studies from the Greater Southwest are provided that demonstrate the ways that ritualized acts of child sacrifice and female captivity are inscribed on the body and written on the bones. Embodiment theory provides a way of linking culturally sanctioned violence and long term morbidity with broader patterns of social integration (and in some cases, fragmentation). This overview sets the stage for the studies in this session and illustrates the ways a social bioarchaeology of inequality can link empirical data derived from skeletal remains with the larger cultural
processes that institutionalize and normalize suffering and inequality.

Analyzing 18th-Century Catawba Pottery and a Lead Glazed Sherd Using Portable X-Ray Fluorescence (pXRF)

Recent research has demonstrated that Catawba ceramic practices changed abruptly and dramatically after 1759 following a devastating epidemic. Pottery from historically documented Catawba towns indicate potters adopted new techniques and styles as they adjusted to new economic and social conditions, including copying European vessel forms, experimenting with new ceramic paste recipes, and utilizing new decorative motifs. The discovery of a lead-glazed sherd on what otherwise appears to be a Catawba pale-colored paste suggests Catawba potters may have also experimented with wholly new ceramic technologies. This poster presents the results of a compositional study of Catawba and non-Catawba pale-bodied colonowares from South Carolina and Virginia to determine if this glazed sherd is of Catawba manufacture using pXRF and multivariate statistical techniques.

Revisiting Experimental Jade Polishing: Replication and Investigation on Ancient Maya Techniques

Old and New World ethnographic and ethnohistoric accounts of jade polishing techniques document the use of leather, wood, bamboo, emery, slate, and other stones as polishing tools. Archaeological evidence from Maya sites indicates that limestone likely functioned as polishers in jade production. In 2013 the authors presented a poster documenting results from initial experimental replication of jade polishing with limestone, slate, hematite, and leather. We concluded that all four materials produced some marked changes on the surface of jade beads. This paper aims to discuss the original results of this experiment, and new data from polishing using previously tested materials and additional ethnographically documented materials.

Crawford, George (Blackwater Draw National Historic Landmark)

The Clovis Site: Synthesizing a Legacy

Over eighty years of research has occurred at the Clovis site. Due to some unfortunate circumstances, there has not been a possibility of an over-arching, synthetic look at the assemblage in its entirety until recently. This had led to some wildly inaccurate information and assumptions about Blackwater Locality 1. In the last five years, an analysis of all available materials collected at Blackwater have been examined and analyzed. This poster is not an attempt to answer all the possible questions there may be concerning Paleoindians at Clovis, but to give a glimpse at the current and future research at a remarkable site.

Changing Complexity in the Norte Chico, 3000-1800 B.C.E.

Monumental construction flourished in the Norte Chico region of Peru starting around 3000 B.C.E., based on flourishing cultivation inland, fishing on the coast and active regional exchange of plant and marine products. The monuments and associated buildings and activities reflected the emergence of two interconnected bases of power: economic and ideological. Economic power grew from irrigation-based agriculture and provided a means for Norte Chico leaders to gain the compliance of the Norte Chico population. This economic base was supported and reinforced by a standardized religious ceremonial context focused on large and small scale public architecture. The positive and negative incentives of access to (or denial of) irrigation water and agricultural products proved an effective way to recruit and direct a significant labor force. Rather than serving to self-aggrandize or glorify individual rulers, however, labor was focused almost exclusively on the construction of large-scale religious architecture. Physical coercive power manifested in some kind of military was absent. The full state triad of economic, ideological, and physical power did not emerge until the subsequent Initial Period.

[66] Changing Social Contexts of Mimbres Ceramic Production and Distribution

In early Mimbres-area research, pottery was the primary impetus for excavations in terms of acquiring museum collections and temporal control. In a major improvement in method and theory, the Mimbres Foundation focused on finer chronological control and analysis of pottery designs. More recently, compositional analysis of thousands of samples, including some 1000 whole Mimbres vessels permits a more refined assessment of design relative to both production locale and location of last use. Hypotheses regarding such issues as emphasis on depiction certain classes of animal by potters in specific villages can now be tested with greater confidence. During the Classic Period, in general, there was substantial and broad similarity in the designs on the painted pottery, regardless of production locale. Possible explanations for the patterns are explored.

Creese, John (University of Cambridge)

[338] Indigenous “Economies of Affect” in the Northeast Woodlands

This paper considers the sources of demand for European-manufactured goods among the Native American societies of the Northeast Woodlands in the early seventeenth century. I propose that among the Wendat-Tionnantate and Attiwandaron societies of southern Ontario, objects perceived to be potent – including many obtained from European sources – fed into local ‘economies of affect’. These systems involved characteristic cycles of ritual exchange focused on the accumulation and enchainment of bodies and belongings. Their social efficacy depended on ‘emotion-work’ accomplished by the iterative bundling and fragmentation of highly affective, inalienable objects. Exchange with Europeans, however, required that alienable objects obtained in trade be materially transformed into inalienable ones appropriate to the demands of this ‘economy of affect’. Certain media, such as wampum and glass beads, were particularly suited to accomplishing this transformation, and were therefore crucial ‘switchers’ that linked local and global economies in the early seventeenth-century Northeast.

[187] Simulating Isolation by Distance in Space and Time

This paper explores the robustness of phylogenetic methods for detecting variations in branching and blending signals in the archaeological record. Both processes can generate a spatial structure whereby cultural similarity between different sites decays with increasing spatial distance. By generating a series of artificial records through the controlled and parameterized environment of an agent-based simulation, I will: a) illustrate the weaknesses and the strengths of different analytical techniques (distogram, Mantel test, Retention Index, and Delta Score); b) determine whether they are capable of assessing how spatial isolation determine cultural diversity; c) and establish whether they can detect variations in the nature of horizontal transmission over time. Results suggest that variables other than the spatial range of interaction (e.g., the frequency of fission events, population dynamics, and rates of cultural innovation) have different effects on the output of some phylogenetic analyses. The cultural descent and interaction of ceramic tradition in Neolithic Europe is then evaluated taking in consideration the results of the simulation exercise.

Crews, Christopher (Texas A&M University)

[7] Cultural Changes in the Piedra Lumbre Valley, NM during the Developmental-Coalition Transition

The excavation of Bull Canyon II revealed a change in cultural occupation and land use in the Piedra Lumbre Valley. Around 1000 BP, a technological shift is evident through thermal features, lithic raw material, and ground stone technology. The purpose of this paper is to show that the early occupants of the site of Bull Canyon II were highly mobile hunter-gatherers focused on formal hearth features, wild plant foods, and resharpening of obsidian tools, while the later inhabitants were logistical groups utilizing the area for wild resources such as pine nuts and other wild plants and animals. This is evidenced by a shift from formalized, slab-lined, bowl-shaped hearths to informal open burns without any support. Furthermore, the use of obsidian is higher earlier and wanes, while the use of Pedernal Chert (the nearest source of lithic material) increases.

[140] Experimentation in Ceramic Decorative Technology: The Central Mexican Multi-Prong Brush
The Central Mexican pottery type known commonly as Mazapan Wavy Line is a red painted pottery notable in the northern area of the Basin of Mexico and Tula at the earliest part of the Early Postclassic period (ca. 900 AD). Stylistic and compositional variability of this diagnostic pottery suggests that production occurred at multiple locations across the region. However, the specific technologies and techniques for producing the distinctive multiple-line motifs are not well understood. In this interdisciplinary collaboration, we present our initial efforts in exploring the technological challenges in replicating this unique decorative tradition. Consideration of natural materials readily available in Central Mexico formed the framework for developing brush prototypes for experimentation. Each successive step of investigation provided understanding of the unique attributes required of bristle type and length, interaction with clay and paint, and the challenges in maintaining separate and clearly defined lines within the resulting designs. The difficulties in reproducing exactly the stylistic attributes observed in the archaeological sample of Mazapan Wavy Line pottery suggests the importance of training and learning communities in the production of this pottery type. We present our successes and failures in experimentation and suggestions for further inquiry.

Climate Change Archaeology in the Southern North Sea Basin

The North Sea basin witnessed enormous climate and environmental changes during the Pleistocene-Holocene transition caused by glacial meltwater outbursts and sea level rise. Multi-proxy paleoenvironmental and archaeological evidence indicates a remarkable variability of responses of ecosystems and human societies to climate change in this region. This evidence forces us to move beyond deterministic approaches to climate-ecosystem-human interaction toward a greater understanding of the variable impacts of climate change on ecosystems and hunter-gatherer societies across different spatial scales. In this presentation we focus on three abrupt climate change events between 13,300 and 8,200 years ago. We present evidence for the impact of paleolake drought on Late Glacial Federmesser social organization during the GI-1b event and the development of new Mesolithic sociocultural networks between the 9.3 and 8.2 events. The North Sea basin currently faces some of the same threats caused by climate change, particularly sea level rise. This presentation sets up a climate change archaeology framework for the region that focuses on the variable resilience and vulnerability of ecosystems and human societies to climate change throughout the Holocene period.

Obsidian and Wari Expansion: A View from the Vitor Valley of Southern Peru

For the past five years, one of the primary goals of the Vitor Archaeological Project has been defining the nature of the Wari presence in the Vitor valley of southern Peru. Here we present the results of geochemical sourcing undertaken on obsidian recovered from the Millo site complex using portable x-ray fluorescence (pXRF) technology. Using this new source data in tandem with a regional contextualization of Millo’s obsidian assemblage, we argue that the intrusive Wari presence in Vitor is more complicated than previously thought. Earlier interpretations of the Millo sites cast them as installations of state infrastructure established to interact with mobile, non-Wari populations. Both our source data and point forms, however, show great consistency with other Wari colonial enclaves and nearby Wari-influenced groups, suggesting that no exchange of obsidian took place in Vitor between the Wari population and groups culturally outside of the Wari sphere. It remains likely, however, that the Millo complex was constructed to serve some transportation-related purposes. Considering the similarity of our assemblage to those found at Wari sites in Moquegua, we argue that the Wari installations in the Vitor valley were intended to consolidate caravan routes between this far-flung colony and the Wari heartland.

Crook, Wilson, Michael Collins (The Gault School of Archaeological Research), Clark Wernecke (The Gault School of Archaeological Research), Robert Lassen (The Gault School of Archaeological Research) and Sergio Ayala (The Gault School of Archaeological Research)

Synopsis of the Prehistoric Occupations at the Gault Site (41BL323), Bell County, Texas

Every known interval in the prehistoric record of Central Texas is represented at the Gault site (41BL323), from Older-than-Clovis through Paleoindian, Archaic, and Late Prehistoric. Years of systematic looting at the site has disrupted the integrity of much of the Holocene deposits (Archaic to Late Prehistoric) over a large part of the site, however the deeper horizons, notably Clovis and below, remain undisturbed. As such, the site represents a record of virtual continual occupation over the past 14,000+ years. Thus the unique, prolific environment of Gault continued to meet human needs in spite of wide swings in climate. Moreover, the locality supported a variety of different hunter-gatherers/foragers with neither specialized big game hunting nor adoption of horticulture indicated. In large measure, this record is attributable to abundant chert of high quality, reliable springs, and a diverse biota. Plant and animal communities long adapted to the highly variable climate of the region meant that no matter the conditions, an adequate subset of the biota produced sufficient subsistence resources.

Life and Death of a Horse from Roman London: Skeletal Analysis with a Consideration of Pathology Patterning and Activity-related Skeletal Markers

Much of zooarchaeology deals with large assemblages of bone fragments, which has led to the use of sampling methods and an emphasis on statistically-based analysis. However, it has long been
recognized that this method may miss significant data, particularly when partial or whole skeletons are part of the assemblage. Applying human-burial analytical methods, creating osteo-biographies, of animal burials can inform us about important aspects of the animal, its environment and its relationship with human society. This type of analysis is particularly important when investigating horse depositions which typically make up very small percentages of faunal assemblages. This presentation investigates the burial of a single horse from Roman London. The individual is reconstructed using osteological and anatomical/artistic methods coupled with a historical perspective. Particular attention will be paid to evidence and evaluation of pathology and its possible relationship with activities in the living animal such as riding, driving or use as a pack horse.

Cross, John (Bowdoin College)

[292] Actions and Strategies: The View from a Lithic Workshop at Kichpanha, Belize
Recent research on market economies among the ancient Maya provides an analytical point of entry for archaeologists to explore human actions at local and regional scales. While long-term trends in artifact form and technology, settlement size, or architecture may be identified over broad geographic areas, ultimately the archaeological record is created by people living their lives within a specific historical and social context. Markets (or alternative ways in which households might gain access to goods) occupy the intersection of action and strategy at the levels of the individual, household, community, and region. Excavations at a Late Preclassic lithic workshop at Kichpanha in northern Belize show evidence not only for the production of chert tools, but also for their maintenance and replacement. Inter- and intra-site comparisons between workshop lithic assemblages and with those from residential contexts suggest differences among households that may be linked to tool production either by specialists or by non-specialists and to the possible presence of markets. Access to finished tools or to the skills of a specialist is neither universal nor automatic across a settlement or a region, but is constantly being negotiated by human actors who are responding to their circumstances and to perceived opportunities.

Crothers, George (University of Kentucky)

[74] The Cave Research Foundation Archaeological Project and the Eastern Agricultural Complex
In 1963, Patty Jo Watson began systematically recording archaeological remains in the extensive, dry passages of Salts Cave, Mammoth Cave National Park, Kentucky. This was an official project of the recently organized Cave Research Foundation, a multidisciplinary group of cave explorers and scientists interested in caves and karst environments. With the expertise and logistical support of CRF, Watson—a specialist in Near Eastern prehistory—initiated an interdisciplinary scientific research project in Salts Cave. A central focus of the CRF Archaeological Project for Watson and collaborator Richard A. Yarnell was the relationship between indigenous squashes and gourds—abundantly present and beautifully preserved in the dry passages of Salts Cave—to their presumed Mesoamerican antecedents. The CRF Archaeological Project refocused interest on the Eastern Agricultural Complex, and helped establish Eastern North America as one of the few world regions where an independent, indigenous, prehistoric agricultural system was created.

[243] Power, Production, and Practice within Communities of Potters in the American Southwest
Among populations in the American Southwest, children participated in the division of labor as household members. They had everyday access to potters within a community of practice. The paths to full participation in potting practice are documented in historical records and autobiographies, and these paths are largely, but not entirely, reflected in the prehispanic vessels. Archaeological assemblages reveal that participation in communities of southwestern potters varied over time and across space. Variation in the sequences of mastery reveals important differences in access to resources needed for learning that suggest changes in relations of power within communities of practice, particularly among potters producing polychrome ceramics after A.D. 1250. Shifts in the organization of production, use of
pottery in ritual activities, and the importance of pottery in signaling political alliances may have contributed to differential control over materials and knowledge. Understanding how and why potters might have restricted participation in communities of practice provides insight into power relations and secrecy in the late prehispanic Southwest.

Crumley, Carole

Continental Europe

The Roman Empire is one of history's great successes, as well as a spectacular failure. There are many parallels with societies today. Key elements are: reliance on a handful of vulnerable staples and on unstable or diminishing resources, climate change that affects resources and the ability to respond to problems, sustainability undermined by increased social complexity and the cost of solving problems, diminishing state income (trade and taxation), increasing expenditures (wars, rebellions), and failure to invest in infrastructure and its maintenance. Multiple shocks and system-wide impacts beyond initial sources of instability can render great societies vulnerable.

Making the Past Relevant: Finding Solutions to the Challenges of Heritage Preservation in Rural Communities in Peru

In the impoverished traditional Quechua communities of rural Ancash, Peru, the planning and implementing of heritage preservation projects faces a variety of obstacles that require creative solutions. With little government oversight to enforce protection laws, the monumental archaeological sites of Hualcayan and Pariamarca in the Cordillera Blanca mountain range are poorly preserved. The challenge of conflicting interests among villagers-such as the need to increase agricultural yields-combined with a loss of connection to the ancient past, has led the US and Peruvian collaborators of the Proyecto de Investigación Arqueológica Regional Ancash (PIARA) to engage local communities and municipalities in developing a multi-faceted approach to promote and protect their cultural heritage. The engagement includes: 1) education-focused heritage enrichment projects with local school children and their teachers, 2) the design of local museums that will double as community centers, and 3) the integration of these heritage centers into an already present adventure tourism circuit, where visitors can explore the area's natural, cultural, and archaeological resources in addition to trekking into the famous Parque Nacional Huascarán. The latter project will connect the two sites as tourism destinations with homestays in local villages rather than a simple pass through on a Cordillera trek.

Cruz-Morales, Christian (Eastern New Mexico University)

Correlation of Death Rate and Periodontal Disease in the Prehistoric Human Remains of Pueblo Bonito

Periodontal disease is an oral infection caused by 500 different bacteria that invade the mouth. The development of this disease depends on several factors such as inheritance, environment, diet, and dental care. Recently, scientists have proposed a correlation between cardiovascular and periodontal diseases as a cause of serious health problems in modern humans. This premise has provoked a debate among health experts who are not completely convinced of such correlation. This study focuses on the severity of periodontal disease in dental remains of the Ancestral Puebloans who inhabited Pueblo Bonito in Chaco Canyon, New Mexico, from A.D. 850-1140. The harsh climatic conditions of Chaco Canyon and the high consumption of maize by the Ancestral Puebloans would have favored the factors that cause periodontal disease. This research study tests the correlation of the severity of periodontal disease and the age at death of the prehistoric people of Pueblo Bonito. The findings of this study also provide a perspective on the human past concerning periodontal disease and its correlations with other health problems in modern humans.

Cucina, Andrea (Universidad Autonoma de Yucatan) and Vera Tiesler (Universidad Autonoma de Yucatan)
Population Dynamics during the Classic and Postclassic Period Maya in the Northern Maya Lowlands: The Analysis of Dental Morphological Traits

This study focuses on population variability and morphological affinities among the Classic and Postclassic period Maya (A.D. 250-1521) of the Yucatán peninsula. To this end, the dental morphological traits of eighteen dental collections from the Northern Maya Lowlands was scored, following the ASUDAS standard. Intra-site variability was calculated using seventy-nine dichotomized traits, while patterns of morphological affinities were calculated using thirty-six variables. Cluster Analyses -UPGMA and Ward grouping methods- Principal Components and Maximum Likelihood were also elaborated and tested with bootstrap. Our regional survey indicates general homogeneity among site populations, materializing long-standing population movement and exchange across the Yucatecan territories. Unsurprisingly, intra-site variability reveals higher biological variation among the urban populations under study and among coastal dwellers, which we presume to have been involved in trading. Morphological affinities, in turn, show a pattern of similarity among sites involved in the inland corridor that connects the Northern Peten to the Northern Maya Lowlands during the Classic. On the contrary, the Postclassic site populations, although not entirely separated from their Classic descendants (revealing to some extent biological continuity through time), do not seem to follow geographical patterns but instead distribute more randomly than the earlier dental series.

The Segesser Hide Paintings: Explorations in Ethnohistory and Archaeology

Since the Museum of New Mexico acquired the Segesser Hide Paintings in 1989, they have generated considerable interest among scholars from anthropology, history, and art. The depictions are rare glimpses of Europeans and Native Americans engaged in battle on the Great Plains of North America, wordless narratives of the dynamics of militaristic interactions which influenced alliances and empire in the colonial period. Deciphering the events depicted on the hide paintings has traditionally incorporated scholarship in the fields of ethnohistory as well as art history. Archaeological evidence of colonial military expeditions across the Great Plains may provide an alternative avenue of interpretation.

Culleton, Brendan (The Pennsylvania State University) and Douglas Kennett (The Pennsylvania State University)

Developments in Radiocarbon and Stable Isotope Preparation of Archaeological Materials at the Penn State Human Paleoecology and Isotope Geochemistry Lab

The Human Paleoecology and Isotope Geochemistry Lab at Penn State was established in 2012 with the dual purpose of providing research and educational opportunities in archaeological sciences for faculty and students in the Department of Anthropology. The lab articulates with the Keck Carbon Cycles AMS Facility for high-precision \(^{14}\)C dating of organics, carbonates and bone, and integrates sample quality control through EA and IRMS at the PSU Light Isotope Lab for elemental and stable isotope analysis. Sample processing protocols for archaeological materials are continuously developed and refined, including small-sample preparation (e.g., single seeds, and leaves for AMS), alpha-cellulose extraction for wood, ultrafiltration and modified XAD-purification for bone samples, and Fourier-Transform Infrared Spectroscopy for QA on cremated bones. AMS and stable isotope projects currently span the last 20,000 years in the Americas, Europe, and the Near East.

Children's Activities and the Context of Learning of Skills: Using HRAF's Ethnographic Database to Inform on Spatial Recognition of Learning Activities in the Archaeological Record

eHRAF World Cultures, an online database produced by Human Relations Area Files, contains a plethora of ethnographic descriptions including references to children’s activities and transmission of knowledge. This study employs the eHRAF World Cultures database and the subjects from the Outline of Cultural Materials (OCM) including “games,” “transmission of skills,” “ceramic technology” and “settlement patterns.” A sample of ethnographies was examined for information related to children’s activities. In particular, the study focused on the spatial, social and environmental context of learning behavior as well
as the morphology of children’s learning devices or “toys.” The compiled dataset includes information on
the age and gender of the children, type of activities, morphology and types of learning materials as well
as data concerning environmental, spatial, social and material context. This paper addresses how these
ethnographic examples might assist archaeologists in recognizing patterns of material culture and spatial
context of children’s activities and social behavior in the archaeological record.

Cunnar, Geoffrey (WCRM)

[115] Applying Gumbrecht’s Concept of Latency to Understanding our Non-understanding of
the Archaeological Signature of the Child’s “World” at Prehistoric Camp Sites in the Great
Basin

The archaeological record in the Great Basin is rich and spans the Protohistoric to the late Pleistocene. In
contrast to European studies in the last 25 years, there is a pronounced lack of attention to the
archaeological record of children in North America. We have only begun to address questions concerning
socialization and nurturing of children, especially as they pertain to learning behavior. In this paper, I
incorporate Gumbrecht’s concept of latency to frame the discussion of seeing the unseen or the latent
presence in regards to the interpretation of prehistoric children. Traditionally the focus has been on the
identification of projectile point types and adult activity areas while often relegating much of the
assemblage to indecipherable palimpsests. While we might recognize that children were present and that
their material signature is a component of the archaeological record, the latent nature of the phenomenon
coupled with a predominately surface record can be frustrating and may lead to ignoring the presence of
children. I will use examples from the Great Basin to argue that evidence for the careful nurturing and
teaching of children can be teased out of the archaeological record, if we incorporate looking for
appropriate technological and spatial signatures.

[118] The Ritual Mode of Production in the Casas Grandes Regional System

In this paper, I explore whether Paquimé’s emergence as a regional center at around A.D. 1350 reflects
the development of what Speilmann (2002) has described as a “Ritual Mode of Production” in the Casas
Grandes Region. Drawing analogues from the heterogeneity of modern capitalism and recent finding of
the Chihuahua Archaeology Project, I hypothesize that this mode was inconsistently developed across
the wider Chihuahua culture area depending on local productive opportunities. To illustrate my case, I
discuss the results of recent work on southeastern edge of the Casas Grandes Regional System by the
Santa Clara Archaeology Project. Surveys, GPR assessments and test excavations show that
settlements are continuously occupied during the Viejo and Medio Periods and lead to the emergence of
a ballcourt and regional settlement cluster.

[113] Trade Winds: Animal Use and Exchange at the Ancient Maya Sites of Marco Gonzalez and San
Pedro, Belize

Faunal remains from coastal sites can provide unique insights into the economic and socio-political
relationships between island and mainland polities and between mainland polities themselves. A
preliminary examination of remains recovered from the Maya sites of Marco Gonzalez and San Pedro on
Ambergris Caye, Belize, reveals that marine resources provided a range of products from foods to tools
to jewelry and tomb or burial furniture. At Marco Gonzalez in the Late to Terminal Classic period, and San
Pedro in the later Postclassic, the discovery of rich assemblages of imported ceramics and other artifacts
indicate that the caye and its settlements served as important trading ports, with strong ties to Lamanai
and other mainland sites from Honduras to the Gulf Coast. Archaeological excavations at both sites have
revealed heavy exploitation of marine resources, including mollusks, fish, marine turtles and marine
mammals, whose various products were a valued trading commodity locally and on the mainland. The
possible use of non-local species and unusual element distributions provide information on daily
practices that linked the island with mainland sites. These patterns are compared to other coastal/island
assemblages in the Maya region where such trade interactions have been hypothesized but not fully
explored.

Cohonina Forts and Line-of-sight Networks

Cohonina forts have been the focus of a long, if less than intense, debate in northern Arizona archaeology since the 1940s. The debate centers on the functional nature of these topographically elevated, thick-walled, masonry structures. Some consider them defensive, while others regard them as socially integrative signaling stations linking dispersed social groups. If these were integrative structures that functioned as nodes in a communication network linking Cohonina communities via lines-of-sight, they could provide important insight into the structure of Cohonina social organization at both the intra- and inter-community levels. I report the results of new survey around the Pittsburg Fort north of Williams, Arizona and a subsequent GIS-based viewshed analysis. The data from this project suggest the Pittsburg Fort was ideally positioned to maintain lines-of-sight with a series of other Cohonina integrative facilities in the surrounding landscape. Using these data, I discuss ways to integrate settlement systems analyses into a landscape archaeology perspective capable of developing tests that rigorously demonstrate intentionality and meaning in line-of-sight networks on the part of prehistoric agents. I then discuss the implications that Cohonina communication networks have on our understanding of social organization and regional interaction in the Southwest.

The Life and Times of Lorazan Asisara: An Analysis of Mission Demographics in Comparison to the Testimony of a Santa Cruz Indian

Lorazan Asisara was one of a handful of Native Californians to give an account of the California Franciscan Mission system. As such his words, like those of the few other Native Californians to testify, are given a great deal of weight. This paper compares a number of Asisara’s statements to demographic data derived from California Mission records to better understand how reflective Asisara’s statements are to the broader conditions of Native Californian mission life. In doing so, Asisara’s statements are taken as being truthful, but also needing contextualization based on his specific position within Mission Santa Cruz. In light of this, Asisara’s position within this mission’s hierarchy is examined to better understand his views on Native Californian mission life; including relations between Franciscan friars and Native Californians, the attitudes of both towards each other, and Asisara’s recounting of pre-colonial Native California lifeways. Besides these considerations, the key foci of this paper are Asisara’s recounting of violence and punishment repertories, missionary recruitment practices, the internal and external social networks of Mission Santa Cruz Native Californians, mission social hierarchies, and events during the closing days of Mission Santa Cruz.

Behind Walls: Cerro Chepén and San Ildefonso, Two Fortified Settlements in the Jequetepeque Valley

Cerro Chepen and San Ildefonso are two fortified prehispanic settlements that illustrate the antagonistic relations between the small political formations that coexisted in the Jequetepeque valley during Late Mochica. Since 2009, the San Jose de Moro Archaeological Program has focused on the study of these sites in an attempt to establish their complex occupational histories, which include the Middle and Late Moche, Moche V, Transitional, Wari, Nieverfa, Cajamarca and Lambayeque presence and their relations with other sites in the Jequetepeque Valley, particularly San Jose de Moro and Huaca Colorada. In tandem, these sites describe the complex process that led to the abandonment of practices associated with the Mochica society, the incremental endemic war between the Jequetepeque Mochicas and the appearance of the Transitional period that entails the transit and origin of the Lambayeque society. In this line, this study has combined a series of multidisciplinary strands that include topographical maps, 3D architectonic reconstructions, 3D modeling through photogrammetry and the systematic study of artifacts and botanical remains.

Continuity and Change in Late Intermediate Period Households on the North Coast of Peru

After the collapse of Moche society around A.D. 800, household life continued in coastal valleys of
northern Peru, and in many ways remained much the same as it had been in previous centuries. As it had been under the Moche, daily life in the Late Intermediate Period (A.D. 900-1450) was likely intensely local, based on the rhythms of irrigation agriculture, extended family and community dynamics, and local ritual cycles. Late Intermediate Period households, however, were confronted with new sociopolitical configurations and economic institutions at valley-wide and regional levels. In the Lambayeque/La Leche Valleys, households weathered the relatively rapid coalescence and collapse of the Middle Sicán state at Batán Grande, while households throughout the north coast were faced with conquest and control at the hands of the expansive Chimú empire. This paper summarizes what we know about continuity and change in Late Intermediate Period households and draws on my own research in the Jequetepeque Valley to explore how post-Moche household life responded to new demands and opportunities at a regional scale.

Pyro-Lithics: Experiments from Koobi Fora 2013

Identifying fire in paleo-archaeological studies is contentious. Compared to lithic artifacts or faunal remains, remains of fire, especially from Plio- and Pleistocene periods, may be difficult to identify as fires are ephemeral and the physical traces may degrade over time or become essentially non-existent. To aid in better understanding archaeological remains of fire, research from the 2013 field season at Koobi Fora systematically tested lithic changes via direct thermal alteration. Experiments were undertaken to record effects of fire on materials found in the archaeological record as well as the sedimentary contexts in which we find sites, to be used as a reference collection for comparison to the archaeological record.

The Role of Geoarchaeology in an Interdisciplinary Examination of Tree Island Sites, South Florida Water Management District and Everglades National Park, Florida

The inclusion of Section 106 compliance in the NEPA review process has increased the need for cultural resource managers to develop mitigation programs that incorporate disciplines outside conventional CRM. Oftentimes, however, these multidisciplinary investigations are conducted independent of one another and at separate phases of the mitigation process. Not only does this lead to a redundancy in field time and sample collection, but also to a research environment where interrelated data are examined in a vacuum. This has the adverse effect of making multidisciplinary approaches cost-prohibitive while limiting the interpretive power that makes collective research so invaluable. Highlighting the importance of an integrated research strategy to the development of a cost-effective multidisciplinary cultural resource survey, this paper presents the results of a combined geoarchaeological, archaeological, and ecological investigation of tree island sites in the Florida Everglades. The project goals focused on assessing the effect future water-level fluctuations associated with wildlife habitat rehabilitation would have on cultural resources. This required an understanding of past fluctuations only accessible through geomorphic, paleoenvironmental, and paleohydrological analyses not traditionally included in heritage resources survey. The success of the study stems from multidisciplinary data collection coupled with interdisciplinary analysis aimed at data integration and interpretation.

The Flood Control Act of 1944 and the Growth of American Archaeology

The Flood Control Act of 1944 authorized one of the largest civil works programs ever undertaken in the United States: the Smithsonian Institution’s River Basin Surveys (RBS) and the National Park Service’s Interagency Archaeological Salvage Program (IASP). The programs began in 1945 and continued until 1969 and, collectively, had profound effects—methodological, theoretical, and historical—on American archaeology. They piqued the public’s interest in heritage preservation, were a major factor that led to the passage of the National Historic Preservation Act of 1966, and helped stimulate the “New Archaeology” of the late 1960s and 1970s. The session will examine some of the important impacts of these two programs on the development of American archaeology as well little known topics such the
role of women, the development of historical archaeology, and the use of forensics anthropology and heavy equipment. Although the impacts of these programs are still being felt 50 years after they were established, many archaeologists today who are beginning their careers (and had RBS/IASP alumni as instructors) are not aware of or do not appreciate the impact the RBS and IASP had and still have on the discipline.

The View from Bluff’s Edge: South Sowa, Botswana in the Early Iron Age

By the 9th century A.D., a well-established sphere of interaction existed throughout Early Iron Age southern Africa which connected multiple areas of resource production to the broader Indian Ocean trade network. Within southern Africa at this time, several locales acted as places of production and economic importance, with the Shashe-Limpopo Valley as an emergent center of regional power. Still, much remains to be learned about the dynamics of the interaction as a whole, and especially about the role of lesser nodes within it. The South Sowa area of northeastern Botswana was a part of this sphere, but has not usually been considered a particularly productive area within it. This area is thought of as a cultural periphery to the Early Iron Age. However, recent research at some of the many sites in the South Sowa area shows that it participated in this network more than previously believed. This paper highlights finds from Thaba di Masego, a site excavated in 2012. The data collected provide a systematic look at economic and social behavior in the South Sowa Early Iron Age, and offer a perspective by which to complement the current models on interaction and trade.

As Diverse in Life as in Death? A Bioarchaeological Approach to Social Identities at the Tiwanaku Omo M10 site, Moquegua, Peru

Understanding the construction of multifaceted social identities is critical to our interpretation of community interactions and state expansion during the Middle Horizon. Here we address how individuals living within peripheral Tiwanaku (A.D. 500-1000) sites, one of the earliest expansive states in the South Central Andes, incorporated and performed diverse ethnic, occupational, and other social distinctions throughout life. Human remains retain records of individuals’ life experiences and repetitive practices that complement social distinctions represented in mortuary contexts, which often reflect the communal identities and memories of the living. Bioarchaeological approaches integrating comprehensive mortuary analyses are therefore uniquely suited to reconstruct individuals’ behaviors throughout life that may differentially align with social distinctions marked in death. Recent excavations and ongoing analyses of over 200 burials from the Omo M10 site, a Tiwanaku colony in Moquegua, Peru, reveal potentially diverse groups sharing mortuary spaces and practices under the auspices of the expansive Tiwanaku state. This paper examines skeletal indicators of individuals’ experiences in life, including cranial modification techniques and skeletal pathology, and encourages the application of ongoing isotopic paleomobility and paleodiet research to address the potential social diversity of Tiwanaku migrants in Moquegua.

An Overview of Chinese Woodchopping Camps near Aurora, Nevada

In 2013, the University of Nevada-Reno, in conjunction with the U.S. Forest Service’s Passport in Time program, conducted a series of surveys of late 1800s Chinese woodchopping camps in western Nevada. This paper will explore the preliminary results of those surveys with particular attention paid to the architectural and artifactual elements of the camps. It will also discuss the spatial and temporal differences between rural woodchopping communities found on Table Mountain with the urban Chinese communities in the nearby mining boomtown of Aurora.

The Cross-Cultural Analysis of Pre Columbian Central American Ceramic Figurines

The creation of figurines in ancient societies denotes not only artistic trends, but also how people
constructed ideas about identity, beauty, gender roles, status, and power. To explore how these ideas differed in the Precolumbian cultures of Central America, I analyzed more than 100 complete figurines in the collections of the National Museum of the American Indian, Smithsonian Institution. For example, figurines sitting in a seat from the Greater Nicoya culture are believed to be representations of elite; however, Greater Chiriqui figurines, which are also typically seated but not in a seat, seem to be representations of quotidian society. Attributes including gender, clothing, hairstyle, jewelry, body adornment, and posture were examined across six archaeologically defined cultural regions that include present day Guatemala, Belize, El Salvador, Honduras, Nicaragua, Costa Rica and Panama. The role of these figurines in constructing cultural identity, reinforcing gender roles, etc… over time and space is evaluated using supporting archaeological evidence, historic documents and ethnographic research.

[23] Ecological Niche Modeling and the Spread of Agriculture to the Tibetan Plateau

Moving agriculture into the highlands of the Tibetan plateau was a challenging process. A crop cultivars phenology determines the ecological niche this species is able to occupy. Short growing seasons, cold winters and spring frost mean that the Tibetan plateau presented considerable challenges to the movement of domesticates into this region as many of the species involved were able only to occupy a limited niche. Using new developments from the field of ecological niche modeling, this paper outlines the constraints associated with practicing a range of different crops on the Tibetan plateau and in the foothills of the Himalayas. This data is interpreted in the light of new archaeobotanical evidence from the Plateau itself and the western Sichuan highlands.

[10] Petrographic Analysis for Quartzite Sourcing in the Gunnison Basin, Colorado

Recently, Pitblado et al. (2013) published a preliminary geochemical (LA-ICP-MS) sourcing protocol for Upper Gunnison Basin quartzite deposits. They noted that petrographic analysis, conceived from the beginning as a prospective means of fine-tuning geochemical results, was ongoing. This poster reports the results of the petrographic analysis on 61 samples (approximately 15% of the geochemically sourced specimens). As hypothesized, the petrographic data are broadly consistent with those derived from geochemical testing, but also reveal characteristics that discriminate among Gunnison Basin quartzite sources with even higher resolution than geochemistry alone. The petrographic results separate the quartzite sources identified into consistent discrete groupings, demonstrated by multivariate analyses including principal component and discriminant analysis. Establishing a robust methodology for sourcing quartzite is important for Gunnison Basin archaeologists who typically encounter lithic assemblages overwhelmingly dominated by quartzite. Applying this to a very diverse environment as in the Rocky Mountains, allows for a view on prehistoric life that has never been examined in this type of detail before. Ultimately, this will enable archaeologists to reconstruct prehistoric hunter-gather land-use patterns in the Gunnison Basin and serve as a model for other archaeologists around the world who encounter artifacts and features made of this ubiquitous rock type.

[344] Zuni Chacoan Communities: The Archaeology of Village of the Great Kivas

Perched at the base of a prominent cliff above the Nutria River is the Village of the Great Kivas great house. Beginning in the mid-eleventh century, numerous small sites were constructed around the great house, establishing the Village of the Great Kivas community, which is a cluster of residential sites distributed along the fertile floodplain of the Nutria River. Although the area was not used prior to the A.D. 900s, by the mid-eleventh century, this location became the center of an expansive Chacoan community. This paper is about outlying Chacoan communities in the Zuni region and beyond. Recognizing how Zuni great house communities are different or similar to other Chacoan communities has implications for understanding the relationships that existed between Chaco Canyon and its regional system. I focus on four characteristics of Chacoan communities and contend that these factors, in part, directed Chacoan community development in the region. The similarities and differences between these themes begin to illustrate how Zuni great house communities participated in the Chaco world and how local developments
D'Andrea, William (Lamont-Doherty Earth Observatory of Columbia University) and Max Friesen [201] *Climate Change and Culture History in the Eastern North American Arctic*

With its limited biological productivity, marked seasonality in resource availability, and notable human dependence on weather-related phenomena such as sea ice cover, the eastern North American Arctic seems an ideal place to examine past interactions between humans and climate. Indeed, since the 1960s climate change has served as a central framework for the interpretation of prehistoric cultural developments in the region. However, significant challenges remain for this endeavor, including the large size and variable geography of the eastern Arctic, and the sparse and uneven nature of observational data from archaeological and paleoenvironmental fieldwork. Here, we provide an up-to-date synthesis incorporating the latest chronological information for the major pan-eastern-Arctic prehistoric events and processes of the last 5,000 years, including the initial peopling by early Paleoeskimos, the origin of the Dorset, the Thule Inuit migration, and post-Thule population movements. We compare this chronology to the growing number of regional climate reconstructions spanning the same time period to assess the degree to which major events in Arctic prehistory were directly impacted by changing climates, as opposed to other factors such as intersocietal interaction and cultural or social processes “internal” to past societies.

Daneels, Annick (IIA-UNAM Mexico) [204] *Stone Sculpture in the Lower Cotaxtla Basin: Small Is Significant*

The paper will present data on a dozen stone sculptures from the Lower Cotaxtla basin, ranging from plain stelae to complete yokes and figurative statuettes dating from the Preclassic to the Classic Period (800 B.C.-A.D. 1000), most of them unpublished. The relative paucity and modesty of the corpus in this region is contrasted with the much more impressive record of the neighboring Mixtequilla region. I will consider factors as the early inception of looting and local cultural dynamics to evaluate the importance of stone sculpture as part of sociopolitical discourse in early state-level society.

Daniels, James (ASM Affiliates) and Geoffrey Braswell (University of California San Diego) [138] *Sourcing Obsidian from the Southern Belize Sites of Lubaantun and Nim Li Punit Using pXRF*

Portable X-ray fluorescence spectrometry (pXRF) was used to analyze 203 obsidian artifacts from the Mayan site of Lubaantun and 612 obsidian artifacts from nearby Nim Li Punit, both located in the South Toledo District of Belize. The elemental spectrum of each assayed artifact was visually compared to the spectra of artifacts with known geological provenience to determine the provenience of the unknown samples. The raw elemental data for each artifact were then calibrated and quantified into parts per million for statistical analyses including group classification using Mahalanobis distances to verify geological provenience. The results demonstrate that the majority of obsidian artifacts from both Lubaantun and Nim Li Punit were manufactured from material from the sources of El Chayal and Ixtepeque. Other less represented sources include Ucareo, Zacualtipan, Otumba, and Pachuca. While each site procured obsidian from the same sources, the spatiotemporal patterns in the distribution of the different sources of obsidian at these sites suggest different obsidian procurement strategies between the two sites. The qualitative assessment of the elemental spectra reveal that the quantification and statistical analysis of data obtained from extremely thin obsidian artifacts can lead to unreliable source assignment.

Daniels, Brian (University of Pennsylvania), Sasha Renninger (University of Pennsylvania) and Richard Leventhal (University of Pennsylvania) [273] *Evaluating the Impact of Archaeological Context on the Antiquities Market: A Case Study*

A key question in the debates about antiquities sales is whether objects found prior to 1970 carry a price premium when sold in the art market. Such antiquities are often seen as being more "legitimate" and therefore more valuable, since they entered the market prior to the date of the 1970 UNESCO Convention—the international agreement that is often seen as the ethical benchmark in halting the illicit trade. Although much press attention has been given to the seemingly inflated prices of antiquities with a pre-1970 provenance, scholars like Neil Brodie and Donna Yates have argued recently that there is no...
firm evidence to support these claims among high-end sales. Within this paper, we analyze 3,360 Pre-
Columbian objects listed for auction at Sotheby’s and Christie’s between 2000 and 2010. First, we offer
a methodology and preliminary findings related to the impact of archaeological context on final sale price
across this particular segment of the art market. Second, we find that there is a price differential between
the pre- and post-1970 objects within the lower end of the art market.

[254] Family Making of Prismatic Blades. The Pecked and Ground Platform Preparation at the
Beginning of Manufacture Process: A Good Indicator of a Household Organization of Production
with Division of Labor
Obsidian cores with a pecked and ground platform for the production of prismatic pressure blades
spread widely during the Postclassic Period in central and western Mesoamerica. This technological
innovation could simplify the removal of blades and thus reduce pressure production errors. It also
coincides with a “banalisation” of the prismatic blade as an ubiquitous artifact. In the Tarascan area,
pecked and ground platform preparation occurs very early in the “chaîne opératoire”, before the shaping
of the polyhedral core. We suggest that this practice could indicate a division of labor within the family
structure.

Power-Array Archaeological Data Recovery Project
The Middle and Late Archaic technologies of the Sonoran Desert are known from sites that occur either
on the upper bajadas or in the floodplains. Recent excavations at Luke Air Force Base in the Phoenix
Basin of Arizona resulted in the first robust collections from the lower bajada, an expansive landscape
characterized by a narrow range of wild plant foods, limited game animals, and little water. Despite these
constraints, Archaic period foragers invested heavily in the procurement, transport, and manufacture of
formal ground stone technologies. Typical manos, metates, pestles, and mortars are accompanied by a
distinctive tool category that does not articulate with other ground stone implements at the site. This
poster describes the morphology and wear patterns that define the so-called “lukeolith,” formally shaped
implements that do not have a functional analog in the Southwest. Preliminary microanalysis suggests
these implements may have been used to work soft or pliable materials and alternative explanations are
offered citing cross-geographical and cultural comparative examples. Additionally, we present the results
of a geospatial analysis situating the Lukeolith within an intrasite context which highlights their spatial and functional relationships with traditional ground stone artifact types.

[144] Today's Understanding of Casas Grandes' Architectural Variety
Recent investigations in the Casas Grandes area have led us to a new perspective regarding its architectural variety. In the past, the Paquime construction type was accepted as a norm for other types of pueblo construction inside the region. Now we can find other types outside Paquime; among its closest neighbors. The first one is comprised by Paquime's thick-walled architecture described by Di Peso, the second one is a thin-walled construction type found in several sites inside the core area, like site 231; and the simplest architecture, a third type characterized by really thin walls. The former being found inside plazas, needs minimal construction. Using visual, descriptive and statistical comparisons to divide recently excavated Casas Grandes sites by their architectural differences, we will try to demonstrate the relationship between the three architectural types first described. Also, current chronological data and associated materials help us to point out chronological similarities and the short or long term use of such construction types. As a result, we expect to find out that the region of Casas Grandes had a significant population growth in where the addition of temporal edifications in the sites involved was used in a time period.

[19] Literal Providers of Food and Drink: Examining Inka Imperial Control through Pottery
The site of Pachacamac on the central coast of Peru was an important ritual and pilgrimage center long before the site came under Inka control. While most of the Inka presence on the central coast was minimal compared to elsewhere in the empire, Pachacamac experienced a strong Inka presence that included the construction of new prominent administrative and ritual centers. While the Inka often used local artisans to reproduce imperial-style material culture in many places they conquered, new characterization data using neutron activation analysis of Inka ceramics from ritual contexts at Pachacamac suggests the importation of serving vessels, such as plates, bowls, and keros. The importation of finely-made ceramic serving vessels in distinctive imperial styles to Pachacamac for use in ritual and feast contexts draws a strong intentional connection between the ceremonies that these vessels are used for and the Inka sponsorship and promulgation of these events.

Davenport, Anna (University of Winchester)

[283] Can the Forensic Archaeologist Ever Be Truly Independent?
There has been a recent explosion of research into cognitive bias within forensic investigations mainly due to the proposed changes in UK legislation. This paper provides an overview of a range of biasing factors that may influence search, location and interpretation of the clandestine depositions within the forensic record. This paper considers the complex nature of decision making and responses to intelligence at the major crime scene. In the UK it is usual for the forensic archaeologist to work closely with a range of experts and as such the archaeologist is used to adapting their forensic strategy in light changing intelligence. This paper briefly examines the relationship with dog handlers within the search and location of clandestine depositions and the relationships with other experts in light of maintaining the independence of the forensic expert. It draws upon cases where contextual information has influenced the interpretations reached by the forensic archaeologist and concludes by examining the impact these potentially biasing factors may have in a courtroom setting in the UK.

[114] Geoarchaeological Evidence for a Pre-Clovis Mammoth Locality near Lindsay, Montana
Stratigraphic context, radiocarbon dates, and site-formational studies indicate that a nearly complete skeleton of a Columbian mammoth recovered in an upland north of the Yellowstone River, in eastern Montana, is associated with pre-Clovis human activity. Stratigraphically, the mammoth remains were embedded in silts and below a buried soil A horizon. The buried A horizon can be correlated with a regional paleosol dated to the Pleistocene-Holocene transition. Radiocarbon measurements indicate the mammoth is older than 12,000 radiocarbon years before present (RCYBP) and possibly closer to 12,300-500 RCYBP, thus indicating it dates to before Clovis. Site-formational evidence includes bone damage, spatial arrangement, and cobble-sized rocks in the upland silt and associated with the skeleton. Bone damage includes cutmarks on rib and calcaneous bones. Human activity is suggested by green bone damage of a humerus, possibly to enable marrow extraction. Stacking and rearrangement of other skeletal parts also suggest human activity. Eight quartzite fragments underlie or lie beside parts of the skeleton. Geoarchaeological evidence, including the stratigraphic context, radiocarbon age, marks on bones, green bone damage, stacking, and patterned quartzite rock distribution, suggests pre-Clovis human involvement with the Lindsay mammoth.

[24] Research Progress at the Cooper's Ferry Site, Idaho
Excavations conducted by Keystone archaeological research fund supported archaeologists at the Cooper's very sites of Western Idaho since 2009 have largely progressed through the upper half of the stratigraphic record in a large block excavation termed Area A. In 2012, additional deeper excavation units were opened in an effort to explore the stratigraphic record on the site's eastern half where previous archaeological excavations were conducted in the 1960s and 1970s (designated Area B). To date, excavations in Area A have revealed cultural components dating between about 8452 to 9140 radiocarbon years before present. Excavations in Area B since 2012 have accessed deeper aeolian loess and alluvial deposits containing intact archaeological components that include several pit features and a larger feature that may represent a semi-subterranean house foundation. All of these features have produced early Western Stemmed Tradition projectile point variants. Forthcoming radiocarbon dates will clarify the age of these earlier Area B cultural components.

[35] Stone Blades in the Neighborhoods of Harappa, Pakistan
Stone tools are often overlooked in the archaeology of complex societies with metallurgical technologies; however there are many different aspects of information that can be gleaned from these datasets. This paper examines lithics of the site of Harappa, Pakistan (3200-1900 B.C.E.), which was a sprawling and dense urban center and is the type-site of the Bronze Age Indus or Harappan Civilization. Despite the relatively widespread availability of metal tools, stone tools at Harappa are the second largest material class after ceramics. Prismatic blade tools were used in a diverse variety of crafting and domestic activities and in many different social and economic contexts. A functionally aimed typology and an overview of the lithic industry will be provided and the role stone tools played in the economy will be highlighted. The intra-site spatial relationships and distributions of these tools from excavated contexts in the city provide social and political insights into the variable nature of administrative and social subdivisions.

[38] House for the Living, Home for the Dead: Mortuary Activity in the Muru Ut Pata Area, Tiwanaku
In the latter part of the Middle Horizon (A.D. 800-1000), previously unoccupied areas around the
megalithic ceremonial core of Tiwanaku came under settlement. Whether as a result of a reorganization of space within the core, displacing previous residential activity and forcing new construction further away from the monuments, or as a result of the influx of new residents drawn to the site of Tiwanaku from the surrounding areas by the variety of social, economic, and ritual interactional opportunities, these newly settled areas became the loci of quotidian activity. Within this dense center of population, families constructed their physical shelters as they built their interdependent social networks; and into the foundations and floors and patio spaces of their built environment they incorporated their dead. Residential groups authenticated their claims to these new spaces by integrating their deceased members into their living spaces. This paper will examine burial practices as social statements by the living by focusing on the construction of the burial feature itself (burial goods, body positioning, tomb style, and location within the residential structure) and also examine burials in terms of the individual bodies there contained (sex, age, presence of caries, and cranial vault modification).

Davis, Christopher

Pleistocene Amazonian Archaeoastronomy as a Potential Source for South American Ethnoastronomy Traditions

Several rock paintings aligned to the sky themes they depict survive as evidence of an archaeoastronomy tradition that developed in the mountains of Monte Alegre on the Amazon River in Pará, Brazil. My excavations unearthed artifacts, pigment, and a painted stone in stratigraphic layers that were radiocarbon dated to 13,000 cal yr B.P., an age consistent with Dr. Anna Roosevelt’s previous research at Caverna da Pedra Pintada nearly half a kilometer away. I incorporate gigapan robotic photography, correlation D-stretch image analysis, and astronomy software to reconstruct the ancient skies in relation to the art, revealing that the mountains provided the elevation for Paleoindian artists to orient sunset positions and other sky phenomena to the horizon and paint them at the spot of observation, resulting in a record of the annual solar cycle on sandstone. This allowed for seasonal rain and animal variations to be associated with periodic celestial sightings. A grid-like tally image might reflect the culmination of this knowledge into one of the earliest potential calendars in the Americas, hinting toward this region as a possible source for later South American ethnoastronomy traditions, and perhaps explaining why rainforest animals (monkeys, anacondas, and jaguars) appear in astronomy-related Andean iconography.

Davis, Aaron (California State University, Northridge)

Practical and Symbolic Functions of Chacoan Roadways in the Sand Canyon/Goodman Point Region

Modern culture has a strong tendency to suggest that roads are strictly for movement, for getting people from point A, to point B, but this is a limited perspective. Roads serve not only as “structures” of movement but also as constructed landscapes, landmarks symbolizing different meanings to those who travel and experience them. These symbolic functions, however, are created and maintained through the practical functions of these roads themselves. For the purpose of this research, practical function and symbolic function are terms used to differentiate intended uses of roads from the meanings they represent. Practical functions can include facilitation of movement, political expansion, trade, and other economic activity, and religious ceremonies. Symbolic functions include the role of roads as tangible evidence of ideas, relationships, connectivity and even cosmological meanings which are established through their use. This study is set in the Sand Canyon/Goodman Point region of Southwest Colorado, where three Chacoan era pueblos - Casa Negra, Goodman Point, and Shields Pueblo - are interconnected by numerous roads and trails. Further evaluation and GIS analysis allow the various practical and symbolic characteristics of this network to be better understood.

Davis, Jera (University of Alabama)

Into the Great Wide Open: Plazas and Polity in the Mississippian South

Identity, memory, and plazas were inextricably intertwined in the Early Mississippian societies of the ancient American South. Contrary to earlier portrayals of Mississippian plazas as unaltered, empty space delineated by earthen mounds, they are now understood as layered constructions encapsulating much about site histories. Because their massive scale and central placement necessitated the destruction or burial of pre-existing community plans, including many of the public contexts where differences in identity and status were first engaged, Mississippian plazas provided a monumental tabula rasa where interest groups could embrace or reject conventional practices within a novel frame of reference. This paper uses landscape-scale geophysical data from Moundville, one of the largest Mississippian centers, to explore the plaza’s fundamental role in the site-wide reorganization of space and architecture that coincided with
polity formation.

[273] Temple Looting in Cambodia: Mapping the Networks

Empirical studies of the international market in looted antiquities have tended to focus on the source end, through interviews with looters, or the market end, through interviews with dealers, collectors and museums. Trafficking, in the sense of the movement of illicit artifacts across borders from source to market, has until now been an empirical black hole. Here we present the first empirical study of a statue trafficking network, using data gathered through oral history interview methods in an ethnographic criminology fieldwork project in Cambodia and Thailand. The data begin to answer many of the pressing but unresolved questions in academic studies of antiquities trafficking, such as whether organized crime is involved (yes), whether the traffic in looted objects overlaps with the insertion of fakes into the market (yes), and how many stages (surprisingly few) there are in this type of trafficking network between looting at source and the placing of objects for public sale in internationally respected venues.

Dawson, Helen (Freie Universität, Berlin)

[181] Sense of Place and Identity in the Prehistoric Central Mediterranean Islands

This paper will focus on the relations between place and identity in the context of Sicily's minor islands during the Neolithic and Bronze Age. Natural features contribute to an island's distinctiveness or "sense of place". Insularity may result in cultural isolation; nonetheless, over time, prehistoric island communities established extensive networks of interaction, developing distinct identities and constructing meaningful topographies. Thus, from a theoretical and practical perspective, islands and their multiple geographical and cultural dimensions offer excellent case studies for analyzing place-making and identities, through combined quantitative and qualitative spatial analysis. GIS and phenomenological/experiential fieldwork, traditionally separate methodologies, provide suitably complementary means for investigating the setting, location, and orientation of domestic, funerary, ritual, and monumental sites within the islands. These features are likely to reflect the islanders' perceptions of their island worlds, their relations to the mainland, and to the sea. Comparisons between the islands can shed light on issues of insularity, space-related identity, liminality, physical vs. symbolic boundaries, place-making and connectivity. Ultimately, these questions can lead to a deeper understanding of complex cultural dynamics in the prehistoric Mediterranean.

Day, Peter (University of Sheffield), Eleftheria Kardamaki (University of Heidelberg), Aikaterini Demakopoulou, Joseph Maran (University of Heidelberg) and Alkestis Papadimitriou (Greek Ministry of Culture)

Transport Stirrup Jars are important as they moved as amphorae in large quantities between the 'Minoan' and 'Mycenaean' worlds and because they sometimes feature inscriptions in Linear B, reflecting elite control of production and consumption in Knossos and Chania in Crete, as well as in a variety of mainland 'palaces.' This makes the vessels key to our understanding of palatial Bronze Age economies, their modes of control, their collapse and successors. Recent analyses published from "Minoan" Kommos on the southern coast of Crete have shown that in addition to TSJs, Canaanite Jars from the Levantine coast were transported to Crete. This evidence of large scale commodity exchange has encouraged us to look to the Mycenaean world and specifically at the fortified citadels of Tiryns and Midea. There we have analyzed by thin section petrography a large number of TSJs and a range of Canaanite Jars, which are known to have transported commodities such as resins and oils. Unusually, these vessels are found in LHIIIB2 contexts, in destruction deposits at the twilight of the Mycenaean Palaces. They reflect an intense, unexpected interaction between the Mycenaean world, what is thought of as a 'post-palatial' Crete, and the wider Eastern Mediterranean.

[33] Black Hole Places: Cenotes Symbolism in Maya Landscape

The program of Yucatecan cenote investigation directed by the senior author has documented extensive modifications of these subterranean environments by the ancient Maya. These discoveries have
revealed as no previous investigations, the tremendous ritual significance of cenotes in the ritual life of the ancient Maya of northern Yucatan. The popularity of the term “cenote” has grown throughout the twentieth century and unfortunately obscures the relationship of this work to the larger issue of the use of subterranean spaces by the ancient Maya. Cenotes appear to carry the same meaning as caves in Maya iconography where both generally represent cavities within the earth. Indeed, the name Chichen Itza refers to the Sacred Cenote at the site but the name uses the term ch’e’en which generally refers to a cave rather than as dzonot, from which the term cenote is derived. One depiction of the cenote/cave in ancient Maya iconography is the skeletal centipede maw. The analysis of the ancient iconographic motif in light of recent investigations allows us to gain a better appreciation of the ancient significance of these geological features for the ancient Maya.

De Carteret, Alyce
Recent research has indicated that some Classic Maya polities (e.g., Piedras Negras) became associated with particular styles of ceramic vessels. This paper will investigate the phenomenon of polity-wide pottery, here termed “polity style,” in the Maya lowlands during the Classic period (ca. 250 – 900 CE). Building upon existing anthropological models of elite consumption as well as ethnoarchaeological observations on vessel design replacement, this investigation will provide a model for the sociopolitical circumstances under which new aesthetics are adopted and why certain styles may be chosen over others. As its case study, this paper will present ceramic evidence from the site of El Zotz, located just to the west of Tikal in the department of Petén, Guatemala. Over the course of the Early Classic period (ca. 250 – 600 CE), the site exhibited a marked shift toward the production and consumption of red ceramics, indicating—as this paper will suggest—an attempt by some El Zotz elites to evoke mytho-historic ties to their landscape in a period of political vulnerability.

[249]  Archaeological Obsidian Provenance of Several Italian Neolithic Sites Using a Non-Destructive XRF Method
The provenance of 1.400 archaeological obsidian fragments was determined using the non-destructive XRF (X-ray Fluorescence) analytical method, based on the secondary X-ray intensity (Crisci et al., 1994). To test this methodology, a comparison with the classical XRF method on powders (major elements and selected trace elements concentration as Nb, Y, Zr, Rb and Sr), was preliminarily carried out on several obsidian samples representative of all the geological outcrops of Mediterranean Area, e.g. Lipari, Pantelleria, Sardinia, Palmarola, Hungary and the Greek islands of Melos and Giali (De Francesco et al. 2008). The provenance of the entire archaeological obsidians is determined by comparing their composition with that of the quarry obsidians in the whole Mediterranean area. Just five chemical elements (the intensity ratios of Nb, Y, Zr, Rb and Sr) are sufficient to characterize the different places of origin because they are particularly indicative of the genetic processes which produced obsidian. With the non-destructive XRF methodology has been analyzed about 1.400 archaeological obsidian fragments, coming numerous Italian Neolithic sites of the Tuscan archipelago, Tuscany, Abruzzo, Lazio, Campania and Marche region and also from Corsica island. The provenance of the 96% of the archaeological obsidians was successful and indubitably determined.

De Gruchy, Michelle (Durham University)
[257]  Using Routes as a Source of Information to Better Understand a Culture
The ability to quantitatively compare constructed route models against preserved route ways opens up routes as a source of information about past societies. Modelling individual variables and quantifying their similarity against preserved routeways measures the relative importance of that variable in route choice decisions, especially in cases like the hollow ways of Northern Mesopotamia where the routes are the result of numerous journeys compacting and eroding the ground beneath, and are not formal planned and paved roads. After introducing the methodology, an overview of results of this analysis from Northern
Mesopotamia will be presented, which highlight the significance of considering cultural, in addition to physical, variables in understanding route choice.

[126] Controlled Lives, Impoverished Deaths: The Biological Stresses of Institutionalization

Anthropologists have used cadaver samples, such as the Cobb, Hamann-Todd, and Terry collections, for nearly a century to answer questions regarding biological differences and generate forensic techniques to aid in human identification. Few have asked who the individuals that comprise these collections were. My research, focused on answering this question, has used extensive historical documentation to reveal that many individuals in the Terry Collection were of low socioeconomic status and were institutionalized in city and state mental hospitals or long-term care infirmaries. This presentation examines patterns of trauma in a sample of African Americans and Euro-Americans (n = 621) from the Terry Collection to determine if there are differences in fracture prevalence and injury location amongst individuals that were institutionalized versus those that were not. Results indicated that significant differences were present in regard to race, sex, and fractured bones, with institutionalized Euro-American females having higher rates of arm and hip fractures. These findings will be discussed within a historical framework to demonstrate how cultural disease ideologies, structural violence, and disability within Missouri’s state-run early to-mid-20th-century mental institutions does become embodied in skeletal patterns of injury and treatment at death.

[255] Bipolar Knapping in Howiesons Poort: The Case of Grey Sand (Sibudu Cave, KwaZulu-Natal, South Africa)

This paper analyzes the quartz knapping methods in Howiesons Poort and demonstrate how bipolar knapping was a recurring strategy which constituted a microlithism and recycling solution. Therefore, in this communication, I define my concept of microlithic technology, I present the technological results documented in Grey Sand for bipolar knapping (and its distinction from freehand knapping) and, finally, I outline the implications of this technological choice.

[283] A Case Study from The Netherlands and an Update on European Trends and Perspectives in Forensic Archaeology

Forensic archaeology, as a forensic science, seems to be increasing and becoming established across Europe. Although the definition of forensic archaeology differs across European countries, it is usually defined as ‘the application of archaeological principles, techniques and methodologies in a legal context’. A comparison of forensic archaeological practice across the world (Forensic archaeology - a global perspective; Groen, Marquez-Grant and Janaway (eds.), in prep.) summarizes the similarities and differences in the ways forensic archaeology is being perceived and practiced. An additional development is the establishment of a ‘Forensic Archaeology Project Group’ within the European Network of Forensic Science Institutes (ENFSI). The central aim: to introduce the forensic archaeological principles, techniques and methodologies to police crime scenes across Europe. To elaborate on methods used by forensic archaeologists in The Netherlands, a case study involving a recent clandestine burial is presented. The investigation consisted of the systematic excavation, documentation and recovery of the burial. Documentation was carried out with a Total Station, combined in GIS with 3D-scanner images and photogrammetry. The results provided a better understanding of the activities surrounding the time of burial and were used as evidence during the subsequent trial to convict the suspect.

The Vernacular Architecture of Pre-Aztec Mexico: Household Organization and Social Construction in Early Postclassic Xaltocan, Mexico

During the Early Postclassic (A.D. 900-1250) period, Xaltocan, Mexico, was a newly founded and rapidly growing community with an economy based on the exploitation of lake resources. Due to excellent preservation and stratified archaeological deposits, it is possible to observe uses of and renovations of household space over several generations. The study of the construction, use, and organization of vernacular architecture in Xaltocan throughout this period of rapid development lends insight into the reproduction of social identities and the changing nature of household and gender relations through time. I argue that in Early Postclassic Xaltocan, houses were seen as living entities where ordinary people and structures were mutually constituted as part of contextually situated social practices.

Geophysical and Archaeological Investigations of Depressions at Goat Springs Pueblo, New Mexico (LA285)

Six pit depressions were previously recorded at Goat Springs Pueblo, New Mexico (LA285), a multi-component site spanning the Rio Grande glaze ware period (AD 1300-1680). These depressions had been variously interpreted as pit-houses, borrow pits, and/or kivas. In 2011 and 2012 electromagnetic induction surveys were conducted over the three largest depressions in order to determine whether the pits were natural or cultural in origin. A circular low conductivity anomaly was observed in one of the depressions, which we interpreted as a walled kiva. In order to test this a trench was excavated across the western side of the anomaly by the 2013 Texas A&M University Field School. The ground-truthing in this depression definitively showed it to be a masonry walled kiva. Combined, the geophysical and geoarchaeological data from this kiva provides information on how the kiva was constructed, how it was oriented, and the damage done by a 1960 archaeology project. Architectural and ceramic evidence recovered from the kiva provide chronological information that associates it with the occupation of the southern room block.

Oxtankah: A Seafaring Town

The prehispanic Mayan site of Oxtankah is located in the west coast of the Bay of Chetumal, 11 km northward from the border of Mexico with Belize. The chronology of occupation of this settlement began from the Late Preclassic (300-150 B.C.) and finished in the Terminal Classic (A.D. 800-900). In this paper, we will present the history and development of the Maya in this region, the architectural compounds and structures of Oxtankah, and the funerary practices employed by the inhabitants of this settlement. Also, we will show some offerings and garments inside tombs that were related with the representation or personification of certain gods, like Chak-xib-Chaahk, or the emulation of animals, like the xihua, the highly appreciated silver fish found at the site.

De Vore, Steven and Lewis Somers (Geoscan Research USA) [157]

RetroSpection on ProSpection: English and American Views from across the Pond

1893 - Pitt Rivers "thumped" the ground and an early English form of geophysical survey was first recognized. Following World War II, archaeologists in England capitalized on the technologies from the war to develop instruments and techniques for the identification of buried archaeological resources. From surplus equipment and hand-made instruments, the application of geophysical techniques to archaeological prospecting progressed slowly at first, but gained increasing acceptance with the development of newer instruments capable of increased rates of data sampling, storage and processing, along with the advent of solid-state electronics and computers. While European archaeologists took the lead in the early developments and continued such developments to the present, American archaeologists were slower in acceptance. Although the investigations were often successful, their
potential was not fully appreciated until the National Park Service began offering a workshop on the techniques in the 1990s to the archaeological community. Our paper offers an informal look back at these times, instruments, methods, personalities and a few personal anecdotes.

Deal, Michael (Memorial University of Newfoundland)
Ceramic vessels are a hallmark of the Woodland Period in the far Northeast. Archaeologists in the region have used ceramics primarily as a tool for the relative dating of archaeological contexts. However, there have been a number of attempts over the last three decades to develop techniques for the identification of vessel function. These studies have focused on formal comparisons and the analysis of both adhering and absorbed residues. This paper begins with a flashback to the early residue studies of the late-1980s, involving gas chromatography/mass spectrometry (GS/MS) and stable isotope (SI) analyses, and concludes with the preliminary results of an ongoing project combining paleoethnobotany, phytolith and starch research, and residue analyses.

Dean, Emily (Southern Utah University) and Briget Eastep (Southern Utah University)
[328] Looking for Traces of “Leave No Trace”, Archaeological Investigations of the “Leave No Trace” Land Ethic in the Western United States
We present the results of an archaeological study examining the impact of the “Leave No Trace” land ethic on public lands in the western United States. “Leave No Trace” emerged in the U.S.A. in the 1970s. By 1990 the United States Forest Service and the National Outdoor Training Program had created a national educational program promoting the principal tenets of “Leave No Trace,” which include disposing of waste properly, leaving what you find (including archaeological remains), and minimizing campfire impacts. Today, this system of ethics is widespread throughout the United States. It is taught in scouting troops, outdoor recreation classes, posted on trailhead signs, and printed in federal publications and brochures. In 2013 we conducted surveys on federal lands in Utah and Nevada, focusing on backpacking routes and campsites that could be characterized as pre- or post-implementation of “Leave No Trace.” Although there is an extensive literature on the value of “Leave No Trace,” there have been few studies that collect on-the-ground data to assess its efficacy. Our approach, combining the fields of archaeology and outdoor recreation and education, concretely demonstrates the impact of “Leave No Trace” on the conservation and preservation of public lands.

[129] Old Traditions and New Kids on the Block: Enduring Patterns of Funerary Architecture in the Southern Brazilian Shores
Located in a context that, from both a geographical and a historical perspective, situates it in between the long-lived sambaqui (shellmound) and the latecoming Southern Je cultures from the southern Brazilian coast, Galheta IV is a funerary site bearing characteristics from both cultures, thus highlighting the fluidity of the contact between them. If, on the one hand, it bears peculiar elements related to the Je, it also is harmoniously inserted in a landscape long dominated by the presence of the sambaquis.

DeBoer, Warren (Queens College CUNY)
[281] Pots for Tots II: The Ceramic Art of Shipibo and Mimbres Children
Given renewed interest in the mechanisms of cultural transmission, it is surprising that so little information is available concerning the acquisition of culturally-specific art styles in non-Western, non-school settings. This is particularly so in the case of geometric design styles, as opposed to more commonly studied representational art. This paper compares designs painted on eleventh to twelfth century Mimbres pottery that Patricia Crown has attributed to child artists with children’s ceramic art of the contemporary Shipibo of the Peruvian Amazon. The maturational mastery of angle, layout, composition, symmetry, and other design features as well as the various teaching aids provided by adult artists are outlined and compared. Although conforming to selected aspects of the universal developmental stages proposed by Piaget and others, the aesthetic gestalt approach of Kellogg, or the problem-solving perspective favored by Goodnow, the Shipibo and Mimbres cases appear to better illustrate the seamless entanglement of ontogenetic predisposition and cultural environment and, in this sense, contribute to the ongoing dissolution of nature-nurture polarities.
North Carolina at Chapel Hill)

[31] The Distributed Household: A Study of Plant and Mollusk Data from K’axob, Belize

One impressive aspect of Norman Hammond’s work at Cuello was his commitment to archaeobotanical investigation. The flotation program at Cuello was extensive and among the first of its kind in the Maya area. From this study, we gained an immensely improved inventory of plants available to residents of Cuello based on carbonized seeds. Plant and faunal remains were integrated to examine economic and environmental changes through time. This paper builds on research at Cuello through the examination of plant and mollusk data from Formative- through Classic-period K’axob. We examine two structures at K’axob that have been considered the remains of adjacent households. In the study of ancient Maya sites, scholars often use disparities between alleged dwellings to argue for intrasite hierarchy. We examine the relationship between a larger and smaller structure, using plant and mollusk data to analyze changes in the organization of activity areas through time. The results counter what might be expected based on prevailing ideas of intrasite hierarchy using platform size and configuration. We suggest instead that, by the Classic period, households were distributed across more than one structure. Finally, we explore the implications of the data for changes in cuisine and social interaction through time.

Deibel, Michael (Earlham College), William Whitehead (University of Wisconsin- Fond du Lac), Corinne Deibel (Earlham College) and Emily Stovel (Ripon College)

Obsidian and ceramic studies in the San Pedro de Atacama (SPA) area of northern Chile have the potential to supplement and expand on studies of trade, resource procurement, and tool manufacture. Ceramic studies have been the basis for many works, however, no large-scale scholarly focus on SPA obsidian artifacts exists, making this important resource under-represented in the literature and not fully understood in comparison with textiles, organic artifacts, and ceramics. Our recent study analyzed over 1000 obsidian artifacts collected from the surface of the formative archaeological site, Coyo Aldea, and the ayllu of Solor, using handheld X-ray fluorescence (hhXRF) and handheld Fourier Transform Infrared spectroscopy (hhFTIR). A large collection of ceramics from Coyo Aldea were also analyzed the same methods. We use these results to explore how local obsidian resources were utilized in the past, focusing primarily on changing use of raw materials and projectile point morphology as a proxy for time. We will present a preliminary methodology for comparing these patterns to information from obsidian and ceramic studies using hhXRF and FTIR.

Dekle, Victoria (University of Kentucky)

[308] Artistic Style and Identity among the Late Archaic Peoples of the Southern Atlantic Coast

This paper presents the proposed questions and preliminary results of an ongoing research project of artistic expression in material culture during the Late Archaic period through the southern Atlantic Coastal Plain of the southeastern United States. The material cultures of the Stallings, Thoms Creek, Orange and other archaeologically defined cultures of the area have been unevenly documented across archaeological sites and research agenda. This project approaches the material culture of the Late Archaic context through structural and post-structural analyses connected by the complex and dynamic concept of art.

The Contradictions of Slavery in Colonial Jamaica’s Plantation Mode of Production

A primary tenet of Marxist historical analysis is the contention that society simultaneously produces and is produced by the relationships people have with each other and the material world in which they live. This material world, expressed in the archaeological record, can be interpreted to understand the nature of past social and material realities produced under an operative mode of production. Colonial Jamaica was shaped by a variant of the capitalist mode of production, the Plantation Mode of Production. Under this mode the relations of production were defined by chattel slavery, a condition that objectifies people to define them as exchangeable components of the means of production. Yet Jamaica’s mode of production developed a critical contradiction between the organization of labor for local production, in which enslaved workers controlled the products of their labor and the mechanisms of exchange, and that for export production, from which they were completely alienated from those products and mechanisms. This paper examines the dialectical nature of this contradiction in the Plantation Mode of Production and its effects on the development of social realities through the archaeological analysis of Marshall’s Pen, an early 19th century coffee plantation.

Dello-Russo, Robert (Office of Archaeological Studies / Museum of New Mexico) and Vance Holliday (University of Arizona / Depts. of Anthropology & Geology)

Paleoindians in Socorro County: How the Cramer’s Helped Facilitate 10 Years of Research Collaboration in West-Central New Mexico

Many of my first 20 years of archaeological research occurred in Socorro County, New Mexico and, by the early years of the new century, I had finally managed, with some funding from the New Mexico Historic Preservation Division, to undertake pilot research efforts at the deep rock shelter site known as Lemitar Shelter. This site, as it turned out, was the location of the first archaeological excavations undertaken by C. Vance Haynes in the early 1950s. By turning to him for background information, we began a fruitful collaboration which expanded to include Vance Holliday at the University of Arizona and, through the Argonaut Archaeological Research Fund (AARF), to include Joe and Ruth Cramer. Our AARF-funded work at Lemitar Shelter has been followed by interdisciplinary research, since 2008, at the Water Canyon site. This research is still on-going and it is abundantly clear that funding from the Cramers over these years has helped establish the Water Canyon site as one of the most significant, multi-component Paleoindian sites west of the Pecos River.

DeMaio, Justin (University of Nevada, Las Vegas)

Investigating Lithic Learning Frameworks at the Harris Site

Utilitarian technology is often studied to understand what specific functions and activities these items represent in a past population’s daily life. However, it is important not to forget that technology manufacture, use, and discard are embedded in a social context. Flintknapping is a skill that requires close instruction and training so that the desired outcome can be achieved. This training requires daily mentoring from other individuals in the community, many times within one’s own family. These daily interactions create learning frameworks through which craft knowledge is transmitted. Technological style and domestic processing activities can be used as an indicator of social identity, therefore enabling these learning frameworks to be traced. The Harris Site, a Mimbres Mogollon community, has evidence of corporate group organization beginning in the Late Pithouse period (A.D. 500-1000). This is supported by clusters of pithouses sharing similar household traits and extramural areas. The knowledge of craft manufacture and daily tasks transmitted through corporate groups may result in different technological styles of material goods, especially in domestic contexts. This research investigates if learning frameworks exist within these clusters of households by examining the lithic artifacts recovered from the contexts of these pithouses.

DeMaio, Joanne

The Adair Site: Ouachita River Valley Relations through Ceramic Analysis

The Adair site (3GA1) is a Northern Caddo site located in the Upper Ouachita River Valley. The site, located on a terrace overlooking the northern fork of the Ouachita River, was composed of one 3-meter high triangular pyramidal mound, at least two other low mounds, borrow pits, structures, middens, and cemeteries. Although it has long been considered an important elite site, due to that it is the only mound complex in the area, little is known about the people who once lived there. The site was excavated by the University of Arkansas Museum from 1929-1932 and again from 1938-1939, but little information from the
excavations still exist. This study looks at the whole vessels that were excavated from the site. The vessels from Adair were analyzed and compared to sites in surrounding areas, the Standridge Site (3MN53), the Poole Site (3GA3), and the Hardman site (3CL419). By looking at all the collections concurrently, a hypothesis about the people who once lived at Adair, and how they interacted with the people around them was formulated. This study was able to provide insight into settlement systems, social influences, and societal hierarchy that was apparent in the Upper Ouachita River Valley.

[128]  **Boundaries and Networks of Interaction on the Highland/Lowland “Frontier” of Classic Maya Civilization: Evidence and Interpretations from Cancuen and the Verapaz Highland Region**

For 13 seasons the Cancuen Regional Archaeological Project has been investigating the zone of direct interface between the southwestern Peten lowlands and the Maya southern highlands, ecologically and geologically dramatically contrasting zones. Explorations of the Maya lowland southern frontier port and gateway center of Cancuen have discovered much evidence of intensive economic exchange with the piedmont and highlands to the south – both long distance and regional, and of both exotics and commodities. Meanwhile, project excavations in nearby highland Verapaz sites, just south of Cancuen, have recovered strikingly different material culture with minimal evidence of lowland Classic Maya influence. In contrast, within the Cancuen epicenter itself, highland style ballcourts, cave shrines, and ceramics suggest eighth century adoption of aspects of highland ideology and ritual, perhaps as elements of elite strategy. This interregional boundary pattern contradicts intuitive and traditional (and most “World System”) conceptions of interaction between highly complex state societies and less complex neighbors. However, recent more sophisticated models view borders or boundaries as dynamic zones of networks of interaction between individual or group agents. Such networks are posited for the Cancuen region, directed by elites with specific, identifiable, economic and political agendas.

[302]  **Ancient Maya Settlement Studies in the North Vaca Plateau, Belize**

Although numerous archaeological investigations focusing on ancient Maya settlement patterns have fostered considerable insights and knowledge, important questions remain regarding the circumstances in which these settlements originated, interacted, developed, and were ultimately abandoned. Exploring the configuration and growth of individual settlement units and their dynamic involvement and influence within the greater settlement continuum over time is essential to improving our knowledge of ancient Maya sociopolitical and socioeconomic interactions, human-environment adaptive strategies, and the circumstances surrounding the Classic period “collapse”. The Social Archaeology Research Program has been conducting multi-scalar settlement studies within the North Vaca Plateau of west-central Belize for several years. One such study has incorporated the analysis of three different settlement zones including the epicenter of Waybil, a minor center, its peripheral settlement units, as well as various settlement units located within the nearby Contreras Valley. In doing so, the project has accumulated large amounts of data pertaining to several levels or scales within the greater settlement continuum. These investigations have resulted in the collection of valuable data that is both diachronic and diverse in nature providing information regarding the development and patterning of ancient Maya settlement within the Vaca Plateau micro-region.

Dempsey, Erin (National Park Service, Midwest Archaeological Center) and Rolfe Mandel (Kansas Geological Survey)

The Cramer endowments have provided considerable support for using geoscientific methods in the search for the material remains of the first Americans. Investigations at sites in the Great Plains and Midwest, including Kanorado and Coffey in Kansas and Big Eddy in Missouri have demonstrated that building landscape-level models of geologic preservation potentials is a critical component of that search.
This approach has proven exceptionally useful in the Ozarks of southeast Missouri where decades of research in the Current River valley have demonstrated the complexity of the archaeological record. Patterns of landform use through the history of human occupation are elusive in this part of North America, a problem mostly attributed to the dynamic nature of Ozark streams, and the Current River is no exception. With support from the Odyssey Archaeological Research Fund established by the Cramers at the University of Kansas, a research program was undertaken to determine the numerical chronology and soil-stratigraphy of alluvial landform sediment assemblages (LSAs) in the Current River basin. From these data, a landscape-based predictive model was developed to target LSAs that may harbor Paleoindian and earlier cultural deposits.

Examining DINAA’s potential to reframe our archaeological vocabulary

State Historic Preservation Offices (SHPOs) each maintain their own independent archaeological site databases. This can result in states utilizing different language to describe similar sites, imposing modern political boundaries on our understanding of the past. This poster examines how archaeological vocabulary is implemented across state lines, and explores how a supplementary structure - such as the Digital Index of North American Archaeology (DINAA) – can be used to help interoperate divergent systems. DINAA’s multi-state approach offers North American archaeology a chance to develop a more standardized vocabulary that can evolve nimbly with user input, but that interoperates with legacy terms so that professionals can recognize and query concepts that relate to those in their local terminologies. Because it has the potential to both ‘translate’ our past work and update our terminological framework, SHPO databases can be better interopereated across state lines with derivative benefits in multi-state research. DINAA is an ongoing project that seeks to organize archaeological data from multiple states within a common online architecture. Because DINAA is public, it only hosts non-sensitive information, and exists to supplement (not replace) the current data management systems maintained by the SHPO offices in each state.

Dennehy, Timothy and Jacob Harris

Australian and Californian Tribal Area as a Function of Coastal Proximity and Mean Annual Precipitation

Predictable resources are crucial to hunter-gatherer subsistence. An increase in resource density and predictability can lead to an increase in population density and boundary defense (Bowles and Gintis 2011). Since coastal environments can offer foragers unique access to densely distributed, predictable resources, we hypothesize that population packing would lead to smaller tribal territory size in coastal areas. To investigate the effect of resource density on tribal boundary size, we compared the effect of coastal proximity to that of mean annual precipitation (MAP) for two ethnographically-known tribal regions—aboriginal Australia (n = 594 tribes) and pre-contact California (n = 100). We digitized maps from Tindale (1974) and Kroeber (1922) using updated GIS methods. Each territory was digitized in ArcGIS and precise numerical data extracted. Our preliminary results suggest that coastal proximity explains little of the variation seen in Australian and California tribal boundary size, while MAP accounts for a much greater percentage of the variation. Interestingly, there is a greater correlation between MAP and inland territory size than between MAP and coastal territory size. This study reveals that, although variation in Australian and California tribal territory size can be partially attributed to coastal proximity and MAP, much of the variation is yet unexplained.

Dennett, Carrie (University of Calgary)

Getting to Know You: Ceramics and Identity in Greater Nicoya

Iconographic analyses of ceramics from Greater Nicoya have traditionally focused on aspects of change related to external cultural influences (ca. A.D. 500–1500). Attempts to correlate ethnohistoric accounts of in-migration with typological developments seen in the archaeological record have resulted in a strong focus on the impact of Mesoamerican cultures. This paper, however, takes a different approach, looking instead to flesh out aspects of continuity in tradition within that change in an effort to better understand
more nuanced aspects of identity in this highly complex archaeological region.

Dennison, Meagan (University of Tennessee, Knoxville), Lucinda Langston (East Tennessee State University), Jay Franklin (East Tennessee State University), Jeffrey Navel (East Tennessee State University) and Sierra Bow (University of Tennessee, Knoxville)

We combine multiple lines of evidence to examine archaeological data from 17 years of archaeological surveys and excavations on the Upper Cumberland Plateau (UCP) of Tennessee. We focus on the Late Archaic and Woodland periods. Historically, this area, like many highland regions, has been underrepresented in archaeological research. Ideas regarding practices in highland regions have been oversimplified, if addressed at all. We have sufficient data to explore the prehistory of this region using a chaîne opératoire approach, one through which we can adequately address human agency and practices in highland regions. Toward this end, we employ a variety of analytical techniques including GIS modeling, optimal foraging strategies along with traditional faunal, lithic, ceramic, and botanical analyses. Prehistoric peoples targeted certain resources on the UCP but in myriad ways which defy more conventional processual approaches to North American hunter-gatherer studies.

Dennison, Rory (University of Illinois at Chicago)

[235] *Preliminary Analysis of Sourcing Philippine Porcelain to Southern Chinese Kiln Sites Using LA-ICP-MS*

Long distance, maritime based exchange between mainland imperial powers and island Southeast Asia has had a defining effect on the modern, global world even in periods prior to colonial presence. Porcelain serves as a good indicator of these exchange routes due to both its high durability and its prevalence in the archaeological record as well as its use as a marker of status, legitimization, and elite power. This research examines the network of long distance trade between southern China and the Philippines which existed in the tenth to fifteenth centuries through the use of Laser Ablation Inductively Coupled Plasma Mass Spectroscopy (LA-ICP-MS) to distinguish patterns, examine ceramic homogeneity across the sites and regions, and begin to source porcelains to kilns of production. Porcelain and tradeware from three Philippine sites are considered and compared to chemical data from clay associated with kiln sites in Fujian, China. Though preliminary in nature, this research outlines the potential a multiscalar and chemical analysis approach can bring to bear on the issue, highlighting results which indicate economic variability in porcelain groups across regional and sociopolitical integration.

Derbyshire, Sam (University of Oxford)

[186] *Turkana Past and Present: Tracing Change with the People of the Grey Bull*

This paper explains on-going archival, historical, and ethno-archaeological research currently being conducted with pastoralist Turkana communities in North-western Kenya. At the core of this on-going research is a novel approach to pastoralist material culture systems, which aims first at constructing a material culture history and then using that history to contextualize a contemporary ethno-archaeological investigation. The overall purpose of this research is to create a diachronic picture of material culture development that integrates the historical past with the present. The last century of material culture development in Turkana is explored through an integrative analysis of documents and photographs currently stored in Rhodes house and the Pitt Rivers museum, Oxford, alongside previous ethnographic, historical and oral-historical research dating as far back as the 1950’s. Through the analysis of these combined data it is possible to trace changes to Turkana material culture over the last century and explore the way in which material culture has been, and still is implicated in processes of community change. Analyzing how and why material culture has changed over the last century within this pastoralist community raises important questions relating to the broader archaeological analysis of pastoralist sites and periods.

Des Lauriers, Matthew (California State University, Northridge)

[282] *Degrees of Separation: Desert Islands as Remote Landscapes*

Remoteness and isolation are two terms that are quite frequently applied to island settings. While some, such as Easter, can be characterized in no other way, others are parts of complex networks of regional economic and political interaction. The Aegean Islands, the Caribbean Antilles, and others are powerful exemplars of these latter situations. How and where can we see the distinctions between isolated versus integrated systems? Societies which occupy geographically remote landscapes may not necessarily be
isolated socially, while they may display significant self-sufficiency in their economic system. How can we measure these concepts in anthropologically significant ways, and how did people who found themselves in such situations behave in unique and distinct ways from those populations occupying locales more intensively integrated with neighboring regions? The case of Isla Cedros, Baja California provides an excellent example of a geographically isolated population, which though remote from other relatively dense population centers, managed to develop both sustainable and dynamic patterns of human ecology and social organization. This remote Baja California island challenges some common assumptions about island hunter-gatherers, while demonstrating ways that archaeology can engage with larger discussions of human and political ecology.

[64] The Walking Dead: Establishing and Maintaining Community in Northern Albania

While bioarchaeology and mortuary analysis are inextricably woven into the study of past populations, the modern communities in which we work also provide valuable information and insight into the complex relationships between past and present. The ebb and flow of population movement, both past and present, has an effect on community dynamics and social relationships. The northern Albanian city of Shkodër is thus an ideal testing ground for examining the social changes that accompany the regional movement of both people and things – particularly since people have been settling and re-settling the area since the Early Bronze Age (ca. 3000 B.C.), when the sudden emergence of tumulus (mound) burial changed the way people disposed of (at least some of) their dead. When subjected to micro- and regional levels of analysis, these burial mounds – which are found throughout the northern Albanian landscape – can inform us about how continuities and/or changes in social relationships are reflected in (and by) their incorporation into living communities, both past and present. Spatial and temporal relationships between tumuli and settlements will be presented, in conjunction with an overview of how present communities incorporate these features into their social systems.

[183] Kanukaski (I Am Scratching It): Examining the Artifacts of Native American Body Art in the Eastern Woodlands

Prior to removal and acculturation, Native American societies in North America’s Eastern Woodlands engaged in a number of forms of indigenous body art, including both tattooing and scratching. The prevalence and cultural importance of these practices are documented in ethnohistorical and ethnographic literature from the region, and their antiquity is reflected in prehistoric human figural art. Nevertheless, archaeological identifications of tools used for tattooing and scratching have been sporadic prior to the last decade. This has likely been the result of reliance on traditional artifact typologies and cultural bias or academic misunderstanding regarding tattooing and indigenous body art. This paper discusses ongoing efforts to identify artifacts associated with ancient Native American tattooing and scratching in the Eastern Woodlands, and particularly within Tennessee and the Southeast. This work includes a combination of ethnoarchaeological and ethnohistorical research, experimental archaeology, use-wear analysis, and a reassessment of the appropriate archaeological context for successfully identifying these remains. These studies contribute to our growing understanding of the significance and antiquity of ancient Native American body art.

[285] Investigating the Ancient Elite of Panquilma’s Public Sector

Panquilma is an ancient Ychsma habitation site on the Central Coast of Peru. It rests in the Lurin River
Valley region, approximately 30 km east of Pachacamac. The site of Panquilma is divided into three sectors. Sector 1 is the sector we are focusing on for our paper; it is considered the public sector and includes three pyramids each with a ramp, as well as storage rooms and a few dwellings. The purpose of this study is to analyze the two funerary contexts in Panquilma’s Sector 1, Unit 10 which were excavated in June of 2013. It is important to note that most found human remains in Panquilma are part of the funerary cists in Sector 3, however the 5 individuals we excavated were found in a public sector that is also associated with the storage of the elites. The individuals range in ages and contain both sexes. Analyzing the material remains, both artifacts and ecofacts, the funerary contexts, the positioning of the individuals, the types of burials, and identifying the individuals’ sex and age will help us to better understand the elite who were buried here, and possible rituals and ideology during ancient Panquilma.

DeWitte, Sharon (University of South Carolina) [102] The Aftermath of Catastrophic Mortality: Physiological Stress, Stature, and the Effects of the Black Death

The 14th-century Black Death was one of the most devastating epidemics in history. Previous bioarchaeological research has shown that it targeted frail individuals and therefore might have strongly shaped patterns of demography and health in the surviving population. There is also historical evidence that standards of living, including diet, improved dramatically after the Black Death, and such changes might also have affected health in the post-Black Death population. Previous research has indicated that following the epidemic, mortality rates were lower and greater proportions of people survived to later adult ages than was true before the epidemic. This study examines temporal changes in stature to evaluate the effects of the Black Death on health using a combined sample of 194 individuals from several London cemeteries that date to just before (c. 1000-1300) and after (1350-1538) the Black Death. The results indicate that males were significantly taller following the Black Death; however there was no significant difference in mean height for females before and after the epidemic. This might indicate better physiological buffering of females before the Black Death or that females experienced improvements in diet to a lesser extent than did males after the epidemic.

Dexter, Jaime (University of Oregon), Chantel Saban (Oregon State University) and Tara McCaffrey (Linfield College) [148] Assessing Late Pleistocene/Early Holocene Diet Breadth in the Northern Great Basin through Paleoethnobotanical Analysis— A Few Details to Consider before Committing to the Paleo Diet

The archaeological deposits at Oregon’s Paisley Caves (35LK3400) contain key information about the foraging behaviors of late Pleistocene/early Holocene people in North America due to the record of human occupations at the site dated as early as 14,290 cal yr B.P. The antiquity of cultural deposits and the fine resolution of the micro-stratigraphy provide a unique opportunity to reconstruct a record of anthropogenic plant use in the northern Great Basin during the terminal Pleistocene and early Holocene (ca. 14,000-7,600 years B.P.). Macrobotanical data from LP/EH cultural deposits preserved in Cave 2 deposits document the relative importance of plant resources, and the quantification of botanical remains demonstrate the relative importance of various plants in cultural practices. Morphological seed characteristics and statistical analyses are used to distinguish seeds and charcoal deposited by humans from those deposited by nonhuman predators and scavengers. Results are analyzed within a framework of known climate oscillations along with a local pollen record in order to better understand human-environmental interactions during this time.

Diaz, Alejandra, Anna Marie Prentiss (University of Montana), Olaf Nehlich (University of British Columbia) and Michael Richards (University of British Columbia) [175] Diet and Mobility on the Canadian Plateau: Isotopic Analysis of Canids and Other Fauna from the Bridge River Site

This study reports on carbon, nitrogen, and sulfur isotope analyses of dog remains and other fauna from the Bridge River site in the Mid-Fraser region of the Canadian Plateau. We discuss these results in relation to dietary variability, resource mobility, and human-dog interaction through time. While dogs are not a direct proxy for humans in dietary isotope studies, their diets are influenced by human dietary practices, and therefore indicative of human subsistence strategies and activities. Similarly, evidence of
dog mobility reflects the spatial interactions between human groups and resources. Dietary results demonstrate that while salmon played an important part of dog diet at Bridge River, variability occurs across age groups and culture periods. Mobility results demonstrate differences between individual dog values, indicating the mobility of dogs and potential differences in origin through time.

Urnas del Candire

La práctica de entierro en urnas por parte de los pueblos prehispánicos fue registrada en el noroeste Argentino por las fuentes etnohistóricas y luego corroborada mediante las investigaciones de la arqueología. A partir de un rescate arqueológico realizado en el norte de Salta, el aporte de la etnografía permitió conocer los relatos orales corroborando que esta modalidad de entierros en urnas perdió hasta tiempos muy próximos a la actualidad. La permanencia de este tipo de prácticas, cientos de años después de la conquista, asociados a una particular concepción de la vida y la muerte, permiten reflexionar acerca de los procesos culturales y la construcción de identidades en los pueblos aborígenes e implica el desafío de la restitución de los restos a la comunidad, según lo acordaran en el año 2010. El hallazgo, por estar relacionado a una cultura viva permite asimismo realizar un abordaje conjunto entre la antropología y la arqueología, dado que las autoras han realizado diversos trabajos y talleres de recuperación del patrimonio en estas comunidades, principalmente en sus expresiones artísticas distintivas desde el año 2004 en adelante y son las únicas comunidades Chané de la Argentina, hecho que incrementa su singularidad.

Marvin Rowe and the Missouri Pictographs

Marvin Rowe’s work on a sample of Missouri pictographs opened new windows into the past by shedding light on symbols previously dated only by stratigraphic association. Radiocarbon determinations demonstrated the pigments to be ca. 1000 years old. Hence, they are significantly earlier than previously thought to be the case. Rowe's research is a major contribution to the study of ancient pictographs, a long-neglected aspect of Eastern Woodlands archaeology. Although his contributions to numerous interdisciplinary projects are highly significant, my discussion here centers upon Marvin Rowe's ground-breaking work on the Missouri pictographs.

Fishing and Land Use: What Studies of Fishing Technology and Topography Can Tell Us about Prehistoric Land Use

Barbed harpoon points manufactured from bones are found around the Lake Turkana basin in Kenya and Ethiopia. A laboratory study of the characteristics of these harpoons has been conducted and harpoon characteristics vary geographically and temporally. Changes in the Holocene landscape particularly variation in the lake levels of Lake Turkana have occurred and models of these changes has been constructed. This paper looks at the quantified assemblage variation of bone harpoons and other archaeological materials in relationship to the hydrological changes and the lake level models of the Lake Turkana Basin. The landscape models created using high resolution topographic data coupled with archaeological data are used to illuminate and explore landscape use by fishing people in the Turkana Basin and then is compared to landscape use of people with differing economic strategies, specifically hunter-gathering and pastoralism. This paper will show how the use of artifact databases can be used to refute or validate models of prehistoric land use.

DiBenedetto, Katelyn (University of Nevada Las Vegas)

Ais Giorkis: The Last Refuge for Cattle on Cyprus?

Ais Giorkis, an early Neolithic site (ca. 7800 cal B.C.), is one of only three sites on Cyprus dating to the
Neolithic with cattle remains. It currently appears to be the latest of these sites, and the only one located in the uplands. Cattle disappear completely from the island by the later Neolithic and are not reintroduced until approximately 4000 years later. Thus, their presence at Ais Giorkis raises numerous questions, in particular: was this site the last refuge for cattle on Cyprus? Excavations are ongoing, and this is the beginning of a study that examines the role of cattle at the site, including whether they were for subsistence and/or used as status markers. This study will document their spatial distribution to determine if they cluster near the tentatively identified domestic structures and their relationship with other faunal materials. The results will be compared with the other early Neolithic sites to see if all three cattle populations fulfilled the same role and whether this role could be occupied by other animals. This will determine if their disappearance was ultimately tied to the formation of an island-wide identity and whether Ais Giorkis was the last refuge for cattle on Cyprus.

Dickson, D. Bruce (Texas A&M University)

Kingship as Racketeering: The Royal Tombs and Death Pits at Ur, Mesopotamia Reinterpreted from the Standpoint of Conflict Theory

The interpretation of the Royal Graves and Death Pits at Ur, Mesopotamia by their excavator, Sir Leonard Woolley (1934) has long been accepted. Woolley concludes the people sacrificed along with these putative dynasts went willingly to their deaths out of loyalty, devotion and faith in their dead monarchs. But other interpretations are plausible. Conflict theory, presumes that profound inequalities in power exist between and within social systems. In Conflict theory, the primary role of the state is to maintain the dominance of one segment of society over the others. Conflict theory is used to reinterpret Ur’s kinship and state to suggest these institutions constitute a kind of racketeering. Ur’s kings may indeed have been strong and their subjects loyal, but it is equally likely that they were weak and vulnerable and that they practiced ritual sacrifice to terrorize a restive citizenry in order to maintain elite dominance over society.

Diederichs, Shanna (Crow Canyon Archaeological Center) and Scott G. Ortman (University of Colorado)

The Invention of Community in the Mesa Verde region

A range of evidence suggests that the Mesa Verde tradition formed through the interaction of local foragers and immigrant farmers during the early centuries A.D. New archaeological evidence suggests that local foragers already had a tradition of periodic group assembly at open-air dance circles. As farming was adopted, new social problems related to land tenure and private property required new social institutions, the invention of which is reflected in changing forms of public architecture and social organization, especially the replacement of dance circles by great kivas, and the emergence of episodic community organization in the 7th-century A.D. These changes suggest that, as Pueblo ancestors adopted farming from other peoples, they also invented the social institutions needed to support a Neolithic lifeway. These institutions characterized the Ancestral Pueblo world for the next 600 years.

Diego Luna, Laura

Ornamentación, poder y cosmovisión en el palacio de Yucundaa

En esta ponencia se describen los elementos arquitectónicos que decoraban los edificios del palacio de Yucundaa, la sede del poder de un importante señorío mixteco del periodo Posclásico Tardío. Los edificios que componen este complejo arquitectónico tuvieron una decoración consistente en mosaicos y relieves de piedra, estos últimos en el estilo artístico conocido como Mixteca-Puebla. Pese al estado fragmentado de los relieves, podemos inferir que el conjunto de la ornamentación de estos espacios se relaciona con aspectos de la cosmovisión mixteca y la legitimación del poder de los grupos que los ocuparon.

Diehl, Michael

Paleoethnobotany of the Harris Village

Recent excavations at Harris Village led by Barbara Roth at University of Nevada Las Vegas resulted in the systematic collection and analysis of 102 flotation samples. The effort accords the first opportunity to fully examine the use of food and medicinal plants from that site, despite its seminal role in the definition of the Mogollon Culture by Emil Haury in the 1930s. Of food consumption at Harris Village, in the late
1930s, Emil Haury wrote that charred maize had been observed, and beans and squash were absent. Modern excavations have, however, yielded both maize and beans, and more than 14 wild plant seed or propagule tissue taxa. This presentation provides a summary of the identified food and medicinal plant taxa and their ubiquities in the Harris Village assemblage, and identifies arenas of ongoing analyses at Harris Village and other Mimbres pithouse villages.

Aging in Place While Running to Keep Up: Some Thoughts on the “Golden Marshalltown Years
As Baby Boom archaeologists approach retirement, how might they remain productive in the “Golden Marshalltown” stage of their careers? This essay examines what some of their illustrious predecessors have done, and what they might do in the emergent digital and post-processual stages of the discipline. It opens with an examination of the post-employment careers of four eminent Mesoamericanists, Alfred V. Kidder, Gordon R. Willey, Richard S. MacNeish and William T. Sanders. The focus then shifts to opportunities available to Dan and his contemporaries. These include writing up unfinished research, crafting memoirs, proselytizing archaeology, research in museum and other curated collections, and seizing the endless opportunities the World Wide Web offers for disseminating their thoughts without having to worry about salary increases, tenure decisions, and other parochial academic concerns. In closing, I suggest steps universities, museums and other organizations can take to facilitate the process while reaping an inexpensive bounty; including the provision of office space, secretarial assistance, informal teaching and mentoring opportunities, and similar incentives.

Dietler, John, Benjamin Vargas (SWCA Environmental Consultants) and Jim Potter (SWCA Environmental Consultants)

Parece Razón: Evidence for Native Americans at Mission San Gabriel, California
Parece razón: an unusual annotation in Mission San Gabriel’s baptismal register indicating that an infant of unknown parents appeared to be ethnically Hispanic. This term may be applied to the mission’s archaeological materials as well. Historical data indicate that Native Americans were key members of the mission community, representing the great majority of the population, the providers of virtually all labor, both skilled and unskilled, and primary consumers of much of the mission’s products. Why is it, then, that the material culture of the mission’s archaeological site does not display more traditional Native American characteristics? Data recovery excavations within the site’s garden area have recovered a substantial artifact assemblage that is dominated by European-style objects, both imported and locally made. Non-traditional and traditional Native American goods are present, but less common. Dietary evidence is also heavily skewed towards introduced domesticates, and most identified archaeological features, with one notable exception, represent Euroamerican-designed buildings. We explore several possible explanations, including intrasite sampling bias, the greater visibility of younger deposits, the material impact of San Gabriel’s tremendously successful cattle industry, and the differences between European and Native American material practices that may have resulted in different degrees of archaeological visibility.

The Transnational Market in Illicit Archaeological Antiquities: Preliminary Findings of a Comparative International Study of Governance and Control
This paper discusses the preliminary findings of a comparative international study of governance and control in the transnational illicit archaeological antiquities market conducted over the last year.

Diez-Martin, Fernando

Anticipating the Levallois Concept? Revisiting the Bifacial Hierarchical Centripetal Exploitation Model in the African Early Acheulean
Predetermination of flaked products has been considered a hallmark of complex cognitive skills in human evolution. Traditionally, the landmark of this complex way of knapping stone artifacts has been the Levallois technique. The lithic assemblages from Lake Natron (Tanzania) have been used to argue that
predetermination of the flaked products was observable in East Africa during the Early Pleistocene. Through the use of the so-called bifacial hierarchical centripetal exploitation model, hominins would have hierarchically planned the whole series of knapping steps and would have carried them out successfully until core exhaustion and discard. This reduction model would constitute a significant technological trait intimately linked to other volumetric advances characteristic of the Early Acheulean technology in East Africa. Acknowledging that the verification of the hypothesized model would constitute a significant paradigm turnover, this contribution aims to present a reevaluation of the bifacial hierarchical reduction model and its implications for the evolution of technological behaviors based on archaeological and experimental data.

[245] An Early Andean Enigma: Huaca Prieta, Peru, Research and Meaning

Huaca Prieta is a large, complex mound site on the north coast of Peru that dates from ca.14,500-4,200 cal B.P. Interdisciplinary research at and around the site reveals a series of stratigraphic, artifactual, and architectural traits that do not fit within known or expected Andean patterns. The site is not only an anomaly in western South America and perhaps beyond, but is also anomalous with regard to other regions of the Americas. The broader social, economic, ideological and ecological implications of the findings to date are discussed from theoretical and culture historical perspectives.

[249] Holocene Obsidian Use in Northern Kenya

The Turkana Basin, with a long antiquity of human occupation offers a unique laboratory for examining changing patterns of lithic material procurement and use through time. Though there remain many undocumented and uncharacterized sources of obsidian in the region, preliminary studies, by us and others, have already demonstrated that early Holocene hunter-fisher-gatherers began exploiting regional obsidian sources, and by the middle Holocene, early pastoralists used this material extensively. Analyses of Kenyan obsidian sources are revealing patterns of obsidian procurement and use that mark changes in subsistence and mobility. As we begin work investigating early Holocene obsidian use we hope to identify new patterns and sources that were used by prehistoric people. This paper provides an overview of research to date.

[242] Spatiotemporal Rainfall Variation in the Leeward Kohala Field System: Implications for Prehistoric Hawaiian Agriculture

Pacific Island agricultural research has focused predominately on measuring the degree of uncertainty in dryland subsistence practices. Environmental risk and uncertainty have been especially important topics in the Hawaiian Archipelago, specifically in relation to the large dryland agricultural systems of Maui and Hawai‘i Island. Unlike most windward agricultural systems, leeward dryland agriculture was almost completely dependent on rainfall. It is generally assumed that dryland field systems were highly susceptible to droughts, potentially resulting in food shortages with various societal consequences, such as conflict and the emergence of social complexity. The recent publication of the Rainfall Atlas of Hawai‘i enables us to build more fine-grained models of spatiotemporal rainfall variation in the Hawaiian Islands. Using this newly published rainfall archive, we investigate spatiotemporal rainfall patterns on Hawai‘i Island, with particular emphasis on the Leeward Kohala Field System (LKFS). We employ geostatistical modeling techniques and time series analyses to quantify the amplitude and periodicity of droughts in the LKFS and discuss the implications of our results for Hawaiian agriculture and emerging sociocultural patterns.

[244] Human-Environmental Interaction in a Pleistocene Coastal Environment: Research Strategies for Stone Artifact and Molluscan Assemblages from Boodie Cave, Barrow Island

In Australia, as elsewhere, coastal Pleistocene sites are relatively rare. As a consequence, Pleistocene human-environmental interactions in maritime environments are poorly understood. The relative importance of maritime resources on proximal coastal plains during fluctuating sea levels is even less well described – though models for coastal productivity during the last 50,000 years are being proffered. Barrow Island, located in northwestern Australia, retains a coastal archaeological landscape (a veritable ‘time capsule’ dating to pre-7,000 B.P.) consisting of both open and stratified contexts which may date back to pre-40,000 B.P. One stratified context, Boodie Cave (J08-001), preserves a deeply stratified sequence which includes multiple phases of both stone artifact and molluscan assemblages. These assemblages provide a unique opportunity to investigate patterns relating to human-environmental interactions during the Pleistocene. This paper will outline proposed research strategies for analyzing both the molluscan and stone artifact assemblages. Some preliminary results are presented.

[21] A Site in Motion: Examining Intrasite Mobility at Cerén, El Salvador

The Classic Maya site of Cerén sits in the shadow of a chain of volcanoes in western El Salvador. Not once, but many times, eruptions have caused residents to hastily vacate the area, only for others to return at a later point in time. In addition to movement in and out of the region, mobility at Cerén is detectable from household to household and in artifact assemblages that contain trade goods from near and far. Variation in the material record may further our understanding of how individuals, even within the same community, differently participated in socioeconomic spheres. The detailed preservation of the site beneath multiple meters of volcanic ash affords the rare opportunity to assess mobility at a micro-scale within the site. The surprising discovery of an earthen sacbe in 2011 indicates a directed and formally constructed flow of traffic. Additionally an analysis of structure orientations and open spaces within and around the site center allow for an evaluation of how and where individuals would have most readily traveled. Cerén provides the opportunity to assess the flow of peoples, ideas, and material goods within and beyond the site core.

[3] Caught by the Coiffure! Subordination, Ceremony and the Significance of Hair among the Classic Maya

Hair is unique in the study of dress—it is simultaneously part of the human body and a component of apparel as transformable as any garment. In this paper, I describe patterns and spatiotemporal variation in Classic Maya depictions of coiffure on monuments, murals and vessels. I argue that hair was considered deeply personal by the ancient Maya, and was only displayed in limited contexts, most often to indicate captivity, subservience, or intimacy between participants in ritually charged events. My approach, like the others in this session, treats hair as one component in broader representational ensembles, emphasizing how it articulates with accompanying elements of dress and depicted scenes. In addition to this synthetic typological approach, I consider the settings where the Classic Maya deemed the display of hair appropriate, and when they instead chose to keep it obscured by other pieces of apparel. To explain their conservative treatment of hair, I close with an analysis that draws upon a range of archaeological, ethnohistoric and ethnographic data from throughout Mesoamerica. This work serves to improve our understanding of the Maya sense of body and representation, while providing a new case study in the anthropology of hair.

[257] Surveying through the centuries: The Amuq Survey in Context

The Amuq region of Turkey has been an object of inquiry since the 1930s. This research exposed the nature of, and possible motivations for, ancient human exploitation and transformation in a complex mountain-walled valley near the Mediterranean coast, through which three rivers flow seaward to ancient ports near modern Antakya/Hatay (ancient Antioch). The recent survey (2009-2012) targeted the northernmost portion of this valley, which lies roughly 70 kilometers north of the Bronze and Iron Age
palace towns, Alalakh (Tell Atchana) and Tell Tayinat, in an area not intensively investigated previously. U. Bahadir Alkim carried out research in this part of the valley in the mid-20th century. His data constitute an important companion to the most recent work and are considered in tandem. The diverse thematic interests and methodological approaches employed in the Amuq Valley Survey created noteworthy impacts in the data set, which are relevant to understanding what changes occurred and when. The types of sites and time periods discovered over time have varied considerably. Significant changes to settlement organization in the Amuq are evaluated in relation to developments in adjacent areas, and their visibility in comparison to historically-attested changes known from sources relevant to this region.

Dodge, Robyn (The University of Texas at Austin)

Hun Tun: Home to Social Complexity in the Hinterland

Ancient Maya household archaeology has recently been focused on understanding ordinary people, understanding social diversity amongst households and understanding households in articulation of the greater social universe. Household identity among ancient Maya commoners serves as the prominent theme of this talk. Maya Household archaeology provides a platform for inquiry into every social actor of Maya civilization. Therefore household oriented studies are applicable to every context of ancient Maya life. As physical dwellings, the material culture from household assemblages provides insight into how households constructed a social world. This is achieved through the expression of ritual, production, socialization and exchange. Households serve as microcosms providing insight into larger social processes operating within complex civilizations. Ancient commoners and their households constitute the bulk of Maya civilization. The Maya site, Hun Tun is located in northwestern Belize on the Programme for Belize Property. Hun Tun is a modest, commoner Late Classic Maya community with multiple household groups. Research at Hun Tun focuses on a household oriented study examining how households contribute to ancient Maya social complexity. This paper discusses information pertaining to Maya hinterland complexity at the household level.

Doelle, William (Archaeology Southwest)

The Mimbres Foundation in the History of Nonprofit Archaeology

The history of American archaeology has been shaped in substantial ways by nonprofit organizations. This paper reviews the role of nonprofits in a national context and in greater detail within the American Southwest. Finally, the role of multiple nonprofits within the Mimbres region, with a focus on the Mimbres Foundation, is explored. Nonprofits have historically shown bold and impactful innovations and accomplishments under the leadership of their initial founder(s). Nonprofits provide opportunities that are exemplified by the Mimbres Foundation: private fund raising, institutional agility due to minimal bureaucratic constraints, and potentials for partnerships. Creating an institutional context that can carry forward under new leadership is particularly challenging for nonprofits. Despite the fact that the Mimbres Foundation board of directors chose to close down this nonprofit, the legacy of the foundation is substantial. The highlights of that legacy are reviewed and the future of nonprofits in the Mimbres region is considered.

Alaskan Subsistence Hunting as an Ethnoarchaeological Resource

The passage of the Alaska Native Claims Settlement Act (ANCSA) in 1971 guaranteed Alaskan's legal rights to practice subsistence lifestyles. This presentation attempts to ascertain the degree to which Alaskans have been allowed to maintain a traditional subsistence lifestyle, despite legal restrictions and technological advances, and how the study of this lifestyle could further archaeological research in Alaska and around the world.

El Marquesillo: A Newly Recognized Olmec Center in Veracruz, Mexico

Investigations at El Marquesillo, on the banks of the middle San Juan River in southern Veracruz,
demonstrate that this settlement was an significant participant in the Early and Middle Formative period archaeological culture referred to as the Southern Gulf Coast Olmec (ca. 1250 to 400 B.C.). The site’s physical location fills a major void in the landscape of the Gulf Olmec Heartland, and the presence of a monumental Olmec throne, the results of geophysical surveys, and other lines of evidence suggest the settlement was a regional center during the Olmec period. The earliest demonstrable occupation at El Marquesillo is illustrated by Ojochi phase ceramics (ca. 1500-1350 B.C.), followed by Bajío, Chicharras, and San Lorenzo phase wares. Unlike most other Mesoamerican Formative period settlements, however, El Marquesillo exhibits a consistent occupation through the Late Classic Villa Alta phase (ca. A.D. 500-1000) and beyond. The data from this study provide new insight into the development of Formative period sociopolitical interaction. Thus, the settlement’s presence and probable effects on other contemporaneous sites require that El Marquesillo be considered in any discussion of the Olmec phenomenon.

I-SitesGov: Expanding Access to the Iowa Site File for Project Planners

I-SitesGov is a newly available controlled-access GIS website that broadens access to the Iowa Site File (the database of recorded archaeological site locations in Iowa). Subscribers are federal, state, county, and local officials and consultants who do not meet the professional archaeological standards necessary to access I-SitesPro but who need an enhanced level of data for CRM planning and consultation beyond what is accessible to the general public via I-SitesPublic. I-SitesGov provides users with map-based counts of recorded archaeological sites per quarter-section and includes a shapefile layer that illustrates areas previously subjected to archaeological investigation. These data—counts and survey coverage—serve as important compliments to the types of data available through additional sources and allow better informed and more specific decision-making about potential project effects. Additional data layers are planned such as burial project information. Links to other data sources to add georeferenced layers like aerial photography, LiDAR, and soils will be incorporated to further assist in identifying and expediting the need for hiring professional CRM consultants and assisting federal agencies in completing their compliance reviews. The I-SitesGov portal includes live hyper-links to referenced websites and an online tutorial.

Settlement History and Economic Practice at a Late Holocene Fisher-Hunter-Gatherer Village in the Southern Gulf Islands of British Columbia, Canada

Explaining the later Holocene evolution of fisher-hunter-gatherer societies of the Pacific Northwest requires that, alongside households and regional networks, we understand the histories of specific communities. This meso-scale approach contextualizes household social and economic strategies, and, where it has been applied on the Fraser Plateau and lower Fraser Valley, has significantly contributed to explanations of changes in these strategies at the local and regional scale. On the southwestern coast of British Columbia, Canada, logistically organized fisher-hunter-gatherer populations moved into settled villages at least 2400 years ago, a facet of settlement systems that continued into the ethnographic period. The long-term research program at the Dionisio Point site for three seasons has targeted village-level historical process at this 1,500 year old village on northern Galiano Island. Here, we present the results of new radiocarbon dates and materials analysis that permit us to further refine the village chronology and examine intra-settlement historical variability in economic practice.

Past Perspectives and New Issues in Obsidian Sourcing in the American Southwest

Over the past 50 years, obsidian sourcing has influenced the way archaeologists view prehistoric trade, procurement, and social interaction through time and across space. The North American Southwest is one of the most studied geographic regions for obsidian because of the numerous sources available that yield high quality toolstone material. Although this region is known for its painted pottery and architecture, archaeologists are going beyond normative models of trade and exchange to gain more insight into Southwestern social complexity using obsidian sourcing data. In this paper, I provide an in-depth synthesis of obsidian sourcing studies across the Greater Southwest to explore a range of research topics that include ritual economy, long distance interaction spheres, and diachronic changes in obsidian procurement. As more obsidian data accumulates with the increasing availability of archaeological techniques, it is also important to discuss the pertinent questions for future research such as social
identity, memory, and cultural landscapes which will shed even more light on the dynamics behind southwestern prehistory.

Dollar, Nathanael

Intensification theory has been used by archaeologists to understand change in diet and subsistence practices. This theory proposes that changes in food production, including increased production, technological development, and even preferred subsistence methods, is determined by the population levels of a society. Lewis Binford (2001), using ethnographic case studies, built upon this work and formulated very specific predictions for change in diet and subsistence methods based on population densities. These predictions can be difficult to test archaeologically, however, due to uncertainty in use of food resources and the roles they played in diet. Coprolites from the Lower Pecos region of Texas provide a testable case study for the application of intensification theory. Due to preservation conditions, hundreds of coprolites spanning thousands of years have been excavated from latrines at rock shelter sites in the region. These coprolites provide an immediate, certain, and measurable account of what resources were used in the diet. They also allow evaluation of how resources were used and what proportions of the diet they composed. This presentation will examine the data from previously studied coprolites to examine diet change over time in the Lower Pecos and uses the results to evaluate Binford's intensification theory proposals.

[42] Abundance of Large Game and Source-Sink Dynamics in the Northern Rio Grande and Mesa Verde at A.D. 1300

Abandonment of the Mesa Verde region (ca. A.D. 1300) has preoccupied North American archaeologists for decades. However, little is known about what happened to the people of Mesa Verde after depopulation. The Northern Rio Grande (NRG) region of New Mexico is one of the areas Ancestral Puebloan people may have migrated to, as evidenced by an increase in population density in the area after A.D. 1300. Several migration pull factors may have drawn Mesa Verde people to the NRG, including abundant large game. To address this as a potential pull factor, we assess hunting efficiency using zooarchaeological data from three Mesa Verde Pueblo I-III (A.D. 750–1300) sites and two NRG sites (ca. A.D. 1300–1600). If the Mesa Verde region had become a faunal sink, then large game abundance should have been substantially higher in the Northern Rio Grande after A.D. 1300.

[200] Lithic Reduction Sequence in Hunter-Gatherers Sites of North Coahuila, Mexico

Lithic reduction sequence in hunter-gatherers sites of north Coahuila, Mexico.

In 2002, the archaeological project "Rio Escondido-Arroyo Coyote" was carried out in an area that includes the frontier zone in the states of Tamaulipas, Nuevo Leon, and Coahuila. The main reason for the salvage project was the imminent construction of an electric line for the area. The result of the project was the registration of 72 archaeological sites and 39 lithic distributions. Ten years later, employing a techno-morphological method to analyze the corresponding archaeological materials that were found and with the purpose of obtaining information on the manufacturing processes, from the procurement of raw materials to the different flaking techniques employed and the use, adaptation, reuse and discard of artifacts through time. In this paper, we present data from archaeological sites recorded in the state of Coahuila that fall into three categories: camp-workshop, procurement and ceremonial. Also, we describe lithic reduction sequences to establish their possible relationship with the functionality of the sites and the role it played in the study region.

ABSTRACTS OF THE SAA 79TH ANNUAL MEETING  192

Dongoske, Cindy (Zuni Cultural Resource Enterprise), T.J. Ferguson (University of Arizona) and Kurt Dongoske (Zuni Cultural Resource Enterprise)
[151]  Zuni and 40 Years of CRM: A Perspective from On and Off the Reservation
Cultural resource management legislation requires federal agencies to consult with Native American Tribes about places of traditional importance, ancestral archaeological sites, and the appropriate treatment of the physical remains of their ancestors. In 1975, responding to national legislation requiring the preservation of archaeological sites and other historic properties, the Pueblo of Zuni established its own archaeology program. Originally labeled the Zuni Archaeological Conservation Team, the Zuni archaeology program has evolved into the Zuni Cultural Resource Enterprise; a for profit cultural resource management enterprise of the Pueblo of Zuni. This presentation examines 40 years of performing cultural resource management on and off the Zuni reservation, evaluates the accomplishments and the difficulties associated with integrating Zuni traditional preservation values with the dominant Western perspective, and reflects on the persistent traditional cultural issues in cultural resource management.

Dongoske, Kurt (Zuni Cultural Resource Enterprise), Kelley Hays-Gilpin (Northern Arizona University) and Octavious Seowtewa (Zuni Cultural Resource Advisory Team)
[159]  Kwa Hoth Shiwi at Chama: Never Ending Zuni Presence on the Landscape
Zuni connections to their cultural landscape differentiates them from other tribal peoples and from the dominant colonialist society. What Zunis know about their cultural landscape flows from the “echo of generations,” and their knowledge cannot be universalized; it cannot be quantified scientifically, because knowledge arises from Zuni epistemological experience of landscape. We explain how Zuni concepts of space and time are integral to assigning meaning to places within the Zuni cultural landscape, contrast Zuni concept of time with the linear, measurable time concepts embraced by dominant Western society, and show how these dissimilarities contribute to clash of cultural values in resource management.

[204]  La piedra: un recurso multidimensional en la vida cotidiana del antiguo Carrizal, Veracruz
El Proyecto Arqueológico El Carrizal, Ver. (UNAM, UV, CONACyT) llevó a cabo, entre 2009 y 2011, un reconocimiento de superficie de cobertura total de alta intensidad en un area de 56 kilómetros cuadrados alrededor de la Villa Emiliano Zapata, Veracruz. Se identificaron 3,888 estructuras prehispánicas, así como se llevaron a cabo excavaciones intensivas y extensivas; las que determinaron una ocupación desde el Formativo Medio (800-400 a.C.) hasta el Posclásico Tardío (1325-1521 d.C.) El area de estudio cuenta con formaciones calcáreas del terciario marino, por lo que abundan las rocas como caliza, travertino y pedernal. Ademas, la cercanía con el Río Los Pescados otorga una amplia disponibilidad de rocas: cantos rodados de roca ígnea, sedimentaria y metamórfica, así como minerales como mica, pirita y cuarzo, entre otros. Esta ponencia aborda los diferentes usos de las rocas en la vida cotidiana, desde su empleo en las actividades domesticas, de producción, construcción, elementos arquitectónicos, escultura, etc. El objetivo principal de nuestro aporte consiste en la contextualización de la piedra como un recurso multidimensional integrado a la vida diaria de las poblaciones prehispánicas de la región.

Doolittle, William (University of Texas)
[237]  The Gristmills of La Orotava
The city of La Orotava on the island of Tenerife in the Canary Islands is home to the remains of an intriguing series of eight water-powered gristmills. Dating from the early colonial period, these mills are located within a city block of each other, and all relied on water from a single spring. The slope on which they were built is so steep that arched aqueducts were built from the canal that ran downslope, paralleling the present-day street, to the top of each millhouse. The arrangement of these mills is similar to the ancient ones found by James A. Neely on the Deh Luran Plain in what is today southwestern Iran. The mills of La Orotava, therefore, serve as a link in understanding technological transfers from the Middle East to Mexico.

[151]  The Two Greatest Business Challenges Heritage Consulting Firms Must Solve for Future
Success

Over the last 40 years, the business challenges facing private-sector heritage consulting firms engaging in cultural resource management (CRM) have changed. Most firms are currently faced with ownership/management succession, low return in value, insignificant market share, service communization, and high barriers to entry for a new generation of entrepreneurs. To achieve business success in the near future, private-sector heritage firms must respond to two major challenges: capitalization and differentiation. Capitalizing businesses is essential for their growth, competitiveness, scientific capabilities, and reaching key scales of efficiency. To capitalize, though, requires a change to the underlying business model that virtually all heritage consulting firms use. Differentiating between firms is the way to break the cycle of commoditization and raise firm value. Differentiation, though, is challenging because within the CRM regulatory environment it is extremely difficult to differentiate on scientific services: virtually all firms can perform scientific services at a high enough level to gain regulatory approval. Differentiation also requires a strong client orientation and many heritage firms have scientific agendas that don’t align with the needs or desires of their clients. While solutions to these two challenges will be varied, the near-future success of heritage consulting firms requires that solutions are found.

[295] Modeling Agricultural Potential in Chaco Canyon during the Bonito Phase: A Predictive Geospatial Approach

This study presents a geospatial analysis of Chaco surficial hydrology and geomorphology and their relationship to potential agricultural productivity in order to better understand the economic role of water in the Chaco Canyon during the Bonito Phase (ca. A.D. 850 to 1150). Defined as the Natural Agricultural Suitability Analysis, the foundation of this study is a hierarchical geospatial analysis that integrates six key natural factors: slope, soil texture, soil depth, non-catastrophic overbank flooding potential, drainage flow length, and drainage proximity and flow potential. These factors are combined through a raster weighted overlay function to generate composite suitability map that offers a testable proxy for variability in relative agricultural potential during the Bonito Phase at Chaco. The analysis is enhanced by a one-meter resolution LiDAR dataset. The rationale for including this set of natural factors is based largely on ethnographic and modern agricultural studies in Chaco, but the predictive model differs from previous studies of agricultural potential in that it is independent of the specific archaeological distribution of evidence of agriculture in the study area. The results of this analysis suggest that previous models of Chacoan agricultural productivity have underestimated local production capacity.

[172] Localizing Trends among Inland Drainage Systems: Connecting the Data in Northeastern Massachusetts

Recent archaeological investigations provide information that can be used to establish a current model of pre-contact exploitation of interior uplands in northeastern Massachusetts. This model refines conclusions drawn by Ripley Bullen more than 60 years ago about how settlement patterns, site distributions, responses to environment, technology for obtaining and processing resources (including food and lithic raw materials), and local variations in these patterns change over time. This poster explores trends in Native American utilization of the Shawsheen and Upper Ipswich drainage basins during the Archaic Period and how groups show a preference for carrying out most of their habitation and resource procurement activities on terraces near sizeable freshwater sources, including major rivers, tributary streams, and wetlands. This ongoing research contributes to our understanding of economic organization and relationships between temporary campsites, special purpose sites, and more permanent habitation sites within interior uplands.

**Human-Ratite Interaction in Antsaragnasoa, Southwest Madagascar**

The peopling of Madagascar is a rapidly evolving topic. New results from Lakatoni‘ Anja, a rock shelter in northern Madagascar, suggest that the date for initial human settlement may be pushed back to approximately 2000 B.C.E., 2500 years earlier than previously documented. Intimately linked to the questions surrounding the human colonization of Madagascar are hypotheses about the disappearance of the island’s megafauna and the role humans played in their extinction. Madagascar’s extinct megafauna include several species of ratites known popularly as elephant birds and classified into two genera, aepyornis and mullerornis. To date little direct archaeological evidence of human impact on elephant birds has been documented. This study investigates the relationship between human and ratite communities with survey and excavation data collected at several sites around Antsaragnasoa, a bay near the modern village of Andavadoake on the southwest coast of Madagascar. In particular, large quantities of eggshell fragments representing different ratite species are being analyzed and dated through a combination of techniques to answer questions about species diversity, paleoenvironment and human predation. Worked eggshell from excavated contexts lends fresh insight into the relationship between humans and the elephant birds through time.

**Households on the Social Landscape: A Perspective from the Southern Chuska Basin**

Households are fundamentally economic and social units. Many times conservative in their adaption to change, households are a unique laboratory for studying larger social, economic, and political trends in which they reside and interact. Households excavations dating between the Archaic through Pueblo III periods in the southern Chuska Basin, as part of the U.S. Highway 491 archaeological project, offer an important sample for understanding the relationship between households and dynamically changing larger regional political alliances, ceremonial spheres, and economic relationships through time. Public architecture and communal contexts suggest certain ties and trends for particular time periods. Do household excavations offer similar, or complementary, information? In this paper, we study and juxtapose these trends through the lens of households.

Doumani, Paula (Washington University) and Robert Spengler III (Washington University) [22]  
**Textiles as an Early Silk Road Commodity: Mobile Pastoralists in Central Asia**

The Iron Age of Central Asia is marked by dynamic and far-reaching interaction spheres mutually operated by mobile and settled societies. The emergence of established trade networks, colloquially referred to as the “Silk Road”, was a stimulus for expanded regional interaction from the Han period (206 B.C.-A.D. 220) onward. Within this setting, textiles of animal and plant fibers comprised a highly valued and multifunctional exchange commodity. While it is believed that Central Asian pastoralists, primarily utilized woolen textiles, poor preservation impedes scientific investigation of regional fiber technologies. In this paper we present exotic plant-based and twill textiles from a pastoralist encampment in southeast Kazakhstan, which include: 1) linen (ca. 400 B.C.); 2) cotton (~ first centuries A.D.); and 3) the first evidence for twill manufacturing technology in northern Central Asia (late 2nd millennium B.C.). The use of twills, in some cases with finely spun threads, and domesticated plant fibers among Late Bronze - Early Iron Age mobile pastoralists of the region suggests a wider repertoire of textiles were utilized than wool, but most significantly, the objects demonstrate socioeconomic connections between small scale pastoral communities and more well-known civilizations of China, South Asia, and Europe.

**Notes on an Interview with Tatiana Proskouriakoff**

As a graduate student, I interviewed and wrote a research paper on the late, great, Tatiana Proskouriakoff (1909-1985). Trained as an architect, much of her professional work was done in the
1930s though 1970s. Proskouriakoff began her career at the University of Pennsylvania Museum with Linton Satterthwaite and worked at Piedras Negras in Guatemala (ca. 1936-1937). Later, she formed part of the Carnegie Institute of Washington's field team to Copán, Honduras (starting in the late 1930s), working with Sylvanus G. Morley and others. For many years, she was affiliated with Harvard University in Cambridge, Massachusetts (ca. 1958-1985). Among her principal contributions to the field of Maya archaeology was establishing unequivocally that Maya hieroglyphic texts communicated history; documenting the reigns of rulers. Additionally, her reconstructions of Maya architecture and recordings of relief sculpture set scientific illustration standards in Mesoamerica. Tatiana Proskouriakoff won a number of prestigious awards, including the Alfred V. Kidder award in 1962, the Pennsylvania State Woman of the Year award in 1971, and Guatemala's Order of the Quetzal in 1984.

[219] Correcting Old Cultural Sequences: Revisiting the Development of the Virú State on the North Coast of Peru

Early states have been a hotbed of research in the Andean region in recent years, with much attention going towards incipient and secondary states on the coast and highlands. On the north coast of Peru, archaeologists studying early states rely on valley-based cultural sequences that originated with the seminal work of Gordon R. Willey and James Ford in the 1940s. Working in the Virú Valley, Ford, Willey, and their colleagues were the first to develop a long-term cultural sequence for any north coast valley. Their work is largely preliminary and untested, and yet it has formed the basis for subsequent studies in other valleys while Virú itself has been largely overlooked. In this study, I revisit the cultural sequence developed by Ford and Willey, re-seriate the sites included in their work, and study the development of the Virú (Gallinazo) polity out of Puerto Morin (Salinar) society (ca. 150 B.C) using modern spatial analytical tools (GIS). While Willey’s hypothesis that the region’s earliest state developed during the Virú Period is still supported, I argue that archaeologists need to revisit the basic dating of cultural sequences for north coast valleys because these sequences still rely on many untested assumptions.

[321] Earlier than Expected: Specialized Pottery Production in the Southwestern United States

Specialized production of pottery for exchange was an important component of socio-economic patterns in prehistory in the Southwestern United States. Specialized production has been documented among low-energy as well as more complex societies in diverse settings. An important question is when specialized production became important in the region. A look around the Southwest suggests that specialized production was well established in the Sonoran Desert of southern Arizona by A.D. 600-700. At the Mustang site in the lower Verde River Valley, located 90 km east of the Phoenix Basin, 70 percent of the pottery associated with the Early Formative component was not locally produced, and multiple production sources were represented. Social mechanisms are suggested to account for this distribution. The early development of specialized pottery production, and likely other materials for exchange and/or markets, established some initial conditions for subsequent cultural elaboration.

Doyle, James (Dumbarton Oaks)

[61] New Light on the Late Middle Preclassic (600-300 B.C.): Lessons Learned Since the Curl Lecture, 1985

"What happened in the late Middle Preclassic, and why, is one of the most crucial research topics in Maya archaeology today; here lies the key to the genesis of Maya civilization." Norman Hammond’s observation almost 30 years ago still rings true. Many recent discoveries at sites such as Ceibal, Cival, and those in the Belize River Valley have clarified the social processes in the early and mid-Middle Preclassic, ca. 1000-600 B.C. Similarly, iconographic and architectural studies of Late Preclassic (ca. 300 B.C.—A.D. 250) materials have rapidly expanded knowledge of the early dynastic Lowland royal courts. This presentation focuses on the murky late Middle Preclassic, ca. 600-300 B.C., in an attempt to shed light on the vital transformations that occurred after the founding of major Lowland ceremonial centers and before clear evidence of the institution of divine kingship.

Doyle, Sean (McMaster University) and Tristan Carter (McMaster University)

[301] Obsidian Source Characterization at Chalcolithic Çadir Höyük
This poster presents the results of an obsidian characterization study of artifacts from Middle to Late Chalcolithic strata at Çadir Hoyuk in Central Turkey. This work forms part of a larger project concerning the long-term history of Anatolian obsidian circulation and use, providing important information concerning the little studied post-Neolithic assemblages. The artifacts were analyzed in the McMaster Archaeological X-Ray Fluorescence Laboratory using EDXRF, the elemental data compared to that acquired using the same technique from geo-referenced geological obsidian samples from sources throughout Central and Eastern Turkey.

The Çadir Hoyuk artifacts can be confidently attributed to at least three sources from the region of Cappadocia in central Anatolia, namely: Gollu Dag, Nenezi Dag and Acigöl. The results will be presented chronologically to discuss subtle changes in procurement during the history of the community, and are compared to data from pertinent sites within the larger region. This research ultimately contributes to our understanding of community interaction and inter-regional trade after the Neolithic, and also to determine the aesthetic and qualitative significance placed on certain obsidian sources at the site both spatially and diachronically.

Drane, Leslie (Indiana University)

The Stylistic and Morphological Study of Ceramic Rims and Vessels from the Cahokian Lunsford-Pulcher Site

The Lunsford-Pulcher site (11-S-40) is a Mississippian mound center located in the American Bottom region, near modern day Dupo, Illinois. The site currently consists of seven mounds and as many as thirteen mounds may have existed at one time. For a ceremonial and village archaeological site, a limited amount of excavation and analysis has been conducted, although Kelly (1993) suggested an occupation period from the late Emergent Mississippian period to the early Mississippian period. A surface collection by Timothy R. Pauketat on discrete portions of the site resulted in a large assemblage, of which 135 ceramic pieces were analyzed for the scope of this study. Based on this analysis, the Lunsford-Pulcher site was likely in occupation from the Late Woodland phases through the Moorehead phase. The largest grouping of ceramics is seen in the Terminal Late Woodland-Lohmann time period, with the second highest assemblage belonging to the Lohmann phase, after which there is a sharp decline, indicating the drop of presence at the Lunsford-Pulcher site. This poster explores the chronology of a Cahokian town through ceramics, contributing to our knowledge about the rise and demise of Cahokia and other surrounding mound centers.

2013 Excavations at the Historic Longest Site and Wichita Fortifications on the Southern Plains

Excavations at a late 18th-19th-century Taovayas village (Longest 34JF1) have provided insights into Wichita fort construction on the southern Plains. Spanish forces attacked this village on the Red River in 1759, and French, English, and American traders visited the Taovayas regularly until around 1811. Visitors described the layout of the village including our first insights on fort construction. Excavations in the 1960s provided archaeological evidence to support historical descriptions, but little information was obtained on the fortifications. May 2013 excavations were undertaken to test various fort features including those mentioned in historic records plus information from magnetic surveys. The excavations documented a moat-like ditch around the fort and "subterranean apartments" that visitors described within the fort. A large post mold may represent part of the stockade. Interior pits and a second ditch were also identified. Daily activities probably occurred outside the fortification as few artifacts were found with interior features.

[168] **Gateway to the Southwest: Archaeology and the American Settlement of the Great Bend**  
The Great Bend of the Red River, in southwest Arkansas, was on the outer reaches of, and a gateway into, the Old Southwest. Like more central parts of the region, the coming-together of Spanish, American, and indigenous communities greatly affected settlement and cultural change in the early 19th century. This paper examines the processes of American colonial expansion into the region and the ways in which settlers brokered competing national and ethnic interests while bringing the area solidly into the Atlantic World economy. By examining many years of research at market towns, river crossings, and small settlements, the links between this area and the Southwest emerge very clearly and show how the negotiation of identity and nation along the boundaries help show, in historical context, the liminal nature of such places.

[114] **Analysis of Site Formation History and Potential Disturbance of Stratigraphic Context in Vertisols at the Debra L. Friedkin Archaeological Site in Central Texas, USA**  
Archaeological sites within physically “active” soils (e.g., Vertisols) are a concern of archaeologists because of potential disturbance of stratigraphic context. Pedology, micromorphology, and geochemistry are tools useful for assessing soil mixing. Clay-rich floodplain soils (Typic Haplustrerts) were examined at the Debra Friedkin site along Buttermilk Creek in Bell County, Texas, USA. The soil contains abundant lithic (mainly chert) artifacts and was assessed for disturbance by vertic soil processes. Vertic features are weak to moderate in the field (slickensides and coarse angular blocky peds), and they are weak in thin section (stress cutans around detrital grains, microslickensides, and cross-striated birefringence fabric). Although there is evidence for clay shrink-swell, there has not been significant upward vertical displacement of older materials and no mixing of cultural horizons. Vertical fractures with dark infilling are narrow, and largely preclude downward movement of even small artifacts. Based on previously published OSL ages and magnetic susceptibility, sedimentation at the site was nearly continuous except for increases during the Younger and Older Dryas, possibly triggered by climate change, and subsequent pedogenesis resulted in uniform element leaching and concentration depth profiles. Vertisols can preserve ‘undisturbed’ Paleoindian archaeological sites and therefore should not be excluded from archaeological surveys and excavations.

[19] **Forams in My Plate: Ceramic Production in Puemape, North Coast of Peru**  
Petrography allows a rare window into the coastal environment of Puemape potters, a Formative ceremonial site of the Cupisnique littoral. Foraminifers, carbonates, ooids, excretion pellets and graminea remains can be observed in the ceramic thin sections of Puemape, along with rounded lithic fragments of mixed composition. All of these inclusions are indicators of a coastal ceramic production. Non-local wares are rare and point to a particular set of wares with graphite decoration produced inland and distributed or traded over to different sites in the Jequetepeque and Cupisnique areas.

[224] **Structure and Termination Deposit of Lubul Huh, Baking Pot, Belize**  
Archaeological investigations of Lubul Huh at the site of Baking Pot, Belize were conducted in 2011, 2012, and 2013 by the Belize Valley Archaeological Reconnaissance Project to develop a chronology and explore the terminal structure of the mound. Terminal structure architecture is composed of two
superstructures made of varying sizes of cut limestone. Approximately 17m of Structure A (horizontally) was exposed although neither corner was found. Structure B intersected Structure A and approximately 5m of Structure B was exposed. Both structures had associated termination deposits with artifacts classes including: ceramics, chert, granite, quartz/quartzite, daub, obsidian, freshwater shell, marine shell, and faunal remains. Diagnostic ceramics included in the deposits date the termination deposits to the Late Classic.

Museum Education and Archaeology: Using Objects and Methodology to Teach 21st-Century Skills in Middle School

Museum educators and graduate students at the Haffenreffer Museum of Anthropology, the Joukowsky Institute for Archaeology and the Ancient World, both of Brown University, and the Rhode Island School of Design Museum of Art are in their fourth year of partnering with sixth grade social studies teachers in Providence Public Schools in a five-session classroom and museum-based archaeology program called “Think Like an Archaeologist.” This experiential program uses the study of archaeological methods to address state and national social studies standards, enabling students to not only understand the science behind the content in their textbooks but also to learn how to use museum objects and archaeological artifacts as primary resources. In addition, the program uses the study of archaeology as a means to bridge social studies content with new nationwide Common Core literacy standards that aim to move towards 21st-century skill building. Students learn to “read” artifacts, to write as historians, and to use academic vocabulary as required by the Common Core while thinking like archaeologists. This program is an effective, successful example of the benefits of archaeological skills in middle school curricula and can be duplicated at other schools in other regions.

Bioarchaeology of the Post-Lapita Manifestation in Fiji: Preliminary Observations and Model Expectations

The Post-Lapita expression in Fiji is marked by significant changes in the dimensions of human behavioral ecology and geographic investigation and incorporation of coastal, inland, and upland environments across the archipelago. These changes are thought to be marked by a decreased reliance on marine foraging and protein-focused diet and an expansion of inland and upland farming and the emergence of a carbohydrate-focused diet. There is some evidence that cultural exchange and/or integration with regional Melanesian populations partially explains the rapidity and magnitude of this subsistence change. Although little is known of the details of Post-Lapita subsistence transitions, our ongoing collaborative research is attempting to discern the archaeological implications of this process, using ecological, spatial and biomolecular datasets. Archaeologically, our biomolecular analyses are concerned with signals of human-environment interaction in and on the skeleton at scales appropriate for discovering diet partitioning, specific taxa consumed and possible cultural affiliation of individual skeletons. These analyses provide well-articulated and justifiable classes of evidence to evaluate competing hypotheses of the mode and tempo of subsistence change in the Fijian Post-Lapita manifestation. We present evidence for a bioarchaeological model of subsistence and biological change and offer a preliminary view of Post-Lapita Fiji.

Transformations in Specialized Ceramic Production at Kirikongo, Burkina Faso (15th-17th Centuries C.E.)

The archaeological site of Kirikongo, Burkina Faso (West Africa) contributes a significant case study of the shift from household to specialized ceramic production. The site was occupied for most of the past two millennia (ca. 100-1700 C.E.), growing from a small homestead to a large village while undergoing dramatic political transformations. While to date research has focused on the development and increasing elaboration of household traditions during the period of increasing inequality (ca. 100-1100 C.E.) and the community-wide changes associated with specialization following an egalitarian revolution (1100-1450 C.E.), this poster explores the previously undescribed transformations in the specialist-produced assemblage during the later phases of occupation (1450-1650 C.E.). For much of Kirikongo’s
history, the local ceramic traditions were characterized by myriad innovations in forming techniques, firing technologies (kilns), vessel form, decoration styles and methods. However, once specialization was well-established in the community (and likely the region), the pottery became simpler for the first time in the site’s history, including the loss of significant decorative diversity. This poster characterizes these transformations in practice and advances explanations contextualized within sociopolitical events in the community.

[123] The Right Tools for the Job: The Manos and Metates of Cerro Maya, Belize

Maize processing is generally presumed to be the primary function of ancient Maya manos and metates; however, analysis of ground stone tools from Cerro Maya, Belize suggests that significant amounts of other products also were prepared with these devices. Use-wear patterns on these stones reflect the items that they were used to process, for example a reciprocal, back-and-forth grinding motion is the most efficient way to process maize. However, non-reciprocal rotary movements are also associated with some types of ground stone implements. This paper will review the frequency and distribution of reciprocal motion flat and trough metates and two-handed manos from Cerro Maya as compared to the rotary-motion basin metates and one-handed manos. Metates of both rotary and reciprocal motion types are present, but basins are predominant and comprise the majority of metates at the site. Manos are highly fragmented and both one and two-handed varieties are present. The implications of these findings suggest that, in addition to maize, significant non-maize food processing also took place, and may reflect the sites function as a center of ceremonial activity and trade.

Duffy, Paul (University of Toronto)

[222] Remote Sensing, Soil Cores, and Systematic Survey in Mortuary Landscape Analysis

The disposal of the dead is a multi-step process often involving a number of people and places over time. Washing and viewing the corpse, burning the body on a pyre (if it is cremated), placing the skeletal remains in containers in the ground, and eating with the bereaved are potentially all important components of the funerary process that commonly leave marks on the archaeological record. Although remote sensing techniques, surface collection, and soil chemistry are increasingly used in characterizing the organization of settlements, they are infrequently used to describe mortuary spaces. This paper addresses the shortfall by using several classes of minimally intrusive data collection to describe activity areas at a Middle Bronze Age (2000-1500 B.C.) cemetery in Eastern Hungary. While prehistoric features and activity areas are difficult to identify using a single line of evidence, we find that the combination of several datasets in a GIS permits both well-targeted excavations and more realistic models of prehistoric activity across mortuary spaces.

[75] Comparative Island Ecodynamics and the “Conservation of Fragility” in the North Atlantic

The ‘conservation of fragility’ is a concept that has major implications for both our interpretation of the past and policies for the future. If fragility is conserved within socio-ecological systems, then any development of robustness to a distinct set of disturbances and drivers of change will necessarily result in increased vulnerabilities to other drivers and other disturbances. We use North Atlantic archaeology and long term human ecodynamics to explore robustness-vulnerability trade-offs and their implications. In Greenland, thirteenth century climate shocks are a plausible trigger for changing Norse subsistence practices. The increased utilization of marine mammals critically-enhanced robustness to one particular set of drivers and disturbances, but vulnerability was conserved and the changing circumstances of the 15th century realized those vulnerabilities, so ending Norse settlement. In Iceland, robustness was
developed to similar but different disturbances and drivers of change. These strategies have succeeded and endured without conserved vulnerabilities becoming realized. Theory would suggest that despite this long-term record of Icelandic robustness, fragility exists that could be realized as a result of contrasting disturbances and different drivers of change. This provides an important caveat to Iceland’s remarkable record of resilience over multi-generational periods and has implications for future policy.

Duke, Guy (University of Toronto)

 Communities in Motion: Peripatetic Households in the Late Moche Jequetepeque Valley, Peru

Households have been variously theorized as social units, physical structures, symbolic representations of interactions, and entanglements of all of the above. This paper examines households as fluid and dynamic social units rooted in multiple locales and pivoting on activities performed by household actors. I highlight the agency of both people as household members as well as the material elements that serve to both unite and differentiate people, places, and things. I focus on the Late Moche Jequetepeque Valley, Peru, where evidence of peripatetic movement of people from location to location for purposes of work parties, ritual observances, agricultural production, etc. blurs the lines between the physical and social spaces these activities occupied. I compare the material manifestations of daily life at two contemporaneous, but discrete sites: Huaca Colorada, a ritual site on the south side of the valley with evidence of both monumental architecture and expedient camps, and; Je-64, a rural site featuring agricultural terraces with living spaces as well as small, permanent, ritual structures. I argue that households in the Late Moche Jequetepeque were dynamic, fluid, and eminently social structures tied to notions of identity and community more so than they were to specific people or places.

Duke, Hilary (IDPAS, Stony Brook University, New York)

 Weaving Simple Solutions to Complex Problems: An Experimental Study of Bipolar Quartz Cobble-Splitting at Eagle’s Nest, NY (3.5-5 kya)

Bipolar lithic technology, the use of a hammer and an anvil to produce tools and process materials, is present across time and space in the Stone Age. This technology is highly variable and serves multiple purposes. However, most studies of bipolar technology describe it as simple, inefficient, and less standardized than other lithic reduction strategies. In this paper we present a pilot study assessing the efficiency and skill of experts and novices employing a bipolar quartz cobble-splitting technique. These results were then compared to those from Eagle’s Nest, a mid-late Holocene (ca. 3.5-5 kya) quartz assemblage on Long Island. Here, bipolar cobble-splitting was embedded with free-hand and pressure flaking techniques to produce quartz tools from split-cobble cores. The occupants of Eagle’s Nest overcame the challenges of time and energy conservation to produce and process these cores. In this case, a skilled interplay of freehand and bipolar techniques minimized the unpredictable nature of quartz knapping. More broadly, bipolar techniques are malleable approaches to navigating contextually dependent tasks. A focus on technological variability in bipolar knapping can help build robust analogies for understanding broader behavioral and evolutionary relationships amongst humans and their ancestors.

Duke, Daron (Far Western Anthropological Research Group)

 What Was Remote or Isolated to Mobile Paleoindians in the Desert West? A Case Study from the Great Salt Lake Desert

Great Basin Paleoindian foragers possessed a specialized adaptation to lake-margin wetland habitats which were unevenly distributed among the region’s large intermontane valleys. Travel between basins had costs that people used mobility to mitigate, but the distances involved also entailed risks related to environmental unpredictabilities. This appears to have become problematic for Paleoindian peoples as pluvial systems declined and desiccated by the Early Holocene. The Great Salt Lake Desert sits in the largest internally drained basin in the western United States. Paleoindian foragers used an extensive wetland area at its center, which would have placed them 30 kilometers from ready exit and farther from alternatives than anywhere else in the region. The archaeology of the area provides a case study for examining how what was previously remote and manageable became increasingly isolated and unmanageable as the environment declined precipitously.

Dulanto, Jalh (Pontificia Universidad Católica del Perú)

 Political and Economic Dynamics of Maritime Communities of the South Coast of Peru During the
Extensively excavated by Frederic Engel in the 1950s and 1960s, Disco Verde and Puerto Nuevo are very well known in the archaeological literature of the south coast of Peru for their occupations dating back to the first millennium B.C. Recent excavations by the Paracas Archaeological Project in these two sites have resulted in the recovery of crucial information to improve our understanding of the role maritime communities played in the expansion and intensification of long-distance exchange networks during this critical period in the history of complex societies in the Central Andes. In this paper, I focus on the compelling evidence we have found of long distance exchange networks of prestige pottery vessels along the Peruvian coast.

Dull, Bryan (Indiana University South Bend) and Joshua Wells (Indiana University South Bend)  
[81] Embodying Materiality within the Landscape: A Multiscalar Analysis of Woodland Earthwork Structures in Northern Indiana

This poster contributes to the discussion of the ways that social and natural landscapes played a role in structuring Woodland lifeways in northern Indiana. The Woodland period is marked by increased complexity, interregional exchange networks, and the construction of earthen monumental structures. Despite extensive research on the Woodland period in northern Indiana, a regional analysis of earthwork placement is conspicuously absent. Earthworks materialize cultural identity by impacting agency and beliefs through ritual practice in relation to natural and social environments. To understand the materiality of the landscape, this research uses a multiscalar analysis of Woodland earthworks and villages. Earthwork data was compiled in collaboration with Dr. Mark Schurr and the Preserve America Mound Project; habitation data came from Indiana DHPA archives. Intraregional neighborhoods were established by combining cluster analysis of habitation and mound center distributions with viewshed analysis, which considered visibility of features across the landscape. Cost surface data was analyzed along with cluster and viewshed data to model how the natural landscape could have affected movement between village and mound neighborhoods. Inter- and intraneighborhood variation was then compared with these datasets to determine factors that could have influenced locational choice.

Dull, Robert  
[158] Reconsidering the Environmental Impacts of the Early 6th-Century Ilopango Eruption throughout Mesoamerica

The largest volcanic eruption to impact the inhabitants of Mesoamerica—and likely the most deadly volcanic eruption ever to affect our planet—was the early 6th century A.D. Tierra Blanca Joven (TBJ) eruption of Ilopango caldera in central El Salvador. Virtually all of El Salvador was uninhabitable immediately following the Ilopango eruption because of pyroclastic flows and deep deposits of sterile volcanic tephra. The total volume of tephra from the eruption is estimated at ~84km3, and it has been geochemically identified as far afield as the Copan Valley, Honduras and the vicinity of Kaminaljuyú, Guatemala. AMS 14C data from successive growth increments of trees growing in El Salvador at the time of the eruption have helped to more precisely date the event, implicating the eruption as the cause of the global atmospheric dust veil and cooling event that affected the earth in the years 536–537 C.E. Assuming that a 535 C.E. eruption of Ilopango was indeed the cause of the well-documented dust veil and cooling, the Classic Period Maya were uniquely situated geographically to experience the full range of impacts of the Ilopango eruption from local biological extirpations to regional drought to persistent global cooling following the event.

Duncan, William (East Tennessee State University)  
[25] What Essences Were Ritually Sealed through Maya Cranial Modification?

Over the past 10 years researchers in Mesoamerica have increasingly come to agree that cranial modification was a normal part of growing up in Maya society. One component of cranial modification appears to have been ritually sealing one or more of these animating essences in infants’ heads. Bodies in Mesoamerica were both permeable and partible and contained multiple animating essences associated with various aspects of personhood, animacy, and illness. Thus, one current question is identifying precisely what was being sealed in cranial modification. In this paper I review animating essences among the Maya to discuss which appear to have been the most likely candidates for sealing through cranial modification. The two most relevant essences are baah and ik’. Baah is a conflation of personhood and the head, could be interacted with by other individuals after corporeal death, and appropriated by enemies. Ik’ is breath soul and could exit the body from various orifices. Although baah is explicitly associated with the head among the Maya, here I argue that ik’ is at least as likely as baah to
have been targeted for sealing through cranial modification.

Duncan, Neil (Stanford University)
[250] Multiple Approaches in Paleoethnobotany: Incorporating Proxy Indicators at Buena Vista, Peru
Deborah Pearsall has long advocated through her work the relevance and importance of multiple approaches in paleoethnobotany to archaeological research. Each proxy indicator of the past, plant macroremains, phytoliths, starch grains, and pollen, has unique, relative interpretive value given the context of research. No environment or archaeological site is the same and various factors differentially affect deposition, preservation, and recovery of each indicator type. Using a dataset from the Peruvian site of Buena Vista, a study of plant macroremains, phytoliths, and starch grains provided multiple lines of evidence for diet, economic importance of non-local introduced cultigens, and the use of foods in a ritual context, whereas each indicator type alone would have had only minor interpretive value at the site. This example, among many others, supports the continued need for better methods and techniques in compiling, comparing, and interpreting data sets that incorporate multiple proxy indicators.

Duncan, James and Carol Diaz-Granados, Ph.D. (Washington University, St. Louis, MO)
[251] The Mace and the Bi-lobed Arrow: Their Place in the Cosmos
Two of the most defining symbols associated with the Mississippian Ideological Interaction Sphere are the mace and the bi-lobed arrow. These two motifs, and their earliest dated imagery, have been found near the confluence of the Missouri and Mississippi rivers. This region had long been the cradle of ideology, and hence its associated iconography, for much of the Mississippian world. Previous scholars have used these symbols to establish chronological parameters without attempting to connect the motifs themselves to any spiritual or cosmological use within societies that employed them. We believe that by studying the co-occurrence of mace and bi-lobed arrow motifs, particularly in the region’s rock art, we can construct at least two possible rites in which these icons were used to identify important celestial characters.

Duncan, Marjorie
[280] Calf Creek Campsites on the Flint Hills of Kansas and Oklahoma: The Grouse Creek and Kubik Sites
Groups of hunter-gatherers known today by archaeologists as Calf Creek foragers lived on the southern Plains about 5500 years ago. This paper discusses two Calf Creek sites on the western edge of the Flint Hills; the Grouse Creek site in south-central Kansas and the Kubik site in north-central Oklahoma. Grouse Creek is a surface find with over 300 Calf Creek-style points indicating variation in the amount of heat treatment and reduction strategies but without subsistence remains. In contrast, the deeply buried Kubik site has few tools but is the best-dated Calf Creek campsite in Oklahoma. The few lithics and faunal remains at Kubik provide additional context to the unique surface collection from Grouse Creek.

Duncan, Lindsay (University College London)
[341] Waste and the Environment: Long-Term Environmental Signatures at a Coastal Maya Site, Marco Gonzalez
The Maya site of Marco Gonzalez on Ambergris Caye has a long occupation history from ca. 100 B.C. until at least A.D. 1300s, including intensive processing activities, thought to be salt production ca. AD 600-800. As suggested by the site's distinctive soils and vegetation, the site's occupation, as seen through cultural materials deposited and resources used, appears to have played some part in the trajectory of local ecosystem development. The current project aims to investigate the development of distinctive soils, notably black earths, which can be used to look at questions of long-term settlement sustainability and impact, through resource use and waste disposal, which might have applications for modern waste and materials issues. The 2013 summer field season, including coring, soil micromorphology and archaeobotanical sampling, was aimed at uncovering soil profiles which spanned the site's occupation, to understand the morphing of the environment through to the present, with cultural contributions forming one facet of a complex ecological history. This paper will present the initial results of the 2013 investigations, including thoughts on resource use by coastal Maya, and the impact of waste disposal on the long-term formation of ecosystems.

Dungan, Katherine (University of Arizona) and Matthew Peeples (Archaeology Southwest)
[333] Geography, Geometry, and Religious Transformation: Great Kivas and Social Change along the
Southern Colorado Plateau and Mogollon Highlands

Large public and religious structures in the 11th to 14th century Mogollon Highlands and on the southern Colorado Plateau share the label “great kiva” and have often been interpreted as having an integrative function. There are, however, substantial differences in the form of structures between the two areas, the most obvious being that Mogollon great kivas are typically rectangular while those farther north are circular. Furthermore, the relationship of such structures to settlements across the greater region – and likely the roles they played – changed through time as they were incorporated into larger settlements and into more complex systems of religious space. This raises questions of how, when, and if great kivas served to integrate communities. We begin to address such questions by comparing the two great kiva traditions through time, exploring the size and structure of the communities that surrounded great kivas, their articulation with other forms of religious or public architecture, and comparative evidence for ways in which these structures were constructed, used, and retired. Areas in which these two traditions intersect (in particular the Upper Little Colorado) are particularly germane to this discussion, with questions of integration and disintegration taking on new importance in such borderlands.

Dunham, Sean (Michigan State University & CCRG, Inc.)

An Analysis of Late Woodland Archaeological Site Locations in the Eastern Upper Peninsula of Michigan

The relationship between people and their physical environment is a critical facet of the study of human culture in the past as well as the present. This paper revisits Late Woodland (A.D. 700 to 1600) settlement and subsistence models for the Upper Peninsula of Michigan. The dominant model for this region, the inland shore fishery model, derives from a relatively small number of coastal Great Lakes sites. Recent research examines data from both coastal and interior sites resulting in a more complete picture of Late Woodland settlement dynamics. The results show that Late Woodland peoples exploited certain site settings and habitats more extensively than others. Some site settings appear to change over time, and others exhibit characteristics of culturally modified landscapes. While it can be assumed that the distribution of Late Woodland sites reflects the location of resources used by Late Woodland peoples, their distribution is not entirely random and suggests that other cultural factors played a role in the selection of site locations. This exploration of ecological and cultural factors influencing choices of site location at different times and in different areas of Michigan's Upper Peninsula is well situated within the framework of settlement ecology.

Puuc Region Paradox? Water and Settlement in the Hill Country of Yucatan

The Puuc, or hill country, has long been known to contain some of the most productive agricultural land in the Northern Maya Lowlands, yet is perhaps the most water-challenged part of the region. The Puuc has been thought to have experienced a settlement history quite different than many other areas, including scant early occupation, and an anomalous fluorescence in the Terminal Classic. However, recent research indicates a much longer time-depth for settlement in the Puuc, including the presence of sizeable Middle and Late Preclassic centers made possible by investment in large reservoirs. In contrast, during the Classic, widespread occupation of the Puuc occurred, made possible by the construction of thousands of household cisterns. Analysis of speleothems from inside and outside the Puuc indicates that the region experienced fluctuations in rainfall similar to those throughout the Maya Lowlands. The hydraulic adaptations needed to survive in the Puuc likely helped Maya communities in the region withstand some droughts that brought down settlements in surrounding areas. Nevertheless, Puuc communities were inherently vulnerable to prolonged or extreme aridity and droughts ultimately were a significant factor in cultural and demographic disruptions within the region.

Small Vertebrate Zooarchaeology of Muge: Preliminary Results on Subsistence, Seasonality and Social Complexity

The aim of this paper is to reconstruct economic aspects related to diet, subsistence, and settlement patterns, through the study of the remains of small vertebrates, marine and terrestrial, from recent excavations of a Mesolithic shellmidden, Cabeco da Amoreira, in Muge, Portugal. A secondary objective is
to infer socio-economic transformations, from which the more recent data seem to indicate clear
distinctions on the basis of intra- and inter-site patterns, reflecting social status, stylistic and ethnic
differences. The approach will offer an ecological and economic perspective in a way that makes possible
to address questions about these people's subsistence, based on settlement dynamics and its relation to
seasonality, type of resources, the observation of capture systems (dependent on species?), and non-
dietary catch.

[247] Life and Health in the Point Community, an Ancestral Puebloan Population in the Middle San
Juan Region, New Mexico

A bioarchaeological project was conducted at two sites, the Tommy and the Mine Canyon sites, in the
Point Community, a Chacoan outlier community in the Middle San Juan region. These sites are located
on the B-Square Ranch just to the south of Farmington, New Mexico. Our research included analyses of
demography, paleopathology, bone chemistry, discrete dental traits, craniometrics, and mitochondrial
DNA. This project revealed changes in demographics and health patterns over time from the late Pueblo
I through Pueblo III periods. These changes included fluctuations in male to female ratios, as well as
shifting workloads, particularly for the Pueblo III period female population. Differences in the
mitochondrial DNA also were discovered, revealing the presence of a distinct subgroup in the later, Mine
Canyon population. Results of these studies reveal increasing variability among site samples across the
Middle San Juan region in the transitional Pueblo III period.

[45] What's Rocks Got to Do with It: Results of a 10,000-Acre Survey at Fort Irwin and the
National Training Center

This poster presents the results of a 10,000-acre survey conducted by Statistical Research, Inc., (SRI) at
Fort Irwin and the National Training Center, in the central Mojave Desert in California. The 10,000 acres
were divided into three large survey blocks, each between 3,000 and 4,000 acres. SRI recorded 113
prehistoric sites and 1,108 isolates, totaling over 46,000 artifacts. Although each survey block had unique
geo-morphological and topographic characteristics, prehistoric sites discovered in each of these survey
areas were typically related to lithic procurement and surface quarrying. We investigate regional scale
settlement and land-use patterns tied to the surface quarry sites recorded during this survey.

Dutillieux, Fanny
Chamba, Center of the Himalayas? Human Appropriation of a Mountainous Landscape

Following a pattern widely recognized in the Indian sub-continent, people of the Himalayas tend to appropriate the landscape in which they live. By naming "Kailash" the highest mountain in their valley, they make it a holy center, equivalent to the famous Kailash. The dynasty of Chamba, in Himachal Pradesh, left archaeological traces that indicate that the rulers tried to build consent-to-rule by turning the geomorphological features of their mountainous territory into holy places, thus transforming the small valley of Chamba into a macrocosm. For the villagers of Chamba, the valley is inhabited by ancestors, naga (snakes), ghosts, and village deities. A particular corpus of sculptures appears in Chamba as early as the 10th century. The fountain stone slabs of Chamba are decorated with representations of pan-Indian deities, naga, ancestors and deceased warriors. Thus, we find in the small valley of Chamba an organized cult, receiving royal patronage. As a similar process of appropriation is expressed by common people with the fountain stone slabs, we attempt in this presentation to compare those two levels of religion. They both indicate that the valley is a center with a strong cultural distinctiveness, linked to the mountainous landscape.

Duwe, Samuel (Eastern New Mexico University)

Summer and Winter People: The Development of Tewa Pueblo Moieties

The Tewa of northern New Mexico are unique among the Pueblos for their emphasis on dualities. Nearly every aspect of Tewa life is structured around the dual-division of the Summer and Winter Peoples. This moiety system, with its inherent tensions and complementarity, has sustained village life for hundreds of years. However, when and how this unique organization was created is up for debate. Using archaeological evidence of site settlement patterns, public architecture (particularly kivas), and ritual landscape data I propose that this unique organization arose in the Classic period (A.D. 1350-1598) through the coalescence of disparate people along the northern Rio Grande and its tributaries. I then discuss why dual-division organization developed as a mechanism to allow for people to aggregate as well as to create a flexible pattern of movement in an environment of ecological uncertainty.

Dwyer, Rachel (SUNY-University At Buffalo)

Blame It on the Rain: Using Statistics to "Weed Out" Plant Materials Incidentally Deposited through "Seed Rain" or Other Additive Natural Transformations

Paleoethnobotanical studies have concentrated their attention to interpreting crop plant materials because these are often recovered in quantities assumed significant and are easily connected to cultural activities. Data from macrofloral analyses documenting observations of plant remains (especially non-crop products) are deemed irrelevant to these research questions and if discussed, they are dismissed as "background noise" or environmental indicators, accidently or incidentally deposited in a cultural context though natural transformations (i.e., "seed rain"). Assumptions of quantities and significance hamper research into other past plant use (e.g., medicinal use, religious offerings, or craft production) that may not leave as obvious traces in the paleoethnobotanical record. Using statistics and data compiled in the SEAD database (Umeå University, Sweden), these assumptions are tested, the effects of incidental and/or natural additive transformations are clarified, and a formulaic tool for determining statistically significant quantities within a recovered sample is discussed.

Dye, David (University of Memphis)

With Culture Heroes on Our Side: Two Realms of Mississippian Warfare

Warfare existed in two articulated worlds for Mississippian people: the realm of interpolity conflict and human experience, and the celestial realm with its culture heroes. Mississippian iconography offers a rare glimpse into these two worlds and how they were intertwined. In this paper I offer an interpretation of how Mississippian elites defined their relationship with violence and warfare in the quotidian world and how they perceived that relationship with other-than-human beings in the celestial realm. Sacred narratives recorded in the nineteenth century provide convincing evidence for the roles that dramatic performance and stories played in chartering warrior behavior. A consistent theme of “trophy-taking” runs through Mississippian iconography, with emphasis on decapitation and dismemberment. Trophy-taking is interpreted here as one way in which life forces were granted by Siouan culture heroes such as He-Who-Wears-Human-Heads-As-Earrings, Morning Star, and Storms-As-He-Walks.

[130] Tallest Mountain, Deepest Lake: Cosmology and Landscape in Maya Centers of the Comitán Valley, Chiapas, Mexico  
This paper explores the ways in which Maya centers in the Comitán Valley of Chiapas, Mexico adhered to and diverged from widespread Maya concepts of sacred landscape. From the cenote at Chinkultic to the caves of Quen Santo, the Maya of this area both shaped and paid homage to the contours of the land on which they lived in the Late Classic and Early Postclassic periods (600-1200 C.E.). This paper considers the ways in which architecture interacted with landscape to express fundamental aspects of Maya cosmology and site-specific identity. I begin with Chinkultic, where a mountaintop acropolis surrounded by lakes and cenotes expressed the city’s control over the surrounding lake region. I continue with Tenam Puente, where rulers constructed a physical and conceptual center by harnessing ideas of mountains and caves. Finally, I examine the caves of Quen Santo, where a previously unexplored sculptural record enables us to understand the site as a center for pilgrimage and ancestor worship. Throughout, I place an emphasis on how these areas would have been used and understood, paying particular attention to ritual and performance as important means of interaction between people, landscape, and worldview.

[128] Late Classic to Late Postclassic Political and Ethnic Boundaries in Western El Salvador: Maya-Pipil Dynamics and Routes of Exchange  
Western El Salvador and regions of Guatemala and Honduras fall into what is often described as the Maya periphery. Late Classic networks of exchange can be reconstructed on the basis of shared material culture, particularly ceramics. Post-Ilopango (circa A.D. 425) resettlement of the Ilopango-devastated zone and subsequent development in central and western El Salvador show that this region was occupied by complex, heterogeneous groups who developed distinctive affiliations with the lowland Maya city of Copan. Routes of exchange appear to have been focused north-south, with less obvious interaction with the eastern Guatemala highlands. By the Early Postclassic, due to forces still not well understood, western El Salvador was largely depopulated, creating a vacuum that the Nahua-speaking Pipil filled during the Late Postclassic. The Pipil redirected interactions towards fundamentally different social, economic, and political ends. While exchange routes in the Late Classic were vectors to reinforce social exchanges, roads during the Late Postclassic were discursive spaces to define Maya-Nahua difference within a new political and economic order.

East, Nicole  
[46] Clay Procurement Strategies and Population Coalescence in the Ancestral Tewa World, New Mexico  
This study explores how human groups alter their use of landscape when experiencing population reorganization. The ancestral Tewa people of northern New Mexico underwent dramatic population coalescence in the Classic period (A.D. 1350–1598) by moving to fewer but much larger villages, while at the same time establishing the boundaries of the Tewa world as recorded in historic documents and ethnographic literature. To understand the relationship between residential reorganization and the development of land use patterns (and in extension the production of social space), I use as a proxy temporal changes in clay procurement strategies for pottery production. I performed X-ray diffraction (XRD) and X-ray fluorescence (XRF) analyses to characterize mineralogical and chemical compositions of temporally sensitive Abiquiu Black-on-gray and Bandelier Black-on-gray painted pottery. These methods complement results from previous chemical and petrographic analyses and allow for a comprehensive assessment of variation within ancestral Tewa pottery in the Classic period. Compositional variation between the two assemblages are then compared to identify shifts in resource procurement patterns of available clay sources and to understand how social and residential reorganization affected ancestral Tewa land use strategies.
Sites in Southern Ontario and Quebec, Canada

Despite their well-established utility in archaeological prospection, geophysical instruments are rarely used in Canadian archaeology. The failure to embrace these techniques may relate to the ephemeral nature of the majority of the region’s archaeological sites, which makes them difficult to detect using geophysics, although it is more likely driven by a lack of familiarity among archaeological practitioners in this region with the techniques and their potential applications. Here we present the results of a number of magnetic surveys on pre-contact sites from southern Ontario and Quebec that demonstrate the great potential of magnetic susceptibility and gradiometer survey in identifying and mapping archaeological features that are commonly found in this region. We also demonstrate that magnetic susceptibility can be used to identify features within the region’s many wood lots (which are notoriously difficult to survey) and to rapidly determine site limits in ploughed fields. Our results show that the cost and time benefits demonstrated for these techniques elsewhere also apply to academic and commercial archaeological research in Northeastern North America.

Excavations at Tzutziy K’in: Preclassic Settlement and Classic Development at an Ancient Maya House Group

Demographic expansion and economic growth during the Preclassic Period (1000 B.C –A.D. 250) in the Belize Valley were accompanied by the appearance of public architecture, sometimes at larger household groups, suggesting increasing centralization of economic power and the emergence of higher status individuals within ancient Maya communities. The goal of excavations at Tzutziy K’in, a large high-status residential group located 2km west of the major political center of Cahal Pech, was to examine the distribution, scale, and technology of ancient Maya household activities from the Preclassic through the Classic periods. Results of radiocarbon dating and ceramic analysis indicate that Tzutziy K’in was first settled in the Middle and Late Preclassic periods (ca. 350-100 cal. B.C.). Major construction in the group began in the Early Classic, with the largest and final construction episodes occurring during the Late and Terminal Classic (ca. 700-880 cal. A.D.). Geochemical sourcing of finished obsidian blades from the site and nearby settlements indicates that the Belize Valley was economically linked to the highlands of Guatemala and that this persisted through time. Changes in artifact assemblages at the group, compared with elite assemblages from Cahal Pech, demonstrate differences that resulted from economic and social inequalities through time.

Moments in Time: Inferring Meaning from Artifact Assemblages at Goat Spring Pueblo, New Mexico

The concept of “moments in time,” one theme of materiality theory, inspires this presentation. Our relationships with Linda Cordell were composed of moments in time, several of which led us to our work at Goat Spring Pueblo, located in the highlands near Magdalena, NM. We believe that this village has three components dating to various phases within the Rio Grande glaze ware period (A.D. 1300-1680). During our recent field work, we encountered multiple artifact assemblages that appear to represent brief moments in time. Considered together, these groups of artifacts provide us with glimpses of specific behaviors. Drawing on materiality and practice theory, we discuss these assemblages and consider possible social practices, meanings, and traditions connected with them. Further, we argue that examining these artifacts as assemblages rather than as separate artifact categories allows us to better understand how these objects influenced, and were influenced by, specific moments in time lived by residents of this village.

[103] Origin of the Offering Skulls and Skull Masks of the Templo Mayor, Tenochtitlan: A Biological and Archaeological Approach

The offerings at the Templo Mayor of Tenochtitlan include decapitated skulls, some of them reused as masks. In this paper we combine the analysis of dental morphological observations with experimental archaeology and SEM analysis of manufacturing techniques to address the questions: who were the offerings at the Templo Mayor; were they local or from outside the Valley of Mexico; and, were the skull masks made locally or before coming to Tenochtitlan? We compared skull offerings from Tenochtitlan corresponding to the reign of Axayacatl (1469-1481 A.D.) with skulls from other groups around the Valley of Mexico, as well as from the Huasteca, Tlaxcala, and the Tarascan Empire. These regions are documented in the Codex Mendoza as military campaigns of Axayacatl. The offerings we examined consisted of skull masks (n = 9), tzompantli skulls (n = 4), and unmodified skulls from sacrificial offerings (n = 34). We used discriminant function analysis to determine whether individuals in the offering samples were similar to the comparison groups. Also, we identified the tools employed in the manufacture of the skull masks. The results presented here are the first attempt to use archaeological and biological data to understand the origin of the Templo Mayor offerings.

[187] Evolution of Arrowhead Complexity in Neolithic Europe

The evolution of lithic arrowhead complexity in Neolithic and Early Bronze Age Europe is reclassified with a new paradigmatic taxonomic system. Archaeological context, sample size and time averaging issues are identified and addressed. We examine the cultural distance between consecutive phases at each site using different diversity indices and then evaluate whether the distribution of these measures exhibit any spatial structure. We further assess correlation with key variables, including population density inferred from C14 data, climate, and subsistence strategies.

[230] Jack Northrop’s Flying Wings at Roach Lake

In 1944 heavy spring rains inundated Southern California, flooding the usually dry playa near Muroc (now Edwards AFB) where Jack Northrop and his self-named aircraft manufacturing company, the Northrop Corporation, had been testing several tailless airframe designs. To prevent delays Northrup searched for an alternate location and turned his attention to southern Nevada, which had escaped the deluge. Northrup and his crew obtained permission to construct a small hangar at Roach Lake, a 2 mile long playa in the empty desert along the highway to Las Vegas. For three months the N-9M-2, XP-56A, and MX-324 flew through southern Nevada skies. Flying wings are theoretically the most aerodynamically efficient designs for fixed wing aircraft. However, available construction material and technological limitations prevented early designs from being successful. The three small wings flown at Roach Dry Lake were a major leap forward, a leap that culminated for Northrop Aviation four decades later in the form of the B-2 Spirit stealth bomber following computer and electronic advances in fly-by-wire systems. Using period photographs the authors relocated the 1944 Northrop hangar site and other locales seen on the lake bed, and replicated the images showing the settings today.

[257] Settlement Connectivity and Power Relationships in Early Bronze Age Northwest Syria: An Integrative Geospatial and Computational Approach

Using least cost pathway and network analyses, this paper employs an integrative approach to provide a more nuanced understanding of settlement connectivity and power relationships in Early Bronze Age
Northwest Syria by considering the impact of topographic and socio-political constraints on movement across the landscape. Particular emphasis is placed on the impact of the rise of a hegemonic state centered at Ebla (Tell Mardikh) on local settlement patterns in the Amuq Plain and Euphrates Valley. It has been suggested that in hegemonic dominance relationships, local settlement systems have frequently been reorganized in an attempt to optimize agricultural productivity in order to meet tributary demands. This paper challenges this notion, arguing that while settlement patterns in the Amuq Plain and Euphrates Valley were influenced by the expanding Eblaite state, this impact was limited, and local trends persisted as the Amuq Plain and Euphrates Valley continued to assert a significant level of political and economic autonomy.

An Examination of Canid Treatment at the Crescent Bay Hunt Club

Dog and other canid remains have been recovered in different types of feature contexts at the Crescent Bay Hunt Club, an Oneota village in southeastern Wisconsin. The majority of the canid remains have been recovered from refuse/storage pits. However, several dogs have been recovered in burial or other specialized contexts, which suggest that at least some canines received differential treatment in life or at least death. The canid remains identified to date from the site will be discussed in terms of osteological markers of post or antemortem treatment.

Archaeology as Long-Term Ethnography: Stable Isotopes as Short-Term Records of Behavioral Variation

In his 1991 paper "Archaeology as Long-Term Ethnography" Michael Jochim considered the effects of year-to-year variation in behavior, and inter-individual differences in decision-making, on the archaeological record of hunter-gatherers. He emphasized that the goal of archaeological research should not be the generation of ethnographies equivalent to those cultural anthropologists write. Instead, the archaeological record has its own, and different, potential for informing on human behavior, the strength being long-term adaptive processes. This paper examines new stable isotope approaches being applied in archaeological research in light of his 1991 paper. The focus, in particular, is the potential of human teeth. Because teeth grow in incremental layers, and the composition of their tissues are affected by a range of dietary and environmental factors, they record life histories of sorts, again with their own potential to inform on human behavior. Such approaches allow us to add considerable detail about the intra- and inter-individual behavioral variation Jochim examined in his paper.

El Temblor Grande. The Ethnohistoric Record as a Means to Understand Past Disasters: A Reassessment of the A.D. 1567/1568 Jalisco Event

In 1567/1568 Jalico, Mexico experienced potentially the one of the worst natural disasters in the history of the region. Called el temblor grande, the ethnohistoric records tells us of an event so large that the ground liquefied and the people faced a fear so great that people thought the world was ending. What makes the 1567/1568 event potentially one of the worst historical earthquake in the history of Mexico, however, is not damages recorded in the historical record but the already disaster state of the region pre-earthquake. Starting centuries before conquest of Nueva Galicia in the 12th century the megadrought and then later with the 14thcentury expansion of the Aztecs un-stabilized the region. The conquest, starting in the 1520s, was particularly brutal. Moreover, the intentional and unintentional consequences of conquest effectively undermined the political authority and social systems of previous autonomous groups resulting in a loss of the traditional effective adaptive strategies developed by native populations to deal with natural disasters. Importantly, these records highlight the potential for the occurrence of a major natural disaster in a region not often considered a high-risk zone for earthquakes.

Remote Sensing in Identifying, Mapping, and Understanding the Use of Karez Water Systems in Maywand District, Southern Afghanistan

In times of conflict, researchers must look for alternative ways to study and protect items of cultural heritage. Remote sensing technologies have proven successful in the identification and analysis of
archaeological remains. Lab work is almost always followed by ground verification, but in southern Afghanistan this is not currently feasible. Remote sensing technologies can assist in mapping karez (traditional water systems), identifying active vs. inactive systems, and determining whether there has been a decline in karez use. This paper presents the results of orthorectified aerial photography analyses for identifying archaeological remains in Maywand District, southern Afghanistan.

Eichner, Katrina (UC Berkeley)
[87] Community Formation in 19th-Century Texas: Preliminary Findings from Fort Davis National Historic Site

This paper presents the initial findings from the 2013 field season at Fort Davis National Historic Site in Texas. Known for its association with African-American soldiers in the 19th century, Fort Davis provides a unique look into race relations on the American frontier. The U.S. Army fort is a promising location from which to archaeologically investigate the effects of race, ethnicity, class, and gender on the formation of a Western American community. A close consideration of the artificial landscape constructed by the military highlights differential areas of living segregated by race, rank, and sex. Through an investigation of households located on fort grounds, the project looks to highlight the economic, political, and personal interactions which took place between different sectors of the community. Military influence on civilian communities through evidence of economic interaction and family building are discussed in depth using the results of geophysical testing, surface survey, and analysis of legacy collections. Future directions for research are also considered.

Eimers, Molly (University of Montana) and Alexandra Williams (University of Montana)

Inhabitants of Housepit 54 at the Bridge River village (south-central British Columbia) participated in a seasonally structured subsistence strategy requiring great knowledge of the regional ecology. Household residents employed careful planning to coordinate hunting and gathering activities with processing and storage to ensure enough provisions were amassed for the winter village occupation when resources were scarce. This system became more complex as Housepit 54 entered the Fur Trade period. For indigenous groups, the Fur Trade offered new opportunities to create alliances and extend power by reworking existing subsistence practices. However, few studies have centered on aboriginal sites or the role of Native culture during the Fur Trade era within the Mid-Fraser Canyon. This faunal analysis informs not only about subsistence practices within a seasonally occupied village, but also about the complex decisions and tradeoffs of Housepit 54 members participating in the Fur Trade.

[319] Merchants, Migrants, Opportunists, and Invaders: The Aftermath of the Fall of the Kaan Hegemonic State in the Gulf Coast Periphery

The mid eighth century A.D. witnessed major transitions across the Maya Lowlands which are clearly reflected in settlement ecology, exchange networks, urbanism, political ideology, and geopolitical dynamics. The breakdown of large political hegemones in the interior Maya Lowlands instigated particularly notable changes in the Western frontier of the Maya Area, as coastal and riverine states transitioned from peripheral participation in political networks dominated by city-states in the Petén to a central role in pan-Mesoamerican exchange networks focused on maritime trade routes. This paper examines the nature and aftermath of the breakdown of the Calakmul hegemonic state in coastal and inland polities in central Campeche. There is compelling evidence that the decline of the Calakmul state opened new opportunities for migrant communities with strong ties to the western Gulf Coast. These shifts resulted in fundamental and long-term changes in human ecology, urbanism, subsistence systems, and networks of political interaction. Epigraphic, linguistic, and archaeological data are combined to evaluate different models to explain these changes, including older Putun and Chontal Maya invasion theories, trade cartel models, merchant diasporas, and pan-Mesoamerican politico-religious movements.

[320] Subsistence Roles in a Late Western Thule Household: A Zooarchaeological Analysis at Cape
Espenberg, Alaska

Faunal remains recovered from a Late Western Thule house (Feature 33, KTZ-088) at Cape Espenberg in northwest Alaska support the idea that paleoenvironmental factors caused a change in subsistence during the Little Ice Age. Archaeofauna from the site provide evidence consistent with earlier Thule subsistence traditions specific to male gender roles, such as hunting large marine mammals. Interestingly, they also demonstrate an increased reliance on shellfish, traditionally harvested by women and children. The results of this analysis provide a look into the subsistence roles performed within a household dating to a period of climate change.

[34] Climate, Ecology, and Social Change in Prehispanic Northwestern Mesoamerica

The northwestern edge of the Mesoamerican culture area fluctuated significantly across space and through time. Cyclical migrations of farming groups from Mesoamerican core areas to the south into and out of this northern “frontier” zone, traditionally occupied by hunter-gatherers, contributed to cultural dynamism within this region. Groups along the northwestern frontier adopted various subsistence and settlement strategies (e.g., hunting and gathering, large-scale sedentary farming systems), the full range of which archaeologists still seek to understand. Although scholars have proposed a number of factors (e.g., climatic, ecological, cultural) to explain these socio-economic contrasts, research in the frontier zone lacks an integrative focus for understanding them in tandem. Coverage of archaeological, ethnohistoric, and paleoecological data is uneven, resulting in significant temporal and spatial gaps in all three records. An interdisciplinary, multiscalar approach to exploring the consequences of interacting cultural and natural factors would greatly improve our understanding of settlement dynamics through time in Mesoamerica’s northwestern frontier. In this paper, I present recent advances in our understanding the settlement history of the region, discuss ongoing challenges, and suggest potential approaches in future research that could lead to a more nuanced understanding of cultural and ecological change in the northwestern frontier zone.

Elliott, Daniel

[196] Six Feet of Earth Makes Us All the Same Size; GPR Prospection of Cemeteries in Georgia’s Coastal Plain

The author summarizes the history and deployment of ground penetrating radar (GPR) for surveys of historic cemeteries in Georgia’s coastal plain. In spite of the difficulty in accessing some privately-funded GPR cemetery information, this data set includes more than 50 studies completed by archaeologists, geophysicists and others since the 1980s. This overview represents the first inventory of GPR deployment in mapping and identifying historic period graves and graveyards in this region of North America. The Georgia coastal plain GPR sample spans a variety of sub-divisions of the coastal plain, including the barrier islands, coastal strand, and interior coastal plain. The investigated cemeteries range from small family plots to large urban cemeteries. It includes cemeteries dating from the early eighteenth-through early twenty-first centuries. The author highlights selected examples of GPR surveys representing different time periods, physiographic subdivisions and sizes. The author evaluates the effectiveness of this remote sensing tool for this physiographic region and he identifies problems, shortcomings and inconsistencies with these data. Overall, the author was impressed with the effectiveness of GPR in an area often characterized by unconsolidated coastal sands, near surface ground water conditions, close proximity to salt water, and heavily vegetated landscapes.

[263] Intrasite Patterning at a Late Pre-Contact Piedmont Village Tradition Settlement in the Upper Yadkin River Valley

The Piedmont Village Tradition (PVT) encompasses many of the Siouan-speaking societies living in the Piedmont region of North Carolina and Virginia after A.D. 200. Within the region, there was significant
variability in cultural practices in different river valleys, which were the focus of settlement activity. At this time we have a limited understanding of PVT community organization in the upper Yadkin River Valley of North Carolina. Only a small number of sites have been excavated, and postmold features and other settlement-related features are not always well preserved, making it difficult to recover data on intrasite activities and patterns. The first season of excavations at site 31YD173 produced results with the potential to inform us about the spatial arrangement of activities within communities. These results are helpful in understanding the variability across PVT societies and communities, the characteristics and development of non-Mississippian societies in the Southeast, and the Mississippian frontier in the Southeast.

The Goodman Point community in the Mesa Verde region contains a high density of archaeological sites. Ancestral Puebloan people lived in small hamlets early on (ca. A.D. 1000) and appear to have aggregated to a large pueblo, Goodman Point (ca. A.D. 1260), at the end of their occupation. Periods of drought occurred prior to the abandonment of this area (ca. A.D. 1300), influencing the availability of animal resources. Zooarchaeological studies have focused on the declining relative abundance of large game animal remains and an increase in abundance of cottontail and turkey remains during the Pueblo II and Pueblo III periods (ca. A.D. 1000–1300). Faunal assemblages from the later occupation periods (ca. A.D. 1150–1300) of the Goodman Point community contain few artiodactyl remains; however, leporid remains, specifically cottontails, are abundant. Zooarchaeological studies of resource depression use the test implication that under substantial harvest pressure, mortality profiles exhibit steepened survivorship (increased representation of juvenile animals). In the Mesa Verde region, remains of large hares (Lepus sp.) decrease in abundance relative to cottontails (Sylvilagus sp.) over time. To assess the potential for intense harvest pressure, we statistically examine temporal changes in leporid survivorship by investigating ordinal measurements of age based upon epiphyseal fusion.

[117]  Dating the Volcano to Sourcing the Ceramics: Geoarchaeology at Desert Archaeology, Inc.

Interest in geoarchaeology has grown over the years not just in the academic environment, but also in cultural resource management. The ability to use techniques from the geological sciences to address a myriad of previously unanswerable questions has led to this increase. Desert Archaeology has a long history of examining sand temper variation to provenance ceramics, but we have also undertaken other geoarchaeology research. This has included the use of x-ray diffraction to source argillite artifacts and scanning electron microscopy to better characterize small beads. Research into the timing of the Sunset Crater Volcano eruption employed dendrochronology, dendrochemistry, strontium isotope analysis, and paleomagnetic assays. Geoarchaeological studies of ceramics have continued to employ petrographic methods to identify provenance and elucidate pottery technology. Ceramic analyses have also included a microprobe study to explore whether non-sand tempered pottery from the Middle Gila River can be
sourced. Petrographic results have also been combined with chemical compositional data from neutron activation analysis in several ceramic studies. These case studies highlight two points: 1) the importance of geoarchaeology in the CRM sector; and 2) the necessity of educating clients in the importance of this research to contribute to a better understanding of past human behavior.

[188] A Smoker's Delight: An Analysis of English Tobacco Pipes from St. George's Caye, Belize

Maya sites have largely been the dominant focus of archaeological projects in Belize throughout the country's excavation history. However, the potential for studying the historic past of Belize is beginning to emerge. Excavations on St. George's Caye, the country's first capital, have revealed a diverse artifact assemblage dating to the country's earliest European inhabitants. English clay pipe fragments, including pipe bowls and stems, represent some of the most prevalent cultural materials discovered within the island's archaeological record. Focusing on several decorated clay pipe bowls and stems, this study aims to analyze the cultural and economic connections between the historic inhabitants and European pipe manufacturers and estimate the temporal ranges of occupation according to dating techniques identified by Seth Mallios.

[115] Reconstructions of Child Labor: A Cross-Cultural Consideration of Children's Labor Activities

If archaeologists want to know what children are doing, it is prudent to study the extant ethnographic record. Previous cross-cultural research suggests that children largely follow adult tasks. However, among some hunting and gathering groups, such as the San, it is reported children largely play and do little work. Whether or not this is a common pattern amongst hunter-gatherers remains to be examined. This paper reports on a comparison of children's work activities with adult activities amongst a sample of hunter-gatherers from eHRAF World Cultures. Hunter-gatherers are also contrasted with a sample of agriculturalists.

Emberling, Geoff (Kelsey Museum)

[329] Ceramics and Trade within Mesopotamia during the Uruk Expansion

This paper presents results of neutron activation analysis of ceramics from Upper and Lower Mesopotamian sites dating to the later 4th millennium B.C. Samples included classic Late Uruk types thought to have been traded (spouted bottles, jars with nose lugs) as well as standard forms that were less likely to have been trade items due to size or poor quality (jars with reserve slip; jars with heavy expanded band rims; and beveled-rim bowls).

In particular, ceramics from Lower Mesopotamia recovered during the surveys of Robert McC. Adams are
compared with similar vessel forms from Upper Mesopotamia: two sites from the Syrian Euphrates Valley (Jebel Aruda and Tell Hadidi); Tell Brak in the Khabur River Basin of northeastern Syria; and Nineveh, located near the Tigris River in northern Iraq. Archaeological contexts for the samples will be discussed along with results of chemical characterization of samples from each site, including the very few outliers that represent likely traded ceramics.

Results of the analysis suggest that groups of clay sources can be distinguished, which had been a source of doubt in Mesopotamian archaeology in the past. Yet the study shows that there was almost no trade in ceramics during the Uruk expansion.

Emerson, Thomas (Illinois State Archaeological Survey) and Dale McElrath (Illinois State Archaeological Survey)

[74] From Squares to Sites: Exposing the Archaeological Record in Illinois

In the 1930s and 40s Fay Cooper-Cole and the University of Chicago played key roles in the introduction of standardized archaeological field techniques and the professionalization of the discipline. But by the early 60s UC had abandoned Midwestern archaeology and institutions such as the University of Illinois, the Illinois State Museum, Southern Illinois University at Carbondale, and the newly created professional organization, the Illinois Archaeological Survey, took a leadership role in creating a new archaeological approach to field investigations – the switch from test squares to excavation blocks, from sampling sites to excavating sites. This change recognized that the primary driver of investigations in the state were development projects tied to road and reservoir construction. Archaeologists as diverse as Lewis Binford, Charles J. Bareis, and Warren Wittry employed heavy equipment to clear large portions of archaeological sites for recovery. This approach caused a sea change in research agendas from those focused on artifact typologies and chronologies to broader issues of community spatial and social organization, inter- and intrasite-level analyses of assemblage homogeneity and variation, and household and landscape archaeology—a focus that continues to dominate the region to this day.

[286] Something’s Fishy: Why Maya Archaeologists Should Use Fine-Gauge Screens (Sometimes)

Decades of zooarchaeological research has shown the utility of fine-gauge screening for recovering representative assemblages from archaeological sites. But many Maya archaeologists continue to use ¼” screens if any at all. Several years of zooarchaeological recovery method testing at Maya sites shows that screening is vital at some sites, but reveals that it is not justified at all sites and within all deposits because of difficulties, cost, and low recovery rates. We suggest a balanced approach to recovery methods for testing, stratified sampling, and careful interpretation that ameliorates the complications of fine gauge screening in the Maya world and elsewhere.

Endfield, Georgina (University of Nottingham)

[17] Re-particularizing Climate: The Importance of Context, Culture, and Complexity

Anxieties over ‘imminent’ climate threats have obscured a long, complex and dynamic cultural history of public engagement with climate and the distinctive meaning that climate and climate change holds, and has held in the past, for different people in different places at a range of scales. Particular experiences of climate changes can become inscribed into the social memory and cultural fabric of communities in the form of oral history, myth, tradition, folklore, technological adaptation or narrative. These different ways of recounting the past represent vital media through which information on long-term climate change and short-lived weather events is gathered and transmitted across generations and can influence how contemporary societies understand risk and prepare for future climate changes. The relational context of climate change, the places people live, their histories, daily lives, cultures or values, is in turn thought to be critical for understanding how different groups of people in different cultural contexts have been affected by and have responded to past climate changes. This paper will argue that understanding these complexities and particularities of past climate-society relationships is thus an important step in helping to understand the way in which contemporary society might articulate and conceptualize future climate

[342]  A Point Refit Study of an Iroquoian Village  
Seventeen summer archaeological field schools on the Eaton site resulted in the recovery of 692 point tips, 129 point mid-sections, and 893 point bases. A total of 114 refits were made between these fragments. This paper examines the distribution of refits relative to longhouses, refuse areas, and the palisade. A number of long distance refits between longhouses were discovered and some possible interpretations of these are discussed.

[178]  Diphrastic Kennings in Formative Period Art: Olmec Iconography, Grammatical Encoding, and the Emergence of Mesoamerican Writing  
This paper explores the existence of diphrastic kennings in Olmec art and writing. Two particularly cogent examples are found on the Cascajal Block, an incised serpentine slab dated to ca. 900 B.C. It is suggested that the iconic signs on the Block are divorced from Formative period representational canons and are instead recontextualized within the grammatical syntax of language. Nonetheless, the signs on the Block and other early examples of Olmec writing are best understood within the wider context of contemporaneous iconography, particularly since many signs found on the Block and other items represent objects regularly depicted in Middle Formative period iconographic systems. It is argued that the diphrastic kennings explored here—one (CS 11 and CS 22) related to rulership and the other (CS 23 and CS 26) to sacrifice—represent one instance of such abstraction from “normative” contexts and therefore offer potentially significant insights into the origin and development of writing in Mesoamerica, as well as onto Formative period Olmec iconography.

[340]  Lithic Raw Material Source Identification at Woodpecker Cave, Iowa  
Identification of technological raw material is an important source of information about prehistoric mobility, landscape usage and social interaction. Lithic raw materials are frequently identified through macroscopic comparison with type collections from known source locations. This was the initial analysis of archaeological material from the late Woodland component of Woodpecker Cave, Iowa. X-ray fluorescence, a potentially more accurate means of identifying the elemental spectrum of raw materials, was performed on the same assemblage. The type collection of the archaeological dominant materials was also subjected to fluorescence analysis. Comparison of results evaluates respective utility of each method and yields inferences about technological behavior of upland rockshelter occupants during the late Woodland period.

Enríquez, Roxana  
En las últimas tres décadas, la arqueología de Colima se ha caracterizado por intervenciones de tipo rescate y salvamento arqueológico debido al acelerado desarrollo de sus ciudades principales. Como resultado existe la exitosa protección y recuperación de vestigios, pero además gran cantidad de información que requiere nuevas propuestas teórico metodológicas para su interpretación. Esta dinámica de investigación es bien conocida en México, pero poco se conoce el esfuerzo que este tipo de intervenciones representa para la interpretación del pasado prehispánico del occidente mesoamericano.

Ensor, Bradley (Eastern Michigan University)  
[118]  Modes, Classes, Gender, and Agency  
Many interpretations of agency are problematic for universalizing and projecting behaviors specific to neoliberal capitalism onto non-capitalist past societies. Meanwhile, Marxist archaeology has been portrayed as ecological or technological reductionism, evolutionary, or unconcerned with gender and
agency. Rejecting that portrayal, this paper illustrates how Marxist analyses can indeed address agency, without faulty projections, among variously contextualized classes and genders interacting within modes or forms of production. Prehispanic Maya, Hohokam, and Taino case studies illustrate how this framework identifies the specific social contexts for different forms of agency leading to cultural changes.

Breath and Smoke: Tobacco among the Maya

Among the most important plant products employed by Native American cultures, tobacco is certainly one of the most prominent. Of the family Solanaceae, sp. Nicotiana tabacum bearing the parasympathomimetic alkaloid nicotine, a stimulant, was selected for a number of properties which ranged from ritual consumption to medicinal purposes. The uses, specifically among the Maya of Central America, are currently being explored. This research reveals that tobacco has been written about, celebrated as a god-like substance, and carried on the person to treat common afflictions for many centuries. From Classical antiquity to the present, it remains a potent ritual substance. This paper explores the ways in which scholars of various fields and specialties assemble the current knowledge of Maya tobacco consumption and employment.

When Space Is Limited: A Spatial Exploration of Chachapoya Mortuary and Ritual Landscape

The Chachapoya culture of northern Peru is often associated with elaborate and visually striking mortuary structures such as anthropomorphic sarcophagi known as purunmachus and burial chullpas, visually situated within the Andean vertical environment. This study focuses on the archaeological site of La Petaca, a natural exposed rock escarpment that was chosen as a sacred space, housing a series of funerary structures located across the cliff. Natural overhangs were selected as open collective burials; however, a large number of small structures were also built into this vertical environment to serve similarly as communal tombs. An analysis of the spatial dimensions reflected in this mortuary expression allows us to explore the ritual creation of this space by the living to commemorate and honor the dead. By using a standardized method of data retrieval and recording, it appears that individuals were deposited over a period of time, resulting in a gradual accumulation and unintentional commingling of the dead. This decision to both construct and continuously return to small sacred spaces within a challenging physical environment may help illustrate the role that cave burials and chullpas play within the greater Chachapoya ritual landscape.

A Comparison of Edge Angle Variability in Experimental “Preferential” Levallois Flakes vs. Debitage Flakes

Using an experimental approach, we empirically compare the edge angle mean and variability exhibited by “preferential/lineal” Levallois flakes (PLF) versus the debitage flakes produced during their manufacture. Using the caliper method of Dibble and Bernard (1980), we recorded edge angle at five flake locations (left lateral, left distal, center distal, right distal, right later) on 75 PLFs and 450 debitage flakes. We conclude with a discussion of edge angle standardization, functional significance, and whether edge angle was potentially a motivating factor in the hominin decision to knap products via Levallois reduction schemas.

Basketmaker Occupation of the Petrified Forest

There is a long history of Basketmaker research on important sites within the Petrified Forest National Park (PEFO). Sites such as the Flattops site and Sivu’Ovi are prime examples of large Basketmaker habitation sites with dozens of structures, which have formed the foundations of our understanding of Basketmaker occupation and landuse. Research began during the summer of 2013 is focused on expanding our understanding of Basketmaker occupation in the Petrified Forest. As part of the PEFO boundary expansion survey project, several large Basketmaker habitation sites were identified. Preliminary recording and research has begun on these sites, and initial findings are presented here.

[299] Archaeological Charcoal Analysis of a Middle Paleolithic Site, Praia Rei Cortico, in Portuguese Estremedura

Charcoal analysis allows archaeologists to identify the woody resources that were available, selected for and utilized by ancient humans over time. This poster presents the results of archaeological charcoal recovered from Praia Rei Cortico, a Middle Paleolithic site dated to 100,000 B.P., The site is located at the edge of a peat deposit that records a five-part pollen sequence of vegetation change during the Last Interglacial. Throughout the pollen sequence, arboreal and shrubby species fluctuate but pine, oak, birch, hazel and Ericaceae are the main woody types. The archaeological charcoal assemblage derives from dispersed pieces recovered from across the site and two distinct clusters likely remnants of hearths. Two species (Pinus sylvestris L. and Myrtus communis L.) have been identified consistently within different areas and levels of Praia Rei Cortico. The results suggest a targeted selection of wood for fuel despite the availability of a broader range of woody shrubs and trees.

[139] Bioarchaeological Investigation as Evidence of Elite Group Status in the Prehistoric Population at Boca del Drago, Panama

This presentation represents a portion of my Master's Thesis research on the skeletal collection from the prehistoric site of Sitio Drago, located off the Caribbean coast of Northern Panama. The research attempts to glean evidence of elite rank social practices by comparing overall skeletal health and the analysis of phytoliths found within dental calculus and from residue on ceramics and lithics found at the mortuary site to collections of skeletal data from this region identified as non-elites. This information will expand our understanding of how prehistoric social rank played a key role in an individual's ability to access nutritionally valuable foodstuffs. This research explores the possibility that Sito Drago is an elite mortuary feasting cemetery where both human and faunal remains, as well as imported ceramic goods, are found. The hypothetical elite remains are needed to comparatively analyze their skeletal qualities with those of contemporaneous remains found in other sites of this region already identified as “non-elites.” Comparative analysis can demonstrate a distinctive osteological difference between levels of social rank among prehistoric societies by showing the effects of preferential food and care accessibility for one group over another.

[190] Pipil Migrations and Postclassic Ritual Landscapes in the Balsam Coast, El Salvador

The nahua-pipil staged a massive diasporic migration from central Mexico to the Central American area. Although it is difficult to establish a specific date of the pipil’s arrival to Central America, there is linguistic, historical and archaeological evidence indicating a strong migration during the Epiclassic (700-900 A.D.) and Postclassic (A.D. 900-1524) periods. During the Conquest period (1524), nahua-pipil groups were located southeast of the Central Pacific coast, south of the highlands of Guatemala, and specifically in the central and western areas in El Salvador. This paper analyzes, from a landscape perspective, recent discoveries of Postclassic archaeological sites registered in the Balsam Coast, interpreting particular geomorphological areas as ritual landscapes, which are formed by both physical and symbolic appropriation. The nahua-pipil treated this region as the ideal place for the development of defensive and symbolic landscape appropriations as part of a process of emulation. This was all designed to preserve cultural identity practices, evoking their deities in order to legitimize their own historical memory through cognitive constructs associated with their homeland.

[72] Ceramic Traditions at the Port of Veracruz, Mexico: Four Centuries of Persistence and Transformation

I investigate local and regional ceramics that are represented at the Port of Veracruz from the seventeenth century to the present day in order to assess the significance of native, African, and Spanish traditions within the port's culture. As late as the mid-twentieth century, locally and regionally produced ceramic vessels were sold for everyday use in the port's markets. Today, potters in central Veracruz continue to produce ceramics, but in the port these vessels are primarily sold in artisan shops as regional folk art. Ethnographic research among these potters is important for understanding changing ceramic technologies and traditions in central Veracruz. I review ethnographic and historical evidence of regional pottery production and exchange. Analysis of the chemical and mineralogical composition and technological style of colonial period pottery recovered from Afromestizo neighborhoods in the port provide evidence of clay sources and procurement methods, formation techniques, and firing technologies. These multiple lines of evidence present an excellent opportunity to trace the persistence and transformation of multi-ethnic traditions through four centuries of post-conquest Mesoamerica.

[316] Home is Where the Hearth Is: Late Holocene Housepit Features from the Black Rock Desert, Nevada

Recent investigations in Nevada’s Black Rock Desert identified three Late Holocene housepit features and associated activity areas from two archaeological sites. While similar housepit features have been identified and investigated from Middle and Late Holocene contexts in northeastern California and southeastern Oregon, few such features are known from this region of the Great Basin. Preliminary analyses indicate these three structures were of similar shape and size, but may have functioned differently based on associated archaeological remains. This poster reports on the preliminary findings of these structures, their ages, and functions in comparison to data generated from housepit features located in nearby regions. These structures and associated remains have important implications regarding the prehistoric use of the Black Rock Desert and can inform on settlement and subsistence practices, raw material procurement, exchange networks, and sexual division of labor during the Late Holocene.

[61]  *Preclassic Maya Civilization. A Perspective from the Holmul Region*

The last decade of research by the Holmul Archaeological project in Northeastern Peten, Guatemala has contributed a high-resolution dataset on the Preclassic period that includes paleo-environmental and settlement data, monumental architecture, ritual activity, and iconography. The interpretation of these data has confirmed many of the patterns of early complexity delineated decades earlier by Norman Hammond with the Cuello, Belize data. The knowledge accumulated here and in other parts of the lowlands now permits a more detailed timeline of the development of civilization in the Maya Lowlands with the identification of important turning points or conjunctures in such development resulting in greater consensus therein among scholars. Patterns of convergence of regional cultural traditions in time and space are also evident in early times and bespeak of processes of increased closeness in cultural and political integration of Maya communities during the Preclassic period. The beginning of these processes can now be traced back to the first emergence of ceramics and sedentary life in the Maya Lowlands around 1000 B.C. Many unanswered questions still remain in that distant and obscure period before 1000 B.C. as to the causes, circumstances, and agents of these beginnings.

[30]  *Lithic Raw Material Choices*

In the Ouachita Mountains of central Arkansas and southeastern Oklahoma, when prehistoric quarries are mentioned, extensive novaculite quarries are the first things that come to mind. In the northwestern part of the mountains, outside the Novaculite Uplift, however, Novaculite-type chert is a minor component of the lithic materials present on most prehistoric sites. A variety of cherts eroded from Johns Valley Shale and silicified sandstone from a variety of sources are the predominant lithic materials available and used. In Yellowstone National Park, Wyoming, obsidian from Obsidian Cliff quarry dominates the area's lithology in much the same way as do novaculite cherts from Spanish diggings in Arkansas. In parts of northwest Wyoming, obsidians from other sources (such as Idaho) or other materials (like chert, quartzite, ignimbrite, porcellanite and steatite) are less common. Farther from Yellowstone, least-cost choices may have caused people to seek more direct and lower-elevation routes to obsidian quarries. The authors compare and contrast raw material choices in these two regions, using source analyses or distinctive combinations of raw materials, in an effort to better understand why people used multiple sources in places where very high-quality materials that were traded long distances were available, or not.

[307]  *Alaska Shipwreck Patterns as Determined by Geographic Information Systems*

Shipwreck patterns of the southern coast of Alaska (16th-20th centuries) are established and analyzed by employing Geographic Information Systems (GIS). Data for this project were provided, with permission, from the State Archaeology Office of Alaska. They consist of geographic coordinates and associated archival data (historical documents and photographs) which I plot and analyze to create a predictive model for future archaeological excavations. From these data I create maps which serve as a case study to demonstrate how GIS technology can be combined with the archaeological and historical record to create a comprehensive visual record of a set of coordinates. My analysis contributes to the history of Alaskan shipwrecks and their spatial significance, and to the history and methodology of GIS. I propose that an increased understanding of GIS applications will improve archaeological excavations, especially at submerged sites. This project provides a method of transforming a cumbersome system of mapping into programs where entire databases can be accessed and manipulated in compact digital files. In turn, my research produces a prototype which can be accessed by other investigators and aims to be a tool that will facilitate excavation and educational outreach in Alaska public archaeology.

[120] Teotihuacan Water Worship and Processional Space

At Teotihuacan, processions were crucial to the social and religious life of the city, as evidenced by murals and also by the plan of the city and the relationship of its built environment to the surrounding vista. A large city in a region where water was the critical resource in least supply, Teotihuacan was always a center of water worship, and as the city’s relation to different water sources changed, so did the veneration of particular deities. Extrapolating from the belief system of the Aztecs, we would interpret the city’s great expanses of avenues and canals as arenas of ritual and processional activity. Looking at probable processional routes within the city, we detect the intent of the planners as they manipulated distant vistas and constructed impressive and meaningful spaces for performance.

[335] 3D Scanning at Small Scales: Implications for Improving Traditional Techniques in Artifact Analysis

Scanning techniques with fields of view below 1m can allow recording of whole artifacts and can provide detail of surface texture for analytical techniques. This paper is framed around improving techniques used to understand social organization and cognition. We briefly discuss the use of nanometer resolution imaging (different flavors of microscopy), and its use for production and functional analysis, and then focus on the application of lower resolution imaging systems for surface capture. Photogrammetry, laser scanning, and structured light scanning are introduced as potential techniques for the imaging of lithics with examples of data gathered by these techniques and the issues related to their use. This is followed by examples of how this data can be used to optimize key traditional techniques within lithic analysis including refitting, morphometrics, and functional analysis. Implications for increasing accuracy and efficiency of techniques are an ability to study larger proportions of excavated samples while at the same time increasing data quality.

[337] Applications of LiDAR at Angkor and Beyond: Towards a Comparative Study of Urbanism in Tropical Forest Environments

LiDAR technology has begun to revolutionize the practice of landscape archaeology in tropical forest environments. Until recently, however, large-scale projects of archaeological LiDAR in those ecological contexts were limited to the Americas, at sites such as Caracol. In 2011 a group of eight research institutions and government bodies formed the Khmer Archaeological LiDAR Consortium (KALC), with a view to reproducing those research outcomes at the great medieval temple complexes of the Khmer. In 2012, KALC successfully acquired 370 km² of LiDAR across northwestern Cambodia, including the World Heritage landscape of Angkor. The results of that mission have transformed our understanding of Angkor as a lived-in space, and have led to new insights into the role of human-environment interactions in the collapse of classical Angkorian civilization. More broadly, ongoing programs of archaeological LiDAR in Southeast Asia, Mesoamerica and elsewhere are now paving the way for a rigorous comparative study of urbanism in tropical forest environments, underpinned by relatively consistent and comprehensive datasets and common theoretical approaches. This paper is a preliminary attempt to chart ostensible parallels and differences in the new archaeological data between different regions, and to explore the potential for moving forward with this broader, comparative research agenda.

[343] Geophysical Exploration of Timber Structures at the Cluny Fortified Village

The Cluny Fortified Village is an enigmatic late Pre-Contact site with characteristics that make it an anomaly on the Canadian Plains. Within the highly visible earthworks, including a 230-m-long semi-circular perimeter ditch and 11 associated pits, excavations have revealed a pattern of vertically-emplaced timber posts. This pattern of posts appears to extend along the inside of the perimeter forming the support elements for an as-yet undefined structure that follows the curve of the ditch. The relatively small size of these posts (10-20 centimeter diameter) makes them challenging to detect by means other than excavation. A geophysical approach to non-intrusively identifying these posts, and thus the extent of
the structure(s), has been explored through a high-resolution ground penetrating radar survey linked with real-time kinematic positioning data at centimeter-level accuracy. The results of this method will be discussed.

Geophysical Surveys at the Fanthorp Inn State Historic Site (41GM79) in Anderson, Grimes County, Texas

The La Bahia Road (also known as the El Camino Real) was one of the main Spanish Roads in the New World, transporting precious minerals, supplies, soldiers, slaves, and religious and political officials throughout their Empire. The exact location of this road, however, is difficult to ascertain as much of it has been either lost to modern development or time. A well known spur of this road, known as the Kinnard Road, runs through Anderson, Texas. In November 2007 the Texas Parks & Wildlife Department purchased land adjacent to the Fanthorp Inn State Historic Site (41GM79) in order to build an addition to the parking lot. In January 2011 ground-penetrating radar and magnetometry surveys were conducted at the site in order to locate the remains of the Kinnard Road. Two linear anomalies were discovered within the data sets, one of cultural origin, the other geological. Subsequent ground-truthing via trenching found the road, proving the effectiveness of the geophysical surveys.

Everhart, Jennifer (Stony Brook University)

Environmental Change? Faunal Exploitation across Climactic Shifts

It is widely recognized that the Early-Middle Epipaleolithic was characterized by a series of climatic fluctuations. However, scholars know far less about how the peoples of the early and middle phases reacted to the resulting changes in their environments. The long-lived Middle Epipaleolithic site of Uyun al-Hammam, Jordan, was situated in an ecotone, with access to at least two major ecological zones. Was this location perhaps selected because it offered resources that would have enabled its inhabitants to maintain a reasonably stable subsistence strategy despite climatic change? This paper will explore the extent to which faunal resource exploitation was influenced by climate change, with implications regarding hunter-gatherer risk-buffering strategies.

Digging the Dirt: An Evaluation of Archaeological Excavation and Recording Techniques and Their Applicability in Forensic Casework

As a result of recent reviews of forensic science that have found many forensic fields wanting, disciplines such as forensic archaeology have been required to ensure that the methodological approaches used by its practitioners satisfy the admissibility regulations of the international courts. These regulations require that any methodological approaches used during the course of a forensic investigation have been subjected to empirical testing, peer review, have known error rates, have standards controlling their operation, and be widely accepted amongst the academic community from which the methodology originates. To date, however, no substantial empirical testing has been conducted, and no internationally accepted forensic archaeological investigatory process has been established. Therefore, as it currently stands, forensic archaeology fails to meet the requirements of the international courts. However, this presentation will discuss the recent research conducted by Evis and colleagues at Bournemouth University that has experimentally compared forensic archaeological excavation methods and recording systems using a controlled grave simulation that will satisfy the court’s requirement for empirical testing. This presentation will also discuss the implications of this research and will examine the potential for the formation of a standardized, tested, widely accepted forensic archaeological investigatory protocol.

Antler and Mammal Bones as Tools: Osseous Technology in Cabeço da Amoreira Shellmidden (Muge, Portugal)

Muge shellmidden, located in central Portugal, have been known for 150 years. Being one of the most important Mesolithic sites in Europe, the archaeological locality is composed by Moita do Sebastiao, Cabeco da Arruda and Cabeco da Amoreira shellmidden. As an important part of the material culture of prehistoric hunter-gatherers, osseous materials are present in Cabeco da Amoreira shellmidden, although bone tool studies are yet to be done. Information has been published about the hundreds of human
burials, but not much about the lithic and faunal assemblages. We present here the results of the technological and typological analysis of the osseous artifacts that were recovered from Cabeco da Amoreira shellmidden in the most recent excavations, from 2008 to 2013, featuring the choices of raw materials, the methods of debitage, and the techniques of manufacturing tools.

Ewen, Charles
[276] The Legacy of the Governor Martin Site
In 1987 construction in Tallahassee, FL revealed a site that later was interpreted as Hernando de Soto’s first winter encampment. Metal and ceramic artifacts distinctive to the sixteenth century entrada were used to identify the site and have since been used to aid in the identification of other Spanish contact sites. These subsequently identified sites have added to the pattern of artifacts that can be used to identify other, contemporary sites. Once identified, these sites, along with the historic narratives of the expeditions, allow archaeologists to reconstruct the political geography of the late prehistoric southern United States as well as better understand the intruders who disrupted those boundaries.

Fabian, Lara (University of Pennsylvania)
[20] Revisiting Roman-Period Eastern Transcaucasia: Entanglements past and present
The Roman-period history of eastern Transcaucasia remains very poorly understood from both archaeological and textual perspectives. The only known kingdom from the region in this period, Caucasian Albania, has been at the center of a highly politicized and heated discourse about ethnic identity and national boundaries in the modern South Caucasus, thus discouraging nuanced archaeological scholarship both in the Soviet period and more recently. However, a growing body of archaeological material combined with more sophisticated models of Roman borderland interactions provide a compelling argument for revisiting the region. In the liminal space between the Roman and Parthian empires, local material culture reflects the overlapping and intersecting identities and agendas of residents, regional authorities and outside actors. Interestingly, this picture of diversity is echoed also in textual references and representations produced by Hellenized and Romanized authors, which, from the early days on, stress the region’s flexible diversity. In stark contrast to modern totalizing conceptions of Caucasian Albania, then, this paper argues that both archaeological and textual evidence for the period in question suggest profound regional complexity and fragmentation and a wide variety of mediatory strategies.

Fadem, Cynthia (Earlham College) and Paul Ermigioitti (Crow Canyon Archaeological Center)
[289] Pedology, the Pueblo Farming Project, and the Village Ecodynamics Project: Intersections and Directions
The Pueblo Farming Project (PFP) seeks to incorporate the knowledge of traditional farming practices and educate the public concerning ancient farming and the unique place of corn cultivation in Pueblo cultures. Project gardens, planted since 2008 in collaboration with Pueblo farmers, provide direct measures of changes in yields across a Mesa Verde Loess-derived catena. PFP results show alignment with predictions of the Village Ecodynamics Project (VEP), albeit with greater variation in yield through time. We recently conducted soil profiling at each of five experimental gardens, including classification of color, texture, horizonation, structure, root density, and carbonate accumulation. We also sampled profiles for future analysis of mineralogy and granulometry, and measurement of ion content, pH, and conductivity. Our examination of dryland (direct precipitation) farming practices and interviews with non-irrigation farmers in experimental, subsistence, and commercial contexts suggests intimate connections between long-term fertility, soil identity, and physical management practices. These findings have implications for interpreting the cultural record of past Puebloan agriculture and modeling paleoproductivity in the VEP.

[87] Evaluating the Effects of Glen Canyon Dam on Downstream Archaeological Sites in Glen and Grand Canyons, Arizona
The role of Glen Canyon Dam operations in affecting the physical condition and rates of erosion at downstream archaeological sites in Glen and Grand Canyons has been a subject of debate for more than
20 years. Although decades of research demonstrate that Glen Canyon Dam has altered the geomorphological and ecological conditions of the Colorado River corridor, the effects of the dam on archaeological sites is still poorly understood. In order to determine if dam-related physical and ecological changes have impacted archaeological site condition, a team of USGS scientists has implemented a multi-pronged research and monitoring project involving high-resolution monitoring of local weather and sediment-supply conditions, repeat measurements of site topography using terrestrial and airborne lidar surveys, mapping of surficial sedimentary deposits, and modeling of potential and actual erosion scenarios. This program is unprecedented in the study of regulated rivers and dam effects on archaeological sites. Preliminary results show that erosion of archaeological sites downstream of Glen Canyon Dam is ongoing, driven largely by overland flow from rainfall events; initial results also indicate that dam operations have affected the ability of the sedimentary system to rebound from erosional events over time, thereby contributing to the degradation of some archaeological sites.

Falvey, Lauren (Desert Research Institute/UNLV)

This paper explores the nature and organization of household activities at the Harris Site through an examination of ground stone technology. Studies of ground stone technology in the Mimbres Valley have often focused on addressing questions related to subsistence practices. The object of this paper is to move beyond a typological documentation of subsistence technology and discuss how tools used in a variety of tasks were manufactured, maintained, and used in household activities. By examining how the inhabitants of Harris organized their daily activities, a clearer picture emerges of how people interacted and negotiated social relationships during the Late Pithouse period.

Fan, Wenquan [126] see Pechenkina, Ekaterina

Farah, Kirby

Xaltocan has been extensively researched over the past three decades by Elizabeth Brumfiel and her students, resulting in an impressive corpus of data pertaining to production, agriculture and everyday life. However, the bulk of this research has focused primarily on commoners and there is a relative lack of information regarding local elites. In an attempt to fill this gap, my research/paper will focus on an elite household near the center of modern day Xaltocan, and will compare with extant data on commoner households to determine how class affected domestic spatial practices. In order to glean ideal comparative data, my paper discusses archaeological methodologies employed similar to those utilized for studying commoner households at Xaltocan. This not only facilitates fine-tuned analyses of day-to-day elite practices but results in datasets analogous to those collected from commoner domestic spaces. Such an approach recognizes that the lives of elites, just like commoners, were shaped primarily by mundane repetitive activities rather than by the more widely studied monumental works. The goal of this research/presentation is to determine the degree to which elite and commoner everyday lives differed, and what these differences or similarities exhibit about class and local identity.

[293] Chair

Farahani, Alan (University of California, Berkeley)

Grand archaeological narratives globally, and especially in the historic Eastern Mediterranean, often rely on monumental architecture and associated elite objects to explain wide-ranging political, social, and economic change. In contrast, the local practices of the communities that constituted these large changes are often overlooked. Intentionally and unintentionally deposited archaeobotanical remains have been particularly under-utilized in exploring long-term changes in everyday practice. Using data from the archaeological site of Dhiban, Jordan, I present the results of several statistical and qualitative analyses of archaeobotanical, artifactual, and other ecofactual remains recovered through four recent seasons of excavation and flotation to explore this topic. Deposit formation processes are sometimes considered
tangential to artifact and feature-centered interpretive frameworks. Nevertheless, long-term changes in depositional practice at the site of Dhiban, especially of agricultural byproducts, wood charcoal, and ceramics, correlate to the interventions of historical non-local polities during the Byzantine (ca. 300–650 C.E.) and Middle Islamic (ca. 1250–1400 C.E.) periods in this area. The holistic integration and analysis of these often independently analyzed categories of archaeological data enhance the reconstructions of the localized repercussions of known periods of tumultuous political change in Levantine history.

Collective Action, Intermediate Sociospatial Units, and Urban Organization in Prehispanic Mesoamerica: An Interregional Cross-Scale Comparison

Anthropological theory on complex societies has begun to incorporate cooperation into explanations of long-term social change. Consequently, the role of commoners in shaping political-economic processes has emerged as a key area of interest. Yet, the impact of cooperation in urban settings has received scant attention, especially in Mesoamerica. This lacuna resulted in part from a lack of information on the internal sociospatial organization of cities, but sufficient data has now accumulated to allow more fine-grained research. Accordingly, using a combination of archaeological, ethnohistoric, epigraphic, and cross-cultural information, we develop an interregional diachronic database (including Classic and Postclassic Central Mexico, Mixteca Alta, Valley of Oaxaca, Tequila Valleys, and Maya Lowlands) to evaluate the degree to which internal urban spatial organization resulted from top-down processes imposed by political architects versus bottom-up processes managed by semi-autonomous households and other groups. These results are then compared with the degree to which cooperation figured into political policies. We hypothesize that highly collective states developed powerful infrastructures that penetrated deep into the social fabric of cities and reorganized intermediate scale units (and households) to achieve collective goals; whereas, states low in collectively lacked such infrastructure and were dominated by a diversity of bottom-up strategies.

San Francisco, the Irish heartland in the West

Over the last decade there have been a number of cultural resource management studies in downtown San Francisco that have encountered mid-to-late-nineteenth-century archaeological assemblages associated with European immigrants to the city. These immigrants included people from Britain, Ireland, France, Germany, Poland, Scandinavia, as well as other countries. However, it has been estimated that first and second generation Irish constituted one in three San Franciscans by 1880 and assemblages related to the Irish in San Francisco form a major component of those that have been recovered archaeologically. This paper will draw on examples from various studies in order to examine the degree to which Irish heritage influenced selected aspects of daily life, such as food and beverage consumption, and purchasing decisions when compared to those of other immigrants to the city during the second half of the nineteenth century in San Francisco.

Long-term Patterns in Garden-Orchard Management: Medicinal Plants and Maya Gardens at Mayapan
This poster will look at the use and management of medicinal plants and trees in a modern Yucatec Mayan garden-orchard and use the results to interpret ethnohistorical and archaeological data related to ancient Maya houselots. The history and origin of these plants will be traced to help understand the long-term evolution of houselot garden-orchards through time. These data will then be compared to similar studies in the Maya area to trace how management strategies may have evolved in the greater context of the Maya area and what strategies may have evolved in response to the local geography of the region. These data were collected in the northwest Yucatan Peninsula at Mayapan, a Late Postclassic Maya site. Mayapan represents a unique opportunity to explore houselot management since much of the urban architecture and enclosed houselot walls are still visible on the surface and have been mapped fully. In addition to the archaeological conditions of the site, due to the late prehispanic occupation of Mayapan, ethnohistoric documents written early in the Spanish conquest reference the site.

Fash, William (Harvard University)

The material culture of Copan, long considered the “eastern-most capital” of the Maya area, reflects a palimpsest of diverse groups and cultural practices from many adjacent areas, beginning long before the Classic period Maya dynasty (426-822 C.E.) and continuing thereafter. Recent research at the outlying residential site of Rastrojon in the eastern end of the Copan Valley uncovered occupational evidence for non-Maya groups both before and after the dynastic era. During the Late Classic period this defensible site became part of a ritual circuit and visual communications system that likely served the ruling dynasty in monitoring activity along the city’s eastern boundary. One of the many elaborately decorated buildings at Rastrojon featured the iconography of war, and the memory of the long-lived 12th king who created the monitoring system. This “palace” structure was dedicated by Ruler 12’s ill-fated successor, who subsequently was captured, possibly on a battlefield. Projectile points found in three buildings at Rastrojon span the Late Classic, Terminal Classic, and Early Postclassic period occupations there. The new evidence suggests that on the eastern frontier of the city, armed conflict was a constant concern in shifting alliances and population movements before, during and after the Maya hegemony.

Fash, Barbara (Harvard University) and ALEXANDRE TOKOVININE (HARVARD UNIVERSITY) [154] Fresh Angles: 3D as a Research and Preservation Tool

How can we study and preserve monuments that are deteriorating at an alarming rate? Using today’s high-resolution 3D scanning technology and printing we stand a chance of reviving some of the world’s sculptural treasures by virtual and physical replication. Not without its challenges, this is our era’s contribution to the preservation of ancient knowledge. The talk will touch on what lies ahead and how 3D applications are aiding in the documentation, preservation, and interpretation of Copan’s lengthy and vulnerable Hieroglyphic Stairway.

Faulseit, Ronald (Tulane University)

[254] Classic to Postclassic Household Economic Strategies in the Oaxaca Valley

The Classic to Postclassic transition, which brackets the decline of the Monte Albán polity, has been the subject of some debate. While a few scholars suggest that the centralized political system experienced a crisis causing rapid demographic shifts, others have argued for a more gradual transition to a system of fragmented and competitive minor states that dominated the Late Postclassic (A.D. 1300–1521). Less attention has been paid, however, to what occurred immediately in the aftermath of Monte Albán’s “collapse.” My research focuses on the Late Classic and Early Postclassic settlement at Dainzú-Macuilxochitl, an important secondary center during the Monte Albán era, to examine how the community reorganized in the post-Monte Albán environment. In this paper, I discuss the economic strategies employed in an Early Postclassic house complex derived through the spatial analysis of materials associated with craft production and consumption. These data present a pattern consistent with an economic strategy employing multi-crafting and the procurement of finished obsidian tools, which suggest dependence on regional market interactions.

[112] Is It an Absence of Evidence or Is There Evidence of Absence in Dynamic Interactions in Tlaxcala and Puebla?

If we view Tlaxcala and Puebla as regional places of unique material character, our method for understanding dynamic interaction is based on material comparisons between local and more regional centers of influence. If we see material evidence we might conclude there was dynamic interaction. If there is no material evidence should we conclude there was no interaction? If on the other hand we view Puebla and Tlaxcala as areas with inhabitants who made behavioral choices based on relational and environmental constraints and opportunities we may understand interaction over time in other terms. Such a paradigm that frees our thinking about Tlaxcala and Puebla as essentially unique allows us to study patterns that occur in other places and times to follow the particular trajectory of interaction in this area of Mexico over time.

Faust, Katherine (UC Riverside)

The Iconography of Huastec Engraved Shell Ornaments and Ceramics

The pre-Columbian peoples of the Huastecas produced one of the most unique corpuses of ancient Mesoamerican iconography, inspiring the interest of scholars since the turn of the nineteenth century. The main focus of this study are the materials known as Huastec Black-on-White and Tancol Polychrome ceramics, as well as engraved conch shell ornaments. Motif permutations adorning these objects are highly standardized, underscoring the significance of context and location in the production of meaning. I will explore the multiple meanings embedded in Huastec iconography through a gestalt analysis of motif and form.

Beyond the Periphery: Comparing Complexities in Coastal California

All societies are characterized by some degree of resistance to hierarchical authority. This is equally true for societies whose members toil under an entrenched state apparatus as it is for those where the state exists primarily as a mythological concept opposed to individual autonomy. Pre-Hispanic California was geographically distant from the experience of the Mesoamerican state, yet individual Californians would have obtained knowledge of such authoritarian ways of living through regular and well-documented exchange with the American Southwest and Northern Mexico. This paper explores the impact that such concepts of authority might have had on the development of societies of resistance in coastal California. We explore the material and ethnohistoric evidence for a long history of connections between coastal California and inland areas and compare how different Californian societies chose to navigate their experience with organizational authority. We argue that coastal Californian hunter-gatherers were aware of the ways of living experienced by their eastern agricultural neighbors, and suggest that the social and political trajectories of the region cannot be understood outside of broader known landscape.

Faux, Jennifer (SUNY Buffalo)

Fingerprinting the Past: A Dermatoglyphic Evaluation of Figurine and Candelero Production at Teotihuacan, Mexico

Household craft production has been a research concern of archaeologists for decades with the aim of reconstructing the sociopolitical economy of past societies. Given the difficulty of determining how and where goods were produced, and particularly who produced goods, archaeologists have surmised that the identification of craft producers may be indeterminable. In this paper, the social implications of figurine and candelero production at Teotihuacan, Mexico, will be evaluated by determining the sex the figurine and candelero producers. Household-based production at Teotihuacan will be studied through the examination of material culture recovered from the 1959 excavations of Plaza One, currently housed at the University at Buffalo. In an attempt to deconstruct the social implications of figurine and candelero craft production at the residential level, this paper describes an effort to determine if figurine and candelero production was gendered. Through the use of paleodermatoglyphics, or fingerprint analysis of archaeological material culture, and ethnographic analogy, the present research aims are to assess the sex of past figurine and candelero producers in an attempt to understand the boundaries of household-based craft production at Teotihuacan and reveal divisions of labor at the residential level.

[177] Excavating Underwater Maya: Does the Shell Midden Enhance Preservation in the Mangrove Peat?

Mangrove peat provides an ideal matrix for the dramatic preservation of wooden architecture below the seafloor at ancient Maya salt works in Paynes Creek National Park, Belize. The absence of animal bones and human burials typical of ancient Maya communities is not surprising due to the slightly acidic peat, and perhaps not expected at the salt works. Several of the Paynes Creek salt works have associated shell middens, where animal bone or human remains could be preserved due the addition of a calcium carbonate compound to the peat matrix. Excavations in Spring 2013 were carried out at a shell midden associated with a wooden building at the Eleanor Betty underwater salt work to discover whether bone was present. In this paper, we describe mapping and underwater excavations at the shallow inundated Eleanor Betty salt work, including the shell midden and the accompanying wooden architecture.

[330] Maya Cornucopia: Indigenous Food Plants of the Maya Lowlands as Commodities

Agricultural products are generally considered the most common of commodities; marketable items produced to satisfy wants or needs. Corn, or maize, is the soft commodity usually thought of as the food product of ancient Mesoamerica that could be marketed and potentially transported over significant distances. Other food commodities such as cacao were certainly important and marketable, but could be thought of as satisfying elite wants rather than common needs. This presentation will consider the 500 indigenous food plants of the Maya Lowlands, and explore the potential commodity value and transportability of food plants that might have been carried in the Maya cornucopia.

[18] Managing Digital Data in the Laboratory for NGWSP

The Navajo-Gallup Water Supply Project provides a case study for incorporating cutting-edge capabilities in archaeological data management, as well as the hurdles to implementing these methods. There has been a proliferation of digital data in archaeology over the past several decades. Often, massive datasets have been generated with little attention paid to the tools required to leverage and curate such datasets. Developments in smartphone and tablet hardware over the past six years have brought digital data collection workflows to the fore in archaeological field studies, making the effective management of digital datasets all the more critical. This paper outlines advances made by PaleoWest archaeology in managing data collected in the field and laboratory, and in the context of managing collections, conducting analyses, reporting, and curation.

[155] In the Valley of Waters: Archaeological Investigations at a 19th century African American
Cemetery (41NV716) in Navarro County, Texas.
The postbellum period in Texas was a time of rapid transition and intense social upheaval for blacks and whites. Black communities in particular withered and reformed, as people migrated to other places in search of family, new employment, and land to call home. This paper looks at the aftermath of the Civil War through mortuary remains from the Montgomery Hill Cemetery in Navarro County. This unmarked cemetery, located within the Richland-Chambers Reservoir, came to light during the drought of 2009 when falling lake levels exposed human remains on a beach. Subsequent excavations, oral histories, and research suggest that African Americans from around the town of Eureka were interred here just after the Civil War. The material remains from the cemetery suggest a hybridized spirituality coupled with a deep sense of tradition among community members. But research has also exposed the precariousness of existence for African Americans after emancipation. This paper highlights how artifacts found with the interred remains reflect the endurance of a specific African American spirituality and community identity within a context of social change.

[148] Returning to Last Supper Cave: New Results from AMS Dating and Ongoing Analyses of a Late Paleoindian Occupation in Northwest Nevada
Located in the High Rock Country of northwest Nevada, Last Supper Cave was tested in 1968 and fully excavated in 1973-1974 under the direction of Tom Layton and Jonathan Davis. The site revealed a long sequence of human occupation including an extensive Paleoindian component initially dated to ~9,000 14C B.P., although large standard errors on many radiocarbon dates precluded precise dating of the early occupation. In 2008, a hearth from the lowest deposits returned an AMS date of 10,280 14C B.P., suggesting that the initial occupation occurred during the latest Pleistocene, over a millennium earlier than initially believed. Here I present results of further AMS dating of the early deposits at Last Supper Cave as well as my ongoing analyses of diagnostic artifacts to determine the stratigraphic integrity of the site. I also point the direction towards future research with the Last Supper Cave materials, which will make use of an old collection to reveal additional information about early prehistoric lifeways without furthering our impact on the archaeological record.

[58] Botswana, Southern Africa and Glass Bead Trade in the Indian Ocean during the 1st and 2nd Millennium A.D.
Imported glass beads are important evidence to study Indian Ocean trade. The presence of thousands of imported glass beads on archaeological sites in eastern and southern Africa are an excellent example of this, but questions remain about the potential sources for these beads. Typologically, these beads are similar to beads from Southeast and South Asia and the Middle East. Glass beads from Botswana, and several other locations in southern and eastern Africa were subjected to chemical composition analysis and grouped into various glass “recipes”. Many of these can be correlated with known broad regional glass manufacturing traditions. In this paper I will present and discuss the compositional data as well as lead, strontium and neodymium isotope analyses of a sub-sample of glass beads from these sites and regions. These beads originate from contexts dated from as early as the 8th century A.D. until the 17th century A.D., and include several defined chronologically progressive typologies. Possible provenances for the raw primary glass production and bead production are suggested from the elemental and isotopic data. These isotopic results, combined with the chemical compositions, have identified at least two primary regions of origin for the glass beads, the Middle East and South Asia.

[94] Tradition and Modernity on Great Blasket Island, Ireland
This project in archaeology, history, and landscape studies examines the lifeways of residents of the
Great Blasket Island off the southwest coast of the Republic of Ireland in the period of 1800 through the early 1900s. The lifeways of the residents on the Great Blasket Island were the focus of concerted, nationalist mythology construction by proponents of the new Republic of Ireland in the early 1900s. Those lifeways, supported by maritime and agrarian subsistence, were hailed by nationalist advocates as representing an authentic Irish cultural identity uncorrupted by the impacts of British colonialism, modernity, or new consumer markets. Great Blasket’s population decreased as emigration to America or to the mainland towns of the new Republic of Ireland drew families away. All residents had departed that island by the 1950s and no research has examined the cultural landscape and archaeological record of their actual lifeways. This project examines what was known about the lifeways of the islanders from ethnographic and historical descriptions, and the likely ways in which those accounts were shaped by nationalist sentiments in the early 1900s. Those accounts can be compared and contrasted with data from archaeological investigations and cultural landscape studies.

**[41] Fit for a Khan: Stable Isotope Analysis of Elite Mongolians from the Mongol Empire Period**

During the thirteenth century A.D., Mongol peoples from the steppes of Central Asia conquered a huge swath of Asia and eastern Europe. Diet is one cultural component that might have changed as Mongol people became both wealthier and more knowledgeable of foreign customs. Here, we use collagen carbon and nitrogen stable isotope analysis of human remains from eastern Mongolia to see whether certain aspects of diet differed between a group of probable Chingisid elites buried in a cemetery at Tavan Tolgoi in southeast Mongolia and a group likely composed of lesser elites or commoners. We also compare the Chingisid data to data from Mongolian pastoralists from the Bronze Age and from the immediate post-Empire period. The results indicate that the elites had significantly different stable isotope ratios, but it may be related to environmental rather than dietary differences.

**[336] Restos de textiles en un contexto de ritual de abandono. El caso de El Rosario, Querétaro**

Durante los trabajos de exploración del principal edificio arqueológico de El Rosario - lugar considerado como enclave teotihuacano en el Valle de San Juan del Río- fueron localizadas una serie de objetos como pequeños cuchillos de obsidiana, puntas de proyectil y una importante cantidad de fragmentos de braseros, todos ellos cubiertos por una gruesa capa de ceniza y troncos carbonizados. En ese mismo contexto, se localizaron algunos restos de textiles. En este trabajo se plantea que dicho contexto corresponde a un ritual de abandono del sitio hacia 650 d.C. coincidiendo con la “caída” de Teotihuacan, además de que la evidencia se encuentra depositada sobre el piso correspondiente a la tercera etapa constructiva del edificio y última asociada a la ocupación teotihuacana en este lugar. Consideramos que la localización de los fragmentos de textil dentro de este complejo contexto arqueológico es sumamente interesante e importante de anotar.

Ferguson, Josalyn

While there is consensus that the processes of decline and abandonment at many sites associated with the Terminal Classic Maya “collapse” (A.D. 800-1050) included the movement of peoples across the Maya lowlands, there has been little focused archaeological research on the resettlement and regeneration of these migrant groups. The movement of peoples across the Maya landscape was additionally encouraged by a revolution in exchange systems, with a notable increase in mercantilism and entrepreneurialism across the Maya Area, and a more integrated economic system focused on a wide range of commodities that served to link polities and regions on a more inclusive scale. As a result many regions experienced marked population growths with the expansion of existing settlements, the resettlement of previously abandoned sites, and the establishment of new communities. The Progresso Lagoon region of northern Belize, in the hinterlands of Chetumal Bay is one such area that witnessed such marked population growths. This paper will examine what combination of social, economic and political processes and geographical features encouraged the resettlement and regeneration of communities in this region during this formidable period, as elucidated through the archaeological investigation of the settlement of the Terminal Classic Strath Bogue community.

**[44] From Field to Photoshop: Photo Recording, Post Production Image Digitization and Lithic Analysis of a Rock Ring Feature from 76 Draw, New Mexico**

Throughout the American Southwest and Mexico, prehistoric people cultivated and processed wild agave using a variety of rock-lined pit earthen ovens. 76 Draw, a Casas Grandes Medio Period pueblo (1250-1450 AD) located south of Deming, NM, has a rock ring surface feature characteristic of a roasting pit. This anomaly has endured significant site deflation and erosion since its initial recording in 2009. Its evident preservation and possible cultural importance justified more intensive study. During the summer of 2013, the ring was systematically photographed, mapped, and partially excavated. Surprisingly, test excavations yielded few subsurface artifacts and quickly revealed a hard sterile clay stratum. This poster reports the results of the excavation and lithic analysis of the rock feature while also exploring how field photography and postproduction image digitizations facilitate the documentation of large-scale ground features.

Fernandini, Francesca (Stanford University) [245] Cerro de Oro: A Coastal Settlement during the Middle Horizon

This paper will present results from analysis performed on maritime-associated products obtained from our recent research at Cerro de Oro, in the lower Cañete Valley. Cerro de Oro is a large urban-like settlement that experienced important demographic growth during the Middle Horizon Period. This analysis focused on shell species determination, the analysis of contexts with fishing implements, and evidence associated with intensive pluvial events. Through these studies we explore the role marine elements played in daily life as well as understand how the local population dealt with sudden climatic changes possibly caused by ENSO events.

Fernstrom, Katharine (KW Fernstrom & Associates) [215] Topics in the Ethics of Appraising Art-Made-for-Sale and Commodified Antiquities

I am a Professional Archaeologist with extensive Art Museum experience and a member of the SAA, SHA, and RPA. I am starting an appraisal business specializing in Native American and Pacific Islands commodity-art, but I have to establish formal business practices that take a stand against appraising illegally commodified antiquities and ethnographic objects. Collectors of art-made-for-sale frequently possess, buy, and sell antiquities and ethnographic objects. Objects put into commodity circulation before the enactment of the Antiquities Act, the Archaeological Resources Protection Act, and the UNESCO convention of 1970 are not illegal to buy and sell. Further, since these objects have already been removed from their archaeological and cultural contexts, appraising them does not violate the ethical codes of the SAA, SHA and RPA. In and of themselves, however, these statements constitute a sell-out, a cop-out, and an easy-out. It is necessary to demonstrate their commodity-age by such documents as receipts or wills. Further, it is necessary to risk losing clients by refusing to appraise antiquities and ethnographic art that fail the document test. Finally, I wish to proactively educate the public about protecting finite archaeological and ethnographic resources.

Ferraro, Joseph (Baylor University), Katie Binetti (Baylor University), Gary Stinchcomb (Pennsylvania State University) and Fredrick Manthi (National Museums of Kenya) [209] Farre: An Early Middle Pleistocene Archaeological Locality in the Chalbi Basin, Northern Kenya

The Middle Pleistocene of Africa saw the rise of Homo sapiens, the emergence of cumulative culture, and the appearance and proliferation of a battery of sophisticated new technologies. And yet, as relatively few African localities sample this important timeframe (ca. 781 to 126 thousand years ago), the specific details of the timing, setting, and dynamics that underlie the emergence and early evolution of these advances remain poorly understood. With an estimated minimum age of ~600 ka, recent discoveries at the open-air locality of Farre, northern Kenya, add important new data to the early Middle Pleistocene archaeological record in Africa. Initial interest in the site centers on an intriguing assortment of spatially and temporally associated lithic technologies: a combination of tool forms and production techniques that transcend simple assemblage-wide classification to either the Acheulian or to the Middle Stone Age (MSA). Instead, the assemblage reflects a relatively high level of technological skill coupled with tool forms characteristic of both traditions. This result is consistent with suggestions that the transition between the Acheulian and the MSA was a mosaic process; one characterized by non-synchronized advances and retreats in technological know-how, with some general tool forms (points, blades, etc.) likely having multiple independent origins.

[268] _The Development and Application of Nondestructive Portable X-ray Fluorescence Spectrometry for Hohokam Vesicular Basalt Groundstone Provenance Analyses_

Vesicular basalt was often acquired by the Phoenix Basin Hohokam for groundstone tool manufacture. However, the precise nature of this acquisition remains poorly defined due in part to an inability to identify the source of the raw material. This presentation summarizes ongoing research efforts aimed at developing the use of nondestructive portable X-ray fluorescence (PXRF) spectroscopy for vesicular basalt provenance analyses. Evaluations of instrumental sensitivity and reliability, combined with chemical assays of material from nearly two dozen quarry sites, has found that PXRF analyses can provide valid provenance assignments for groundstone artifacts. Moreover, analysis of provenance determinations for a sample of groundstone artifacts from nine Hohokam sites suggests spatial and temporal variation occurred in material acquisition practices. The implications of this patterning for Hohokam groundstone procurement practices and culture history in general are examined.

[242] _Sigatoka Valley Revisited: Preliminary Results from the Post-Lapita Subsistence Transition Project_

Settlement of the interior of Viti Levu, Fiji has long been assumed to have occurred ca. 2500-2000 B.P., during a period that is known as "Post-Lapita," or the early portion of the "Mid Sequence." It has also been assumed that settlement was part of a broad expansion of agricultural production, and the transition of diets with largely marine components to ones with a base of carbohydrates. Our research project, initiated in 2013, seeks to detect the presence of initial settlement in the interior of Viti Levu, Fiji, and examine the linkage of this settlement with major landscape change associated with farming. This presentation reports on the preliminary survey of sites in the Sigatoka Valley and associated GIS modeling. Outcomes and plans for the next stage of research will be discussed.

[116] _Bones Don’t Lie: Approaches to the Social Dimension of the Mortuary Practices at Cabeço da Amoreira (Muge Shellmiddens, Central Portugal)_

The great number of skeletal remains recovered from the Muge sites makes this series one of the most important for the study of Mesolithic societies. Since its discovery in 1863, around 300 skeletons were discovered in the Muge complex. From Cabeço da Amoreira, one of the largest middens of this complex, more than 30 skeletons were recovered but unfortunately any systematic study has been done in previous researches. Given that, little is known about the symbolic value of these funerary practices.
Besides variations regarding grave goods, body position, and chronology, burials can also expose indicators of social status and organization. Based on new analysis and a review of published evidence, including skeleton position and orientation, spatial location and presence/absence of votive materials, the aim of this paper is to discuss the mortuary variations archaeologically visible at Cabeço da Amoreira as a result of a social hierarchy and division.

From Foragers to Early Agriculturalists: The Deep History of the Highlands of Southwestern Honduras

Preceramic research in Honduras has focused on the El Gigante rockshelter, where evidence of early human occupation and a detailed record for a rich foraging economy during the Early Holocene were uncovered. This work also highlighted the potential for hunter-gatherer studies in the area, and presented sound hypotheses to be further tested. This paper presents ongoing research in the Sierra de La Paz mountains, located approximately 15km southwest of El Gigante. Survey and excavation data suggest that this landscape was rich in key resources necessary to sustain foraging human populations, including natural shelters, permanent water sources, and lithic materials. Moreover, research continues to show that the material culture from this area is unique in its level of detail and preservation, and can expand what we know of past lifeways, behaviors, and beliefs, as well as how these developed into the cultural traditions of modern populations.

Photogrammetry and 3D Modeling of Bedrock Features (Mortars and Cupmarks)

Bedrock features such as mortars and cupmarks are known in the southern Levant at least from the late 1920s. Many were dated to the Natufian and the Pre-Pottery Neolithic A periods (15,000-10,300 cal B.P.). The appearance of large and diverse assemblages of bedrock features, reflecting a variety of functions, seems to have played an integral role in the earliest transition from hunting-gathering to food producing economies based on cereals and legumes. Our research team has been studying bedrock features for almost a decade now. Though there are many advances and insights, the accurate documentation and modeling lingered behind. Furthermore, characteristics of production technology, spatial distribution and preservation patterns are yet to be fully established and analyzed. Aspects such as rim morphology, shaft characteristics and size await meticulous intra- and inter-site studies. We present in the current paper new implication of using photogrammetry for a high resolution 3D documentation, even of the deepest and narrowest mortars. We propose geometrical and volumetric analyses to characterize the 3D models of each specimen. We then explore the possibilities and advantages of this method for bedrock feature documentation and analyses. The Natufian graveyard at Raqefet Cave, Mount Carmel, serves as our case study.

Filini, Agapi (El Colegio de Michoacan) [91]
Symbols Are Important: Teotihuacan and Foreign Political Practice

Teotihuacan, the largest city in Mesoamerica, had developed a variable spatial interaction network which required reproduction in order to perpetuate itself. This paper suggests that symbolic acts (rituals and ceremonies), a distinct category of the state’s institutionalized practices, were instrumental in structuring the network and thus securing the success of Teotihuacan’s foreign political practice. Based on a GIS approach, the material manifestations of symbolic acts are explored to allow for the definition of social differentiation, and a consideration of how “otherness” was defined and of the effects of symbols on the local social fabric.

Idiosyncratic and Individualizing Traits Used by Mayan Artist to Punctually Qualify the Portrait (Facial and Head Treatment) of the Ruler during the Reign of K’ínich Janaab’ Pakal of Palenque (A.D. 615–683).

The city of Palenque, achieved its greatest splendor when it became one of the foremost centers in the Maya world during the reign of K’ínich Janaab’ Pakal (A.D. 615–683). Refined craftsmen used different media to create a repertoire of portraits of their rulers, heirs and courtly members. Although Mayan artists bear with different epigraphic resources to indicate the individuality of the represented personages, they complemented the image of each human being with a series of idiosyncratic and individualizing traits to punctually qualify the individual and to lead the observer to recognize who or what kind of person was characterized in the image. By placing the individual in his context and environment, analyzing the traits that shears with his collectivity and those of his individuality, will lead us to discover its proper identity. In this work, we will discuss different aspects linked to the inherent complexity of the notion of person and its representation. Thanks to the number of examples that Janaab’ Pakal left of his image we can examine portraits (facial and head treatment) of his youth as well as his mature years created by Palenque artists.

Finlay, Nyree

Kid-Knapped Knowledge: Emergent Sociality and Stories of Skill and Stone

Within lithic studies, the identification of kid-knapped products and an engagement with skill has offered identifiable signatures to explore how self and stone become imbricated in a number of ways. Along with experimental methodologies, such studies have provided powerful insights with which to explore the interplay of emergent identities in various knapping techniques and in diverse lithic raw materials. The main aim of this paper is to offer an overview of, and commentary on, interpretative narratives around the recognition of children’s stone working practices. Attention will also be given to if, and how, overarching narratives have changed over time and in light of recent studies. What are the wider lessons for the future of the archaeological child? Using examples from prehistoric Europe and Mesolithic assemblages, issues of gender, age and other aspects of personhood will be highlighted through a focus on the sentient and relational properties of lithic technology.

Raising the Roof: A Corbel Vaulted Roof at a Maya Commoner Household: Structure B-2 of the Medicinal Trail Community

This poster presents evidence for a corbel vaulted roof from a small Maya hinterland commoner structure. Initially used in elite tombs, corbel vaults eventually are used for a variety of structural features such as temples, palaces, and residences. By the Late Classic they are found in abundance in urban settings, most closely associated with the elites. Corbel vaulting is an expensive construction technique in terms of labor as they require thick walls supporting walls, and large amounts of cut stone. Moreover, they require access to the necessary engineering knowledge to be properly constructed. Medicinal Trail is a hinterland commoner community in Northwestern Belize, and Structure B-2 is a residential structure at the Tapir Group, a formal household within the community. Exceedingly rare for small commoner households, Structure B-2 was constructed with a corbel vaulted roof. Evidence for complex architecture of this sort within a commoner setting demonstrates the complex and integrated role small peripheral communities played in the larger Maya interaction sphere.

Fisher, Kevin (University of British Columbia)

Differing Trajectories of Urbanism on Late Bronze Age Cyprus

The Late Bronze Age on Cyprus was a period of revolutionary social change in which the island transformed from a relatively egalitarian, village-based society to one with hierarchical and heterarchical social structures. The Kalavasos and Maroni Built Environments (KAMBE) Project seeks to understand the relationship between these developments and contemporaneous changes to the built environment, including new forms of domestic and mortuary architecture, monumental construction, and the island’s first urban centers. Using both large-scale and more focused, high-resolution archaeological geophysics combined with test excavations, the project has been investigating the important Late Bronze Age sites of Kalavasos-Ayios Dhimitrios and Maroni-Vournes/Tsaroukkas. This work is providing important new
insights into the urban fabric of these early cities, revealing contrasting patterns of spatial production. While Kalavasos appears to have a planned and relatively nucleated urban form, the evidence from Maroni reveals a low-density cityscape with multiple nuclei. An attempt is made to explain these divergent trajectories of urbanism by considering the differing site histories of Kalavasos and Maroni during the Late Bronze Age and the place-making strategies by which their respective elites attempted to consolidate their power.

Landscape Architects’ Embellishments of the Ancestral Pueblo Record: Taking Liberties with the Unknown

Some southwestern landscape architects have generated minor variations on details of Ancestral Pueblo culture history. Their intriguing suggestions appear to be reflections of their unique professional training and perspectives. In this paper a sample of these creative ideas is critiqued.

A Neolithic Landscape on the Swabian Alb (Germany): Contributions of a Regional Approach

Building on the Southwest German Regional Archaeological Survey Project initiated by Mike Jochim, a project was launched in 2001 to explore Stone Age land use and settlement on the Swabian Alb limestone plateau, just 40 km north of the Federsee lake. This contrasting geographic area, rich in stone raw material but largely lacking in surface water, is well known to Paleolithic and Mesolithic researchers for its deeply stratified cave and rockshelter deposits in steep-sided valleys cutting into the plateau. The plateau surface itself has seen little archaeological investigation, though dense stone artifact concentrations were reported by avocational archaeologists. Results of archaeological survey, analysis of well-documented private collections, and subsequent remote sensing and test excavation document a rich Neolithic landscape on the plateau, including both settlement and chert-acquisition features dating to Early, Middle and later Neolithic time periods. In this paper we begin to assess contributions of this regional approach to broader understandings of Neolithic settlement in southwestern Germany. We focus on the value of the regional approach for placing a Neolithic chert quarry in a broader context and for exploring geographic diversity in Early Neolithic (LBK) settlement.

Fisher, Jacob (CSU Sacramento)

Methodological Considerations for Computing NISP: A Case Study from the White Mountains, California

The debate regarding the underlying motivations for large game hunting in western North America has ensued in American Antiquity for over a decade. Empirical support for the original argument for costly signaling hunting by Hildebrandt and McGuire largely was derived from a regional synthesis of faunal data from southeastern California that demonstrated a spike in artiodactyl hunting during the Middle Archaic. This spike is primarily driven by the faunal assemblage from a single, high-elevation site in the White Mountains of southeastern California. It was suspected that this anomaly was a reflection of analytical discrepancies in taxonomic identifications arising from different levels of experience among faunal analysts. Contrary to expectations, it was discovered that taxonomic identifications were actually conservative. Instead, the previously reported NISP for artiodactyls was calculated in a manner inconsistent with other analyses in the region. When the corrected values for the measure are used, the regional data show that the pattern of faunal exploitation is consistent with expectations derived from optimal foraging theory.

Fisher, Christopher (Colorado State University)

New Perspectives on Mosquitia Prehistory Using Lidar

The Mosquitia region of Honduras, long known to be an important archaeological region, has seen relatively little archaeological research. Here we present results from a project which has used LiDAR to document the cultural and ecological heritage of three previously undocumented areas within the region. These results include two large urban centers and numerous smaller settlements embedded within a human engineered landscape including terraces, canals, and roads. This record comprises a significant database that provides critical baseline data for modern conservation and preservation efforts.

[341] "The Poorness of the Soil Takes Away Hope": Resolving Ethnohistoric and Archaeological Evidence for Food Security in the Northern Maya Lowlands

Ethnohistoric accounts written by Spaniards in Yucatán during the 16th and 17th centuries suggest that food security was a major concern, one allegedly shared across ethnicities to include the Spaniards’ Maya informants. However, Maya communities had long been successfully producing food in Yucatán’s supposedly harsh conditions (and continue to do so). In this paper I offer a critical reading of select ethnohistoric accounts of the Yucatec Maya to make a case that, both overtly and subtly, these narratives indicate that northern Lowland Maya food security was vitally linked to the relationship between houses and gardens. This phenomenon is by no means limited to the post-contact Maya. Archaeological evidence from sites in the region, including Mayapán, Chunchucmil, and Yaxuná, demonstrate that the vital link between house and garden has considerable time depth in the northern Maya Lowlands. Ultimately, this particular reading of ethnohistory and its pairing with archaeological evidence will demonstrate that 1) there is evidence that Maya informants deliberately manipulated Spaniards' preoccupations with drought and famine for political ends, and 2) the relationship between houses and gardens was essential to food security and the success of low-density Maya cities long before the Spanish arrived.

Fitton, Hannah (Colgate University) and Therese Christiansen (Colgate University)

[172] The Brunk Site: The Public Outreach Efforts of an Oneida Archaeological Site in Central New York

The Brunk Site, a late sixteenth-century Oneida Iroquois village in Central New York State, provides a collaborative archaeological opportunity for Colgate students to learn from regional avocational archaeologists who have relevant experience and knowledge from their years of fieldwork and reporting. This poster details the public outreach efforts that the Brunk Site has facilitated by building relationships with community members and providing educational resources for children. Students are involved in this community archaeology through "Field Methods and Interpretations in Archaeology" led by Professor Jordan Kerber where they acquire first-hand knowledge about proper excavation skills and laboratory techniques. This course strengthens the community-university relationship, and the student research papers are a lasting contribution to the body of knowledge about the Brunk Site and Oneida archaeology. We created an exhibition, to be located on the Brunk Site in the future, introducing elementary-aged children to archaeology and Oneida sites. The exhibition discusses general archaeological practice and recovered materials from the site, as well as an overview of the diet, subsistence, and technological activities of the Oneida. The public outreach of the Brunk Site encompasses numerous members from all age groups through both the archaeological and educational efforts.

Fitts, Mary (University of North Carolina at Chapel Hill)

The subject of population movements has received renewed attention from archaeologists in the past few decades after being avoided by mid-twentieth century scholars. These new approaches incorporate ethnographic findings and stress the importance of investigating population movement as a process. Despite the increased sophistication of these models, the attempt to conceive population movement as a generalized phenomenon has, perhaps counter intuitively, limited their utility. After reflecting on a set of variables relevant to studying population movements and their effects, I focus on size of relocating party and motivation for relocation as two variables for differentiating categories of population movement with respect to expected behaviors and associated archaeological patterning. To examine the particular case of community relocation under duress, I consider the ethnohistory and archaeology of the Cheraw during the seventeenth and eighteenth centuries. This polity was one of many in the Southeast to respond to conditions precipitated by the Indian slave trade with mobility and the development of confederations. Comparisons of Cheraw settlement locations, ceramic production, and foodways from towns inhabited before and after multiple relocations in the eighteenth century suggest population movements in response to violent conditions will produce different archaeological patterning than those undertaken for opportunistic purposes.

Fitzgerald, Cassandra

The research areas of forensic and biological anthropology utilize the study of human remains to answer
questions in a medicolegal or archaeological context. Human remains are studied to reveal the age, sex, stature, and ancestry of an individual. Rogers (1999) created a method to determine the sex of modern-day individuals utilizing the distal end of the humerus, with a 92 percent accuracy rate. To expand Rogers' research, a larger blind test of the method with modern and prehistoric individuals was conducted. It is important to apply blind tests to new methods in order to meet the standards established in Federal Rules of Evidence 702 for scientifically sound and unbiased testimony in a court case. In cases where much of the skeleton is missing or destroyed, it is hoped that this study will confirm another reliable method for determining sex using the bones that may still be available to the archaeology and forensic communities.

Fitzhugh, Ben (University of Washington)  
A growing number of studies show how archaeological research can examine the long-term sustainability (and unsustainability) of past human practices, sometimes with implications for modern land-use planning. This paper explores this theme through a comparative analysis of archaeological settlement data from the Kuril and Aleutian Islands of the North Pacific Rim. These islands were occupied by maritime hunter- gatherers throughout the Late Holocene (Early / Middle Holocene in some areas). While the Aleutians were settled by a single cultural tradition that persisted to the 18th century with limited outside influence, the Kurils were occupied by a succession of three groups, separated by large scale depopulation / abandonment before the next wave of settlement. Settlement pattern data from remote areas of both archipelagos reveal similarities and differences in orientation to risky land/sea- scapes that are used to evaluate the hypothesis that geographical and ecological differences led to more and less resilient occupations.

[181]  Building a State One Stone at a Time: Architectural Energetics and Early State Formation in the Bronze Age Argolid  
Prior to the appearance of the first palaces at Mycenae in the 15th century B.C., the most impressive architectural manifestation of elite authority in the Argolid was not the palace or the house, but rather the tomb, specifically the shaft grave and the tholos tomb. While the funerary data supplied by these burials have long served as the primary means by which the study of Early Mycenaean state formation has been approached, such studies focus almost exclusively on the grave goods themselves rather than the tombs that housed them. This paper seeks to address this lacuna by applying an energetics approach to the funerary landscape, an approach that posits that the quantity of labor expended upon any particular architectural project correlates with the sociopolitical complexity of the society that produced it. Since one aspect of sociopolitical power is defined by differential access to labor resources, the values thus generated serve as quantifiable and easily comparable measures of the power of those groups responsible for their undertaking. This approach injects a new, yet rarely considered dimension to current discussions of “wealth” and “status” and offers new insight into the nature of the socio-political transformations that transpired during the Early Mycenaean Period.

[141]  Social Syntax: A Framework for Understanding Community Reorganization at Homol’ovi I  
Understanding internal population dynamics in the Pueblo Southwest requires the concurrent analysis of
architectural and depositional data. This requires the development of a theoretical framework capable of addressing the unique configuration of activities occurring during site reorganization and depopulation. To accomplish this, I combine aspects of spatial syntax, practice theory, and the life history model from behavioral archaeology. The use of three theoretical approaches addresses the weaknesses inherent in any individual framework. Specifically, practice theory and the life history model provide the missing pieces necessary to make extrapolations from the spatial syntax framework tenable. Using this framework, I analyze the internal demographic shifts within the 700s room block of Homol'ovi I, a Pueblo IV period site located in northeastern Arizona. This involves the examination of room use, depositional behavior, and architectural shifts revealing interesting shifts in room use, the utilization of multiple modes of closure, and repeated changes to access patterns. This theoretical and methodological framework produces a clearer understanding of social structure at the community level and highlights the complex reorganization processes occurring in the 700s room block of Homol'ovi I.

Fladeboe, Randee (University of Florida)

Macaw Technology in the American Southwest

Across the ancient American Southwest, imported macaws were material resources requiring a specialized technology. By technology, I mean the knowledge, tools, techniques and material contexts that enabled utilizing macaws for their intended functions, including ritual purposes. This paper deals with aspects of macaw technology, including the transport and care of live birds from the tropical south to a desert environment. The macaw, like all things, is itself an assembly of essential elements. Bones, feathers, appendages, and colors are all critical components of that assemblage. As a living organism, the bird is a dynamic material, always in motion and changing over time and space. As the macaws were moved from place to place, their particular assemblages were influenced by cultural and ecological parameters. Macaw burials and the fragmentation and dispersal of feather artifacts and images of macaws in pottery, murals, and rock art are indexes of the birds, each traveling on a separate itinerary. These factors contribute to understanding the technological practices concerning macaws and related birds.

Flanagan, Kelin (Florida Atlantic University) and Clifford T. Brown (Florida Atlantic University)

The Topology of Archaeological Site Distributions: Lacunarity and Fractal Dimension.

We are studying distributions of archaeological sites to evaluate the effectiveness and efficiency of survey methods, among other goals. We use two mathematical measures to describe the topology of site distributions: lacunarity (Λ) and fractal dimension (Df). Lacunarity is a measure that tells us about the sizes of gaps in a distribution at different scales, which relates directly to the probability that a transect will intersect a site. Although lacunarity was originally developed as a complement to fractal analysis, it is not itself a fractal technique and can be applied to any pattern. We use the gliding box algorithm. Fractal dimension is a parameter of fractal patterns, which are complex patterns exhibiting self-similarity and power-law scaling. We test for fractality and estimate dimension using the box-counting technique. As our test case, we are using maps of archaeological site distributions published for the Valley of Oaxaca, Mexico, because they constitute a very complete and detailed data set that, moreover, has become the canonical data set for the study of site distributions due to its use by Plog (1976) and, subsequently, Orton (2000). To date, we have found the distributions to be fractal with dimensions in the Df :: 1.46-150 range.

Fleisher, Jeffrey (Rice University)

On the Issue of Scale on the Eastern African Swahili Coast

This paper critically examines the issue of scale for second-millennium A.D. eastern African Swahili towns. Scale underlies many of the definitions of urban places with an emphasis on settlement size and concomitant implications for the incorporation of a rural hinterland. Medieval Swahili towns have 'big' reputations, renowned for their monumental architecture and long-distance trade even though they tend, in the main, to be quite 'small' places. In general, Swahili towns were extremely compact in size, with most less than 15 ha, and many of the most elaborate less than 10 ha. The small scale of Swahili towns, we argue, troubles the way they fit into classic definitions, especially with regard to the nature of food and craft production and implications of 'smallness' for social relations among town residents. Our current research at Songo Mnara, a 15th-16th century town on the southern Tanzanian coast, will serve as a basis to discuss these issues.

[53] Skeletal Tuberculosis Infection of the Hip? A Literature Review and Case Study of a Prehistoric North American Dog from Middle Tennessee

Close interaction between humans and animals are conducive to the spread of zoonoses, infectious diseases that can be shared among different animal genera and species. Bacterial zoonotic pathogens, including various types of tuberculosis (Mycobacterium sp.), can lead to infections affecting an animal’s skeleton. This is of interest and utility to researchers given the typical lack of preservation among non-bony bodily tissues in many archaeological contexts. I review the medical, veterinary, and archaeological literature concerning skeletal tuberculosis to provide a basis on which to explore the severe hind limb pathologies exhibited by a Late Archaic period domestic dog from the Fernvale site (40WM51) in middle Tennessee.

Fleming, Miranda (University of North Carolina Greensboro)
[231] Spindle Whorls and Spinning Technology as Indications of Ethnic Difference on the Wari-Tiwanaku Frontier, Moquegua, Peru.

In this poster, I describe spindle whorls from the Wari sites of Cerro Baúl and Cerro Mejía and their technological differences. The two Middle Horizon (500-1000 CE) sites are in a frontier region, located in Moquegua, Peru that the Wari shared with the Tiwanaku polity. Recent research suggests that these two sites may have been composed of multiple groups from different regions and to have interacted with local, as well as, Tiwanaku communities. This study will test this suggestion by looking at spinning technology as a possible indicator of ethnic difference. Since spinning was learned at an early age in a ‘community of practice’ and the practice relies on unconscious motor skills that would be difficult to change if a person became a member of a different community of practice (such as may be the case with patrilocal marriage). I compare spindle whorls from the two sites to determine if ethnic differences are present and compare these examples to spindle whorls found in the two polities. By combining these methods and applying practice theory to examine ethnic and technological differences in this frontier region, I explore the potential relationship between Wari and Tiwanaku affiliated people in Moquegua.

Flood, Jonathan (George Mason University)
[17] Settlement Continuity and Change on the Mochlos Plain in East Crete

The Mochlos plain—a series of eight parallel watersheds hemmed in by two horsts, the rugged peaks of the Orno mountains, and the Mediterranean Sea—has a settlement history spanning nearly five thousand years. Despite long- and short-term environmental changes, which include the gradual subsidence of the plain, aridization, eustatic sea-level change, erosion, volcanic ash-fall, declining water resources, earthquakes, drought, Little Ice Age events, and human impacts, settlement location, size, and site function has remained remarkably consistent over millennia. This paper explores the link between societal stability and site location, settlement morphology, and land-use. The overarching goal of this study is to posit and scrutinize the concept of settlement steady-states within spatially defined environments. The paper begins with an overview of the resource potentials and limitations within each of the eight watersheds based on pedology, hydrology, relief, and geochemistry. Then the diachronic trends in settlement systems are discussed for each watershed, beginning with the Early Bronze Age (2900 B.C.E.) inhabitants and continuing to the present. The paper concludes by integrating available paleo- and historical environmental information into the settlement model and then identifies and attempts to explain the consistencies and differences in human spatial behavior.
Linga as Stupa: Shaivite/Buddhist Material Syncretism in South Asia in the 1st Millennium C.E.

During the 1st millennium C.E. in South Asia, Shaivites (devotees of the Hindu god Shiva) slowly drew devotees away from Buddhism. In part, this process was facilitated by a gradual shift in the forms of the primary material symbols of Buddhist and Shaivite ritual. At the start of the 1st millennium C.E., Buddhists focused their ritual devotions on stupas, stylized representations of the Buddha's burial mound. Shaivites, on the other hand, focused their ritual devotions on linga, iconic depictions of Shiva in the form of a phallus. Over the course of the 1st millennium C.E., Buddhists slowly transformed their ritual foci into Buddha images. At the same time, Shaivites slowly abstracted the form of linga until, in the 7th century C.E., linga strongly resembled early Buddhist stupas. By gradually appropriating the primary material symbol of early Buddhism, Shaivites drew Buddhist devotees to a new faith. In a broader sense, the material evolution of the Shiva linga in the 1st millennium C.E. serves as an example of material transformations enacting spiritual transformations.

Calakmul, Oxpemul and Coba: Hydraulic Patterning on the Karstic Meso and Northern Plain of the Peninsula of Yucatan, Mexico

Settlement pattern research during the past 40 years in the Maya area has revealed a similar surface water management pattern in Calakmul and Oxpemul, Campeche and Coba, Quintana Roo, Mexico including a four step process to capture, retain, redistribute and discharge excess amounts of this element essential to their existence.

Foley, Kathleen (University of Wisconsin-Oshkosh)

Preliminary Analysis of the Karow Site Human Remains

The Karow site (A.D. 1300-1450) is located on the western shore of Lake Winnebago at North Asylum Bay in Winnebago Co, Wisconsin, and was excavated by Arthur Kannenberg and L.J. Dattt in 1932, after which the human skeletal remains and associated artifacts were donated to the Milwaukee Public Museum. This paper presents a summary of the initial analysis of those human remains and is part of a larger on-going research project into late prehistory in Wisconsin.

Follensbee, Billie (Missouri State University)

How Essentializing Essentially Leads to the Wrong Conclusions: The Varied Roles of Female Olmec and Olmec-Related Figures

The blocky, apparently sexually ambiguous bodies of large stone, Formative period anthropomorphic sculpture have led many past scholars to assume that Gulf Coast Olmec and Olmec-related figures largely or exclusively represent adult male elites. Over the past two decades, however, systematic studies have increasingly revealed that not only do Olmec sculptures display identifiably sexes and gendered features and accouterments, but also age-related features that reveal juvenile, adolescent, and elderly individuals. Upon the recognition that some Olmec and Olmec-related images represent female individuals, a number of scholars concluded that such female figures must represent exogamous brides who served to help establish and empower patriarchies. This is a plausible explanation for some figures, as exogamy was a fairly common practice in later Mesoamerica, and a number of these Olmec images show close correlations with conventional depictions of exogamous brides from other Mesoamerican cultures. Nevertheless, analysis of other sculptures illustrates that these female images vary greatly and assume a wide variety of powerful roles that cannot be so summarily explained. This presentation explores these issues, revealing how immediately essentializing all of these representations as depictions of exogamous brides or marriage-related scenes is far too hasty of a conclusion.

Hearth and Heated-Rock Cooking Structures: Diet Preferences and Differences in Consumed Foods Processing among the Hunters-Gatherers-Fishers in Baja California

One of the key archaeological elements in the coastal preparation and food consumption camps are hearths. Along the Baja California peninsula, there are different spaces or stone structures whose main
characteristic is the trace left by fire. Its morphology is varied and relative to the specific use/function for
the preparation of different foods, for their consumption or the conservation method (salting, smoked or
dried) to which they were destined. In this presentation we discuss some relationships between different
types of hearths and heated-rock cooking structures as well as malacological and osteological materials
associated with them that were found in the northwestern coast of Baja California. Some of the factors
analyzed include the design of the hearths and other heated-rock cooking structures, the kind of fuel
used, and the trace patterns —cut up, broiling, boiling, incineration, baking— related with the processing of
the remains. The final goal is not to create a typology, but an interdisciplinary study of archaeological and
biological evidence contrasted with ethnohistoric testimonies that allow us to suggest some diet
preferences and differences in food processing among the hunters-gatherers-fishers who occupied the
study area during the archaic and the late prehistoric periods.

Preliminary Analysis of the Hanna’s Town Legacy Collection: Life in an 18th century
Pennsylvania Town

Four decades of archaeologists, both professional and avocational, have excavated the site of Hanna’s
Town, Pennsylvania (ca. 1769–1810), resulting in nearly one million artifacts and tens of linear feet of
documentation. Since 2010, staff and students of the Indiana University of Pennsylvania Anthropology
Department have been working to create a computerized database and GIS of these data. This work is
ongoing, but sufficient data have been digitized to allow preliminary analysis. That analysis, presented
here, deals with the spatial arrangement of the site, taphonomic and collection patterns, access to
goods on the frontier, the presence of specific ethnic groups, and evidence of the Revolutionary War
raid that destroyed much of the town. The results of this analysis will lead to hypotheses that can be
tested once all of the data are digitized.

Ford, Anabel (UCSB) and Keith Clarke (Geography UCSB)

Using Cutting-edge LiDAR at El Pilar Belize-Guatemala—There Is Still a Need for Archaeologists!
LiDAR, a remote sensing instrument capable of penetrating vegetation, is creating a shift in
Mesoamerican archaeology that will transform research in forested areas worldwide. The Maya Forest
Alliance recently received a gift of LiDAR imagery covering the 20 km² El Pilar Archaeological Reserve in
Belize and Guatemala. High-resolution data were gathered on the forest canopy and ground surface in a
“point cloud.” We are identifying features using a new algorithm with superior LiDAR processing results
for cultural features. LiDAR results must be interpreted and validated in the field. We are field-validating
features to devise a protocol for the production of a topographic and cultural map of El Pilar. Unusual
features, such as a “citadel” and a sunken plaza connecting the offset causeways, have been detected
that were never recorded before. These discoveries change our understanding of ancient Maya land use
and the city of El Pilar, but their existence and scope can only be proven by field validation. Our 2013 field
set the stage for our discovery strategy to confirm the nature of features illuminated in LiDAR imagery,
setting up a protocol recording the characteristics on the landscapes to share with others working with
such imagery.

Forde, Jamie

Residential Excavations at the Pueblo Viejo of San Miguel Achiuta: Preliminary Results
This paper presents preliminary results of an excavation project carried out in the “Pueblo Viejo” of San
Miguel Achiuta, located in the Mixteca Alta region of Oaxaca. Achiuta was an important religious center
during the Postclassic period, and site of considerable conflict with colonial authorities throughout the
16th century. Intensive horizontal excavations were conducted at three residential terraces within the
center of the site to investigate indigenous domestic life during these time periods. Further, one sounding
unit was placed into a feature associated with an obsidian workshop to examine issues of political
economy.
While this paper provides a summary of all the above research, focus is placed most heavily on data recovered from an indigenous elite residence located within the monumental core of the site. Recovered artifacts and construction sequences reveal how native elites occupied this space well into the 16th Century, if not beyond, and simultaneously maintained links with the pre-Hispanic past while appropriating certain aspects of European culture. Data suggest that indigenous authority at the site was retained—perhaps in unexpected ways—amidst dramatic conflict and upheaval during colonial times.

What Is Up There? An Introduction to Common Issues with the Use of Hilltop Settlement Concept in Archaeology

The term "hilltop settlement" is employed, in archaeology, as a common word to qualify any site located on a natural or artificial elevation. As an introduction to this symposium, we examine, through different examples taken in both Old and New World cultures, the occurrence of this concept in the archaeological literature, and try to analyze how it is employed: as a simple landscape and empirical appreciation and/or for socio-political assumptions. We present the different functions assigned to hilltop sites, from the most common (defense, strategic locations) to the less frequent ones (ideological conceptions, environmental concerns). This review leads us to one clear observation: the variety of functions and their superposition generate a very complex and nebulous field of research. In this situation, what alternatives are offered to archaeologists? If a standardization of study methodologies and classifications is quite ambitious, an epistemological approach is accessible. We suggest that future work conducted on hilltop sites consider more systematically their multiple dimensions, as well as the potential and limits of these dimensions.

Hiding in Plain Sight: Gendered Strategies of Survival and Subterfuge along the Migrant Trail

Over the last decade, the number of undocumented female migrants crossing from Mexico into the United States through the southern Arizona desert has dramatically increased. Still, little anthropological research has explicitly focused on the experiences of these women or the influence that gender has on how people prepare for desert border crossings. Since 2009, the Undocumented Migration Project has drawn on the fields of archaeology, ethnography, and forensic science to explore the varied experiences of different sub-populations of migrants and to highlight the many forms of violence that characterize the crossing process. In this poster we discuss the role of gender in the migration process and the unique material culture that women often employ as they attempt to cross the border, evade Border Patrol, and survive the desert. We juxtapose our analysis of gendered artifacts with border crossing narratives collected from women and men over the last five years. We argue that gender identity and certain female strategies of desert survival are not easily recovered in the archaeological record. We also discuss the implications of these findings and their relevance to archaeological studies of women in historic and prehistoric migrations.

Forte, Maurizio (Duke University)

New Perspectives in Cyber-Archaeology: Simulation and Immersive Environments

The paper wants to explore new ways of virtual representation and 3D interaction with archaeological data captured during archaeological excavations. The broad use of 3D systems and technologies of data capturing (computer vision, laser scanning, 3D photogrammetry, remote sensing) has substantially increased quantity and quality of 3D archaeological data.

Nevertheless, a very important and quite unexplored research field is represented by immersive and semi-immersive visualization systems, such as CAVEs (Cave Automatic Virtual Environment), holographic
displays, head mounted displays associated with virtual reality applications. Duke University started a new research program aimed at experimenting new forms of visual immersive interaction with multiple devices such as Z-Space, Oculus VR, DiVE (Duke Immersive Visualization System) in archaeology but sharing a common software platform. The first tests have been with the architectural stratigraphy of the Neolithic site of Catalhoyuk.

Postconquest Technological Innovation and Outcomes in Ceramic Traditions in Central Mesoamerica

Indigenous ceramic traditions experienced differing changes in the aftermath of the Spanish Conquest of Mesoamerica. In the Mexican central highlands, we draw information from several well documented case studies: the cities of Tenochtitlan-Tlatelolco, the Otumba area, and two neighboring sites in the contemporary state of Hidalgo. Our studies contribute to a better understanding of hybridization processes resulting in innovations, and consequences of technological processes on ceramic wares. We propose that transformations and stability are related to a new economic scenario, resulting from changes in workshops and market networks after the conquest, and the persistence of preconquest consumption trends among marginal indigenous communities.

They Also Dug: Early Women Archaeologists in Northern New Mexico

Linda Cordell had a lifelong interest in the careers of women in archaeology and especially those early pioneers who preceded her in working in northern New Mexico. She felt that their work was often overlooked at the time, as were their overall contributions to Southwest prehistory. We review the careers of several early women archaeologists, including Ethel Nelson, Lucy Wilson, Bertha Dutton, Margorie Lambert and Agnes Simms, noting some of the sites/projects in which they were involved, the difficulties they encountered, their successes, and the overall impacts of their collected efforts on the Southwest prehistory of their times as well as today.

Colorado River Archaeological Projects, 1956 to 1985: From Salvage to CRM

The Colorado River is the most controlled river in the United States. Major and minor dams and related facilities provide irrigation and municipal water and electricity to forty million people in the American West. Congressional authorization of four major dams triggered large-scale salvage projects between 1956 and 1985—Flaming Gorge, Glen Canyon, Navajo Reservoir and McFee (Dolores Project). The first three were supported by Bureau of Reclamation (BOR) funds channeled through the National Park Service; the fourth was funded directly by the BOR. An overview history of the projects is provided together with a discussion of the legacy of the projects for subsequent American and foreign (especially Egyptian and Nubian) archaeological practices.

You Call It Nequepio, We Call It Cuscatlan: A Sixteenth-Century Parallel for Precolumbian Interaction in Southeastern Mesoamerica

The relationships between early sixteenth-century bands of Spanish conquistadors in southeastern Mesoamerica have received little attention from historians and virtually none from archaeologists. The historically documented interactions between these groups operating in El Salvador, Honduras, and Nicaragua in the 1520s provide some clues for modeling routes of communication, networks of
interaction, and levels of interconnections in earlier times. Some degree of Precolumbian interaction throughout the southeastern Mesoamerican region has long been suggested by exotic portable objects and mutual influences in art styles and architecture. A close look at early conquistador interaction in the region reveals a number of parameters and possibilities with regard to routes of communication and interaction. A case study is provided by Hernando de Soto’s invasion in early 1525 of the Pipil center of Cuscatlan, central El Salvador, from León, Nicaragua. Cuscatlan, known as Nequepio to the Chorotegas in Nicaragua, at this time marked the southeastern frontier of Pedro de Alvarado’s extension of the conquest of Mexico. The Lenca territory of eastern El Salvador, between the Lempa River and the Gulf of Fonseca, formed the corridor between Nicaragua and Cuscatlan-Nequepio and a conduit to the Choluteca region of Honduras.

[179] An Experimental Project of Mud Men-and-Women, Ceramic Figurines Common in Household Production: Made Locally by the Household or a Specialist?

Crude, minimally-human, poorly fired figurines appear as a widespread conventionalized form in central Mexico in the Postclassic period. Called mud men-and-women at Xaltocan and ghosts in Morelos, they were used in households. Based on their appearance, one would not imagine these were made by a specialist's tools or firing facilities, but rather were homemade and fired in a hearth. Several hypotheses surround their purpose, ranging from serving as representations of earth beings and indexing a connection between the community and the land to the importance of the embodied experience of making the figurines. Chemical provenance analyses indicate that Xaltocan mud men-and-women are made from local clay, and they are often recovered in complete form sometimes in hearth contexts, lending support to household production. Yet could these figurines have been properly fired in a household hearth? In this paper, we report the results of an experimental archaeology project designed to replicate the household production of mud men-and-women. Our conclusions have important implication for the interpretation of the production and consumption of this poorly studied ceramic type.

[297] *Micromorphology and Site Formation at Yangguanzhai: A Preliminary Analysis of the Composition and Formation of a Yangshao Moat Deposit*

In order to gain further understanding of Neolithic midden activity and site formation in North-Central China, a micromorphological investigation was developed within a large refuse-filled anthropogenic trench surrounding a Miaodigou phase (6000-5500 cal. yrs B.P.) village in the Wei River Valley, Shaanxi, China. The study consists of the detailed mapping of stratigraphy and localized sampling in the most representative portion of the deposit. Currently, a majority of local archaeologists refer to this feature as a "moat" and have interpreted this as either a defensive or symbolic feature that, once relict, was intentionally filled with refuse by secondary waste activity. Since the deposit contains dozens, if not hundreds, of discrete sedimentary units, it is clear that this feature had an extremely complex depositional history that cannot be fully understood by traditional excavations and in-field interpretations. Therefore, the aim of the research is twofold: (I) to identify the components of the deposit and their spatial relationships, and (II) provide a preliminary site formation model of the deposit that can be tested by further excavation and sampling.

[307] *From Ship Model to Site Formation Model: Using Historical, Archaeological, and Environmental Data to Model Shipwreck Deterioration*

The waters of the North Atlantic are littered with a variety of World War II shipwrecks. The merchant vessels, which supplied the Allied frontlines of World War II while keeping America fed during Germany’s guerre de course, comprise the majority of these sunken watercraft. This study considers the potential of
using archival sources (in particular ship builder’s plans) to create virtual ship models, and using three-
dimensional remote sensing datasets collected by NOAA’s Battle of the Atlantic Expedition between 2008
and 2013 in order to create individual multi-stage deterioration images to sample North Carolina’s World
War II merchantmen wreck sites. This interdisciplinary research considers both historical and geospatial
data, as well as environmental processes. It is hoped that an integrated predictive model designed to
visualize cumulative site formation data will inform management actions regarding long-term stewardship
of these wreck sites.

[B342] The Versatile Triangle: Exploring Intra-Type Variability of Projectile Points Using
Geometric Morphometrics

Borrowed from the field of biology, geometric morphometric analysis has been recently applied to lithic
assemblages with great success. This paper discusses the results of a 2D morphometric analysis of
triangle points from the Mohawk Valley, New York, the staple point form of the late pre-contact period.
This morphometric approach, which uses outline data extracted from high-resolution photos of the
projectile points, leverages multivariate statistical analysis to visualize intra-type variation present in the
collection. Change in shape (via length-width ratios) has been previously documented for this collection,
but this new application of morphometrics results is a more nuanced look into the nature of change
through time than that provided by traditional caliper-based methods. The result is a high-resolution
examination of morphological and thus technological variability and an example of an alternative
technique that offsets the inherent drawbacks of course-grained typological approaches to projectile point
characterization.

[B296] Archaeology Should Be Futuristic: Because Civilization Depends on It

For the past century, archaeologists have been the shepherds of the civilization concept, which has
effectively coalesced the concept with ancient statecraft, territorial “cultural-coherence”, and hegemonic
political economies. Theoretical turns throughout the 20th century, from World Systems to Practice
theory, have chipped at the canonical model of complexity underpinning the concept of civilization. Yet
the essential paradigm linking emergent civilization to large-scale production and political power has been
merely reclothed with little shift in the seminal civilization = state equation that defined core theoretical
tools throughout the last century. The 21st century abruptly ushered in a stark recognition that the
contours of civilization were not solely the terrain of states; dislocated and rogue forces shook the towers
of western economy, ideology, and politics and cast the modern civilization apparatus into turbid waters.
Today, in an era of unprecedented mobility, fluidity of identity, and non-Cartesian power networks,
archaeology must radically transform its understanding of its core concepts and question whether the
terrain of civilization that we see today was present also in the past. In a very real sense, archaeology
must look to the future to interrogate the past if we hope to better explain the human condition over the
longue duree. [B296] Chair

[B249] Where Obsidian Sourcing Isn’t Long-Distance Trade: Landscapes, Provisioning Strategies, and
Organization of Space

The terms “obsidian sourcing” and “long-distance trade” often seem considered virtually synonymous.
For example, recent work to develop obsidian sourcing at the quarry level (using magnetic parameters)
drew criticism from a reviewer: obsidian sourcing is devoted to reconstructing long-distance trade routes,
and identifying different quarries is irrelevant to that end. Such a view is extremely limited. Research in
the world’s most obsidian-rich natural and cultural landscapes, including the South Caucasus and the
Pacific Northwest of North America, allows obsidian sourcing to be used in different interpretive
frameworks. Sourcing artifacts at sites literally in the shadow of an obsidian-bearing volcano yields few, if
any, insights regarding long-distance trade. In such contexts, though, obsidian sourcing can instead
reveal behaviors linked to mobility, subsistence, land-use, and other social phenomena. Additionally, new
insights are possible with new techniques. For example, portable X-ray fluorescence (pXRF) can bring
traditionally lab-based studies to the field, enabling on-site collaborations, novel research designs, and
source data for many more artifacts than previously possible. Furthermore, magnetic studies can be
useful to isolate overlapping occupation levels, identify diachronic changes in lithic technology, and study the organization of living space at Paleolithic sites.

Franchetti, Fernando and Nuria Sugrañes (Conicet- Argentina)
Many studies have attempted to establish the relationship between form and function in the ceramics of different times and places. For example, these efforts have helped to explain how ceramic technology has been used by highly mobile human foragers. The sample presented here provides data from three different museum collections. Technological and design characteristics reveal a wide range of form and style, distinguishing these assemblages from those recovered through archaeological investigation. These data reveal the complexity of technological developments over a 2000 period, and from this complexity new problems arise: we see differences in spatial distribution and density, and we see change in both the use and exchange of pots. Such complexity demands further investigation. While some vessel forms (like cooking or storage pots) might be well-suited to locations organized around collection, production and caching, other forms (like plates and jars) were recovered showing broader uses of ceramics. Finally, the diversity of non-local styles reveals that pots were exchanged through highland corridors, between disparate groups on either side of the Andes.

[69] Raw Material Transport and Early Designs at the Southern End of the Deseado Massif (Patagonia, Argentina)
Early human occupations at the southernmost end of the Deseado Massif -La Gruta area- date from the Pleistocene/Holocene transition and are, according to the available evidence discontinuous in time. A little bit after that time, the presence of Mylodontidae and guanaco has been recorded at the area, although not clear evidence of strict contemporaneity in time and space between extinct fauna and humans have been found. Here we will discuss stratigraphic and surface evidences related to this early presence. Human inhabitants were transporting not only obsidian—from distances of ca. 175 km to the northwest—but also translucent chalcedony, available at distance of 25 km to the north. Preforms of projectile points recovered on surface and made on chalcedony, seem to have similarities in design, in one case, with an early point recovered at the south of the Magellan Strait, more than 400 km to the south. In other cases, they can probably be related to the range of variation of fish-tail projectile points, recovered in Patagonia, suggesting the existence of more than an early design of projectile points.

[20] A Cosmopolitanism of In-Betweens: Archaeology of Medieval Trade and Politics in Armenia
Medieval social life in Armenia and surrounding Transcaucasia has been multiply marginalized within historical discourses, imagined both as the periphery of cultural and political worlds centered elsewhere, and through the lens of emergent modern, capitalist subjectivity. Lost within these totalizing conversations are the experiences of subjects who were particular both to their region and their time. This paper summarizes the data and arguments of my doctoral research in the Kasakh Valley of Armenia, and reviews my investigations of late medieval (A.D. 1200-1400) trade and political practice. My research asks: How did actors differentially situated in medieval society undertake particular and locally-situated projects while simultaneously imagining their place in larger worlds linked by movement along the highways of the Silk Road? I explore this question using landscape survey results, epigraphic and historical evidence, and from my excavations at the Arai-Bazarjugh caravanserai, which was an assembly point for mobile subjects, localized political projects of architectural endowment, and circulating regimes of taste in cuisine and material culture. I draw on the concept of cosmopolitanism, defined as a make-do practice of working between totalities—a practice which unifies both my imagination of medieval subjects and my multiscalar methodological approach to medieval social life.

Mud and the Maya "Megadroughts": 2200 Years of Hydroclimate and Multiple Hazards from Northern Yucatan Stalagmite Records

The so-called "collapse" of the high civilization in the Maya lowlands during the Terminal Classic Period (TCP) is associated with severe and persistent megadroughts in the Yucatan. Previous work on the Chaac speleothem indicated that TCP climate included 8 severe droughts lasting 3-18 years from 800-950 C.E., alleviated by brief moist periods characterized by low oxygen isotope values. New data from a nearby annually layered multiproxy stalagmite record (CH-1) that was deposited between -200 B.C.E. and 2007 C.E. shows that the TCP in the northern Yucatan was plagued not only by drought, but also by multiple extreme climatic hazards. The calcite CH-1 stalagmite contains embedded mud layers during years when severe hurricane-induced cave flooding occurred. All 20th century flooding events CH-1 are associated with years of local hurricane rain events. The threshold for CH-1 mud layer emplacement varies with pre-existing hydrologic conditions; i.e., mud layers are less likely to be emplaced, even by severe storms, when persistent drought lowered the pre-existing water table (e.g., 1988s Hurricane Gilbert). CH-1 multiproxy data provide new evidence of multiple overlapping hazards during the TCP. Furthermore, the newly-recognized tropical cyclone masking effect has created a wet bias in the Chaac isotope-based paleo-rainfall proxy reconstruction. Implications are discussed.

Geochemical "Mass Sampling" of Ceramics by pXRF: Or, What to Do with All Those Sherds?

Rapid and cost-efficient mass sampling of archaeological ceramics using portable x-ray fluorescence (pXRF) spectrometry has potential to reveal compositional differences within and between ceramic assemblages that would otherwise be unclear in a limited program of individual analyses. A greater understanding of the total compositional variability of a ceramic assemblage is essential in order to study aspects of ceramic production, distribution, and the social systems involved in these processes. This poster presents the results of a pilot program of geochemical inventory, or mass sampling, of ceramic sherds from the midsequence deposits at the Sigatoka Sand Dunes, on the island of Viti Levu, Fiji. XRF analysis of all Fijian Plainware (2300-1500 cal B.P.) and Navatu (1500-1000 cal B.P.) sherds from individual excavation units reveals compositional similarities and differences that enhance our understanding of the technological shifts that occurred at the juncture of these time periods. As a research strategy, this differs from the focus in lithic studies on fine-grained elemental quantification; the ability of pXRF to "average" elemental concentrations within artifacts, and to generalize patterns within and between assemblages, allows for acquisition of large datasets more suitable for anthropological inquiry of ceramics.

Freeman, Andrea (University of Calgary)

Lessons from (the) Desert: Applying Geoarchaeology on Canadian Soil

My work at Desert Archaeology and as a consulting geoarchaeologist in Tucson during the period 1994-1997 gave me the tools to actively integrate my academic research into applied contexts using geoarchaeology. When I came to Calgary in 1997, and particularly when I was fortunate enough to purchase a large piece of coring equipment, I felt that the process would be easy. In this paper, I compare geoarchaeology and consulting archaeology in both contexts in an effort to demonstrate the differences in context, policy, and economics that hinder geoarchaeology in Alberta from being as actively accepted as it was in Tucson. I draw on both my own experience and the experience of my former students, and offer suggestions that may help to integrate geoarchaeology in CRM contexts in other parts of the world.

Freeman, Allyse (University of Wisconsin - Milwaukee)

Investigating Social Differentiation at the Formative Site Amalucan, Puebla, Mexico

Previous research directed by Melvin Fowler at Amalucan—a Formative (2500 B.C.- A.D. 200) site located in the Valley of Puebla, Mexico—documented a large water management system that operated from approximately 700 to 200 B.C., with numerous canals and two large impoundment areas. This system represents one of the most complex pre-urban water management systems in Mesoamerica.
While Fowler’s research provided a timeline of occupation and interpretation of water management systems, further work is needed to place Amalucan within a larger regional framework. The primary goal of the current study was to infer the degree of social differentiation at Amalucan, by using ceramics as markers for nascent class distinctions. Sherds collected in the 1960s were analyzed in order to assess the level of differentiation during the Middle-Late Formative. This research enhances our understanding of how Amalucan was related to other sites in the Puebla-Tlaxcala Valley in terms of both ceramic typologies and sociopolitical complexity.

Retelling an Ancient Story through Modern Technology: The Rock Art of Eagle Nest Canyon

The rock art of Eagle Nest Canyon in Val Verde County near Langtry, Texas consists primarily of Pecos River Style pictographs that were documented by Kirkland as early as 1935. During the 2013 joint Texas State University/Shumla Archaeological Research & Education Center field school, the pictographs were reexamined using new techniques and technologies. Students learned to apply these technologies in rock art research. These technologies included: a total station to record the provenience of the various figures, a tablet to record field observations in a database, a digital microscope (dino-lite) to examine stratigraphic relationships of the various figures and pigments, D-stretch to filter the colors of the pictograph pigments, Wacom Cintiques to produce digital illustrations of the figures, and Agisoft Professional Photoscan to produce three dimensional renderings of the rock art panels and shelters. This technology has enabled a detailed look at the panels that were not previously available.

Freidel, David (Washington University in St. Louis)

Frontier Centers and Salient Centers in the Late Preclassic Maya Lowlands

Interior frontiers and routes linking territories, both within the lowlands and beyond them, defined the political geography of the region from the Preclassic. Salient communities represented polities at a distance beyond their frontiers and were situated on such routes to facilitate trade in key commodities. The Central Karstic Uplands were the geographical heartland of the Preclassic lowlands and home to El Mirador and a constellation of related sites, probably the earliest lowland state. El Achiotal in northwestern Petén was a Frontier center of the Mirador state, between the Mirador uplands and the swampy riverine country to the west. Cerros was a Salient port on the Caribbean for the Mirador state, and Yaxuna was another Salient in north central Yucatan. All of these centers were on strategic trade routes linking the interior to the periphery. We outline the evidence supporting these arguments.

Reconsidering Ancient Population Movement in Mesoamerica: New Strontium and Oxygen Isotopes Values in Western Honduras

Strontium and oxygen isotope ratios in human tooth enamel indicate widespread population movement among the Classic period Maya, including migration into rural communities as well as large centers. Identifying migrants—and where they came from—requires an in-depth understanding of the isotopic variability in both the individual’s new residence and his or her homeland. This is particularly important for studies of sites like Copan, which is the major Maya urban center located at the interface between the Maya region and upper Central America. We present new strontium and oxygen isotope data for western Honduras that identify additional possible homelands for non-local individuals buried at Maya sites. Equally important is the potential for exploring migration patterns among diverse indigenous populations in Honduras, such as the Jicaque and Lenca. Thirty-four modern plant and animal samples from western Honduras have values similar to those identified in the Maya region, ranging from 0.704290 to 0.713519 87Sr/86Sr. Four geologic regions have distinct average values, with additional baseline data available from six oxygen isotope values collected from rivers and streams. We reconsider migration in published

Leveraging Water and Power at Tikal?

Our paper presents the results of applying the hydroarchaeological method to the central precinct of Tikal, Guatemala. This approach utilizes simulated daily paleoclimatic data, watershed modeling, and traditional archaeology to explore the functionality of Tikal's well-known reservoir system. Previous studies at Palenque revealed great potential for spatially-distributed watershed modeling in developing plausible scenarios of water use and supply, and the effect of extreme conditions (flood and drought).

The hydroarchaeological method produced simulated daily water levels for the reservoirs by calculating input (rainfall and runoff) versus output (usage, evaporation, and infiltration). Plausible answers to complex environmental questions often require tools (e.g., watershed modeling software) designed to study current and/or future impacts on landscapes. What quantities of water did the reservoirs maintain during periods of climatic normalcy? How did the reservoirs of Tikal respond to decadal drought? Answers to these and similar questions offer insight into broader questions, such as, what effect did fluctuations in water levels have on social organization and the elite power structure? The research presented here aims to provide a better understanding of the environmental and social impacts that Maya water manipulation strategies had on urban development at Tikal.

French, Katherine (New York University)

Interspecies Cremations in Anglo-Saxon Paganism: Local Practice or Multiregional Trend?

Martin Carver has recently argued that early medieval pagan ideology and practice, including mortuary ritual, were adapted to local conditions across northwest Europe. This paper will interrogate this hypothesis by analyzing regional variation in the practice of human and animal co-cremation burials in the Early Saxon period in England (ca. A.D. 450-650). By drawing on newly collected data from cemeteries and individual cremation burials in the Midlands in comparison to previously published contemporary cemeteries in other regions, this paper reviews all available evidence for interspecies cremation rituals. The new data presented will indicate that, while variation in corpse treatment and burial are indeed present, there are many more similarities in interspecies cremations across the landscape than has been previously argued. Finally, consideration will be given to the historical and archaeological evidence highlighting the importance of various animal species in the practice of early medieval paganism.

Obsidian Consumption, Social Dynamics, and Contrasting Value Regimes in the Prehistoric West Mediterranean

This presentation focuses on prehistoric obsidian circulation in the West Mediterranean from the 6th to 2nd millennia B.C. Since the field of study was inaugurated by Cann and Renfrew in 1964, scholars have generated a large amount of data on the character and use of the various obsidian sources. However, until now there have been few attempts to use these data to return to the broad archaeological questions that motivated the field’s initial scholars. In contrast, this paper views obsidian as a means to an end, a way to contextualize larger arenas of interaction, social dynamics, and contrasting value regimes. As such, this paper presents a diachronic overview of the history of obsidian use in the West Mediterranean, highlighting key issues surrounding the recognition of various exchange mechanisms in the archaeological record as well as the circumstances behind the development of large-scale obsidian exchange networks with the introduction of the first farmers to the area, and the contraction of these networks at the time of the first metalworking. The role of exchange in the maintenance of social relations across space is highlighted as well as the role of redistribution in the establishment and reification of elite power.

[312] The Big Role of Small Game in the Maya Lowlands

The ancient Maya exploited a full range of animals for food and ideological inspiration. Zooarchaeological data demonstrates that diverse mammalian and non-mammalian taxa were used in subsistence. However, the iconographic corpus of mammalian taxa is heavily weighted toward larger animals. This paper discusses the role of small animals in elite subsistence at the sites of El Perú-Waka’ and La Corona, Guatemala as revealed by recent zooarchaeological analyses. Elite structures at these sites demonstrate an abundance of small and medium (under 10 kg) mammals such as rodents and opossums. It is argued that the representations of deer prevalent in Maya iconography across the Lowlands is not reflective of everyday reality and instead demonstrates idealized food preference. In fact, the diversity of small taxa is conspicuous in its relative iconographic absence. This offers insight into ancient perceptions of value ascribed to particular animals and adds to the discussion of human-animal interactions.

[20] Attitudes towards Animals: Connections between Eurasian Animal Style art and the Representation of Animals in Southeastern Slovenia

The archaeological perspective on the transmission of knowledge may be subtly influenced by modern geopolitical relationships and boundaries. This has been the case in the Eastern Hallstatt culture, where meaningful connections with Central Europe as well as the Mediterranean are frequently sought. This is not to deny the existence of such connections in the Early Iron Age, however too often connections with more eastern regions, especially the steppes, are overlooked except as a source of invasion and social unrest. This reductionist perspective ignores the reality that weapon styles, horse gear, and horses themselves were being actively imported from the east. I examine steppe animal art and representations of animals from the Dolenjska Hallstatt culture of southeastern Slovenia to determine whether there may have been some shared modes of representation, and possibly conceptions of animals, circulating in the Early Iron Age that have been overlooked. I situate this examination with a discussion of the treatment of animals in the two areas to shed light on the tension between representation and practice.

[153] Recent Research Concerning the X-Ray Diffraction of Nicaraguan Ceramic Composition

In the past, reconstruction of the social identity of pre-Columbian Pacific Nicaragua has largely drawn from ethnohistoric sources, which suggest an aggressive indigenous population replacement by the Oto-Manguean language family (Chorotega) as they moved south into Nicaragua. While it may be stated with relative certainty that the migration of the Chorotegan speakers did in fact occur, recent archaeological research coupled with x-ray diffraction analysis of several pottery traditions from the region contend against the rapid replacement of the native population. The results of such research suggest that the gradual substitution of the existing indigenous red wares with a white-slipped polychrome variety was an internal development. It is the endeavor of further research concerning the x-ray diffraction of Nicaraguan ceramic composition to broaden the understanding of the intra-regional exchange and its consequences for social identity.

[143] Intersections of Age and Gender during the Indigenous Western Alaskan Bow and Arrow War Days

The Bow and Arrow War Days was a period of regional unrest in indigenous western Alaska. The tribal period of conflict may have started several hundred years ago, and it ended near the beginning of indigenous-colonial interactions in the early 1800s. Much of what we know about this intense time of warring comes from archaeological, ethnohistoric, and oral historic data. Yup'ik Eskimo villagers devoted substantial resources to preparing for enemy siege (a primary raiding tactic) and to sending parties out to attack other communities. Boys were trained in the arts of battle, and villages were organized to resist and outlast sieges. This paper will explore the roles and intersections of age and gender during this
period of conflict.

[30] “In Short, They Gave Us What They Had” (Henri Joutel, 1687): Plant Remains from the Wallace Bottom Site, Southeast Arkansas

Among his many achievements and contributions as Director of the Arkansas Archaeological Society, Tom Green facilitated both paleoethnobotanical and historical archaeological research. Having benefited from his efforts and in appreciation of his legacy, we report on archaeological plant remains from the Wallace Bottom site (3AR179) in southeastern Arkansas, a good candidate for the location of the late seventeenth-century Quapaw village of Osotouy and the first French Arkansas Post. We examine intra-site variability that might shed light on changing relationships and shifting economic strategies between native people and French traders through time. We focus on how plant food remains can reflect the roles and statuses of Quapaw women during the critical early decades when trade and general accommodations between these two societies and among others in the Mississippi Valley were being negotiated. The Wallace Bottom archaeobotanical assemblage is compared to those from other historic sites in the Mississippi Valley and U.S. Southeast in order to broaden perspectives on foodways and European-American Indian interactions during the colonial era.

[311] Chiriquí Mortuary Ritual at the Rivas-Panteón de la Reina Complex, Costa Rica

Chiriquí Period (A.D. 700-1500) cemeteries have been a subject of archaeological inquiry for more than a century. However, the activities associated with the preparation, burial, and maintenance of the deceased have been inferred only through the use of ethnographic and ethnohistoric accounts from the region. Excavations at the Chiriquí residential-mortuary complex of Rivas-Panteón de la Reina (A.D. 900-1300) revealed a series of spatially discrete architectural features including steps, causeways, pavements, and fire installations positioned sequentially between the village and the site’s cemeteries. The spatial organization and material patterning of the Rivas-La Reina complex provides compelling evidence for highly structured ritual activities that included the display of the deceased, processing of bodies, secondary burial, and grave visitation. These patterns closely resemble those described in 17th through early 20th century documentary accounts of Talamancan mortuary events.

[102] Osteological Analysis and Regional Comparison of a Mycenaean Burial from the site of Pefkakia near Volos, Greece

The site of Pefkakia on the southwestern shore of the Bay of Volos in Greece is an important settlement dating from the Neolithic to the Late Bronze Age. Current excavations have documented an expanding Mycenaean settlement beyond the limits of the Magoula-Pefkakia during the LHIII A. Since 2010, new excavations have revealed multiple late Mycenaean architectural remains, as well as three well- constructed tabular stone cists. The first two cists excavated in 2010 revealed only burnt faunal remains. In 2013, a single extended human burial was recovered from the third cist below and possibly predating a series of LHIII A2 architectural features. The skeleton is an older adult female without any grave offerings. While the basic biological profile provides insight into the individual’s status and life history, it is the various traumatic and pathological lesions on the skeleton that are unique and provide a rare glimpse of Mycenaean life at Pefkakia. Although the recent investigations produced only one burial, a comparison of this individual to remains from the adjacent Magoula-Pefkakia, as well as Dimini and other burial samples in the Volos region, will help us better understand the context and importance of this Late Bronze Age woman.

[202] Toward a Better Understanding of NAGPRA: Contributions by Linda Cordell

The Native American Graves Protection and Repatriation Act has had a profound impact on the relationship between archaeologists and American Indian tribes. NAGPRA required both to strive to understand in particular the meaning of “cultural affiliation,” which is still under discussion 23 years after the passage of the Act. Linda Cordell lent her expertise to the understanding of this and other concepts related to NAGPRA as well as their application. This paper will explore her contributions to NAGPRA implementation with contributions from agencies, institutions, and tribes that she worked with.

[117] CRM and Geoarchaeology at the Sentinel Gap site (45KT1362)

The inability to define on a broad scale landscapes with sediment sequences of appropriate age has severely limited purposeful surveys for Paleoindian archaeology. The recurring need to evaluate the chronostratigraphy of landforms on a case-by-case basis has made the search for the earliest Americans a time consuming and costly process across the American West. In the Pacific Northwest CRM-driven projects are responsible for most finds of early-dating sites. This paper examines the discovery of the Late Paleoindian Sentinel Gap site (45KT1362) and the resulting definition of one of the most complete and informative Late Pleistocene-early Holocene stratigraphic sequences in this region. Stratigraphic Profile 1 illustrates the potential of “accidental” finds and their ability to contribute important new information on landscape development at the Pleistocene-Holocene Boundary.

[22] Aboriginal Grinding Grounds, Stone Tools and Other Archaeological Evidence for Fiber Processing in Australia

There is abundant contemporary and ethnographic evidence for Aboriginal processing of fibers to make string, baskets, nets and cordage. Direct archaeological evidence of fiber processing is sparse. Recent studies suggest a range of microscopic techniques for assessing the function of utilized tool edges and grinding surfaces that are likely to be linked with the acquisition of fibers for craft objects. We present case studies that suggest processing of particular plant taxa, including spinifex grasses, in the past.

[137] A Chemical Comparison of Plaster Surfaces from Actuncan, Belize

This poster presents the results of the chemical residue analysis of four plaster surfaces from two buildings at Actuncan Belize. These surfaces represent two overlaying floors from each building providing an ideal opportunity to compare activity patterning between distinct spaces as well as over time. Recent advances in geoarchaeological research on pedogenesis in cultural settings have demonstrated that soil science has powerful analytical potential for archaeological reconstructions of human activities and land use practices. By analyzing the chemical residues of different activities in anthrosols (soils that have been modified by human activity), activity patterns can be studied in primary contexts even when little or no visible material evidence persists. Additionally, due to its high surface tension from small pore sizes, lime-based (calcium carbonate) plastered surfaces trap and preserve a variety of chemical compounds in a similar manner as soil, and can thus be examined using the same geoarchaeological methods.

Aleut Travel Paths in the Waters of the Rat Islands, Western Aleutians, Alaska

The prehistoric Aleut cultural landscape included terrestrial space and sea space. Aleut kayaking and navigation skills are legendary and Russian era ethnohistories tell us that Aleut men spent as much time on the sea as on land. In fact, all Aleuts traversed their landscape on sea pathways as often on terrestrial trails. Raw material acquisition, trade, and social negotiations all would have been subject to a seafarer’s ability to navigate the tides and currents. The territory of an Aleut lineage may have included non-terrestrial spaces such as coastal, inland, and marine sea regions and may have encompassed non-adjointing terrestrial spaces on one or more islands. Rather than terrestrial proximity, settlements may have been placed for ease or safety of movement in the complex currents caused by deep sea passes between the Pacific Ocean and the Bering Sea. The shortest distance between two places may not have been a straight line. Using geospatial approaches, potential travel paths of more or less difficulty are identified in the waters of the Rat Islands, Alaska. These will be incorporated into forthcoming research about Rat Islands Aleut relationships with their environment and each other.

Chavin-Peru: Combined 3D Technologies for Documenting and Visualizing a UNESCO World Heritage Site for World’s First Chavin Exhibition in the Museum Rietberg Zurich, Switzerland

In 2012, the Museum Rietberg Zurich opened the first major exhibition about Chavin, a temple complex in Peru, in collaboration with researchers from Stanford University. The exhibition aimed to promote early Andean cultural history in Europe, and to support local site improvements in Chavín. Key to these goals was the 3D documentation of Chavin architecture and sculptures. The large-scale 3D documentation of Chavin was realized in 2012 by ArcTron 3D, commissioned by the Museum Rietberg. High-resolution structured light scanning was combined with terrestrial laser scanning and photogrammetry. Aside from ground-based procedures, different airborne technologies were deployed. The result is a full record of the temple complex with high accuracy. Single objects like the Tello Obelisk or the Lanzón cult image were even documented with sub-millimeter accuracies. The virtual core of the 3D documentation is its management and analysis in ArcTron’s 3D GIS system aSPECT3D. Apart from sophisticated interfaces for different scanning technologies, the software offers a PostgreSQL database for structuring and managing large amounts of data. Complementing the model presentation in the exhibition, the 3D documentation forms the basis for scientific analysis and planning conservative interventions.

Ceramic Tools and Other Worked Sherds from the Harris Site, NM

Numerous ceramics are recovered from archaeological excavations in the Southwest, and those classified as decorated and redware are thoroughly studied for their contribution to stylistic differences and as references for dating sites. Ceramics classified as tools and worked sherds have often not received the same amount of attention and have been limited in the depth to which they are discussed in site reports. The ceramic assemblage discussed in this poster was recovered during the excavation of 20 pithouses and other features at the Harris Site in Mimbres, New Mexico during the 2008-2013 field seasons. The majority of the assemblage is represented by complete and preform spindle whorls of various sizes. In addition to the spindle whorls, the worked ceramics were analyzed to interpret their prehistoric potential use as jar covers, scoops, scrapers, figurines, gaming pieces, and traded items. This poster will also discuss the distribution of the worked sherds across the site and the contexts within the pithouses in which they were recovered to examine possible differences between households at the site.

Situational Frames of 17th Century New Mexico: Examining the Built Environment of Spanish Households

Archaeological research of identity often focuses on material culture, but the built environment within which identity is enacted and how changes in a setting can influence the ability of a group to mimic an ideal identity are also relevant. The situational frame is an architectural concept that predicts the built environment and changes in that environment will lead to variations in the activities conducted there. It implies that a physical setting has certain relational expectations and links patterns of human social interactions to a particular built environment, implying that patterns are ingrained in a situational spatial dialect. Therefore, new social settings can develop a unique built environment, and thus behaviors within it as well. In practice, 17th century New Mexican Spanish settlements can be divided into at least four separate situational frames, or categories, based on size and likely purpose. These include the initial settlement at Yunque, the concentrated government center at Santa Fe, medium size households
(estancia/haciendas), and small settlements (villas). This presentation discusses these four categories and how they represent variations in the situational frames of 17th c. New Mexican secular households, as well as possible variations in institutional and social constraints tied to identity.

Experimental Chicha Brewing: Implications for Interpreting Skeletal $\delta^{18}O$ Values in the Andes

Increasingly, $\delta^{18}O$ has become part of the standard battery of stable light isotope values measured in samples of human skeletal and dental remains. Because the $\delta^{18}O$ value of water is affected by evaporation and condensation, meteoric water values increase with increasing temperature, as well as with decreasing altitude, latitude, and distance from the coast, thus water carries a signature of its spatial and temporal source. When imbibed, the oxygen is incorporated into human bones and teeth, which suggests that $\delta^{18}O$ values of these tissues have the potential to provide us with a record of where a person was raised and if that person migrated in the years before her death. However, boiling and open storage also increase evaporation, and these sources of heavy oxygen enrichment must be considered when interpreting human $\delta^{18}O$ values. This may be especially important in the context of the Andes where canals, pukios, and chicha were common sources of water. In this study we experimentally produced chicha de mafz in the lab, as well as sampled the brew of a Moche valley chichera to begin to estimate the magnitude of heavy oxygen enrichment that may have resulted from chicha consumption.

Gahr, D. (Southern Illinois University at Carbondale)

Emancipating Pacific Northwest Archaeobotany from Ethnography while Benefiting from Its Largesse

The agenda of this symposium is to encourage archaeologists to move beyond uncritical reliance on the wealth of our regional ethnographic record in order to build more robust explanatory models and enriched theoretical frameworks. Archaeobotanical research is one of the areas of Pacific Northwest archaeology most impacted by and dependent upon ethnographies and contemporary ethnobotanical research to interpret results. Despite being uniquely poised to study significant questions regarding long term dynamics in society and ecology, this facile reliance on ethnobotanical data has hampered archaeobotanists’ contributions to this research. The growing archaeobotanical record from the Lower Columbia River region reveals increasing incongruities between evidence from archaeological plant remains and the data regarding plant use from the ethnographic and historic records. The challenge set by this symposium led me to re-enter the texts of the oral traditions, ethnographies, and historical documents. I used qualitative research methods to build a contextually, more nuanced, interpretive framework that integrates the archaeobotanical data. Critical points I consider in this paper are the impacts of the regional demographic devastation and colonial contacts on labor organization, including gender roles, dissemination of cultural knowledge, critical resource procurement and processing, and concurrent ecological changes.

The 2013 Field Season of the Projekti Arkeologjikë i Shkodrës (PASH), Northern Albania

The Projekti Arkeologjikë i Shkodrës (PASH), a regional archaeological survey focused on the hinterlands of the northern Albanian city of Shkodër, conducted a fourth season of fieldwork May-June 2013. Survey was extended into new territories, geoarchaeological work was expanded, and a badly damaged burial mound was subjected to geophysical analysis and excavation. Results point to a vibrant, well-populated prehistoric landscape, dominated by large hill forts. Programs of radiocarbon dating and strontium isotope analysis are helping to define the timing, nature, and further development of this landscape beginning in the Bronze Age and through the Iron Age.

Digital Archaeology at Las Cuevas: Comparison of Laser Scanning and Dense Stereo Matching
Techniques for 3D Intra-site Documentation. In the last decades the use of 3D technologies for the documentation and reconstruction of cultural heritage has changed the way to approach the archaeological survey. 3D technologies give the opportunity to digitally preserve the information collected on site through time. In this way archaeology can be revisited over the long-term and, thanks to the following of new discoveries, analyzed by multiple experts and subjected to new analytical techniques. The 3D documentation of the archaeological site of Las Cuevas represented a unique opportunity to test and compare 3D laser scanners and photogrammetric methods in extreme and diverse environmental conditions. This paper presents the results of the 2011 and 2012 fieldwork campaign. Laser scanning and dense stereo matching techniques were used for the 3D data acquisition of three different areas of the site, characterized by diverse environmental conditions and light exposures (cave’s entrance chamber; temple and ballcourt). Quantitative comparisons were conducted between the 3D models coming from the different techniques showing how technologies can be integrated for the optimal recording of the excavation process. The research presented in this paper helps define best 3D practices for the documentation, analysis and interpretation of archaeological sites.

[95] Traditional Cultural Property Study at Camp Bowie: A Comanche Perspective
Camp Bowie, near the headwaters of the Colorado River in Brownwood County, Texas, is surrounded by what the Spanish referred to as “Comanchería,” or Comanche Country. SWCA conducted a Traditional Cultural Properties survey of Camp Bowie on behalf of the Texas Army National Guard, Adjutant General’s Department/Texas Military Forces, in compliance with Sections 106 and 110 of the National Historic Preservation Act, with the objective of managing and preserving TCP resources, while upholding its training mission at Camp Bowie. The Comanche Nation’s Tribal Historic Preservation Officer and five members of the Elder Council participated in two phases of fieldwork in 2013 and identified six TCP locales. Additionally, historic Comanche components were identified for about 40 previously recorded sites. The methodology developed for the Comanche fieldwork and the results of this study are the focus of the presentation.

Galke, Laura (George Washington Foundation)
[233] Mother Washington: Complicating a Significant Narrative Performer
In existing biographies of George Washington’s, accounts about his mother’s role in his life have rarely been neutral. These stories form broad patterns that reflect popular ideologies of motherhood, women, masculinity, and the nature of success. Archaeological investigations at George Washington’s boyhood home in Fredericksburg, Virginia (c. 1738-1774) complicate these stories. The resilience of popular narratives in the face of contrary historical and material culture evidence is the focus of this presentation.

[170] Early Chili Peppers Evidence at the Site of Chiapa de Corzo, Chiapas, Mexico
Peppers or fruits of Capsicum species have rarely been identified in the paleoethnobotanical record in either Meso- or South America. We report here confirmation of Capsicum sp. residues from pottery samples excavated at Chiapa de Corzo in southern Mexico dated from Middle to Late Preclassic periods (400 B.C.E. to 300 C.E.). Residues from 13 different pottery types were collected and extracted using standard techniques. Presence of Capsicum was confirmed by ultra-performance liquid chromatography (UPLC)/MS-MS Analysis in five pottery types. Results of the chemical extractions provide conclusive evidence for Capsicum use at Chiapas de Corzo during a 700 year period (400 B.C.E. – 300 C.E.). Presence of Capsicum in different types of culinary-associated pottery raises questions about how chili pepper was used during this early time period. As each vessel that tested positive for Capsicum had a
culinary use we suggest here the possibility that chili residues from the Chiapas de Corzo pottery samples reflect either paste or beverage preparations for religious, festival, or every day culinary use. Alternatively, some vessels that tested positive could have merely been used to store peppers.

[171] The Archaeology of Indigo Dyeing in Burkina Faso, West Africa
Indigo dyeing is a complex process that has been practiced in West Africa for at least 1000 years. Indigo cloth production is well-documented in historic and ethnographic accounts, where textiles are frequently described as valued items used in a variety of secular and religious contexts. While the degree of specialization and intensity of production varies greatly throughout the region (as do gendered associations of various components of the production process), in general indigo cloth is well-established as having been a major trade commodity in regional systems. Archaeologically, the majority of research to date has focused on the rare finds of preserved textiles and production of the cloth itself. This poster explores the archaeological signatures of indigo dyeing in southeastern Burkina Faso, including the infrastructure (plastered dye pits), material culture (pots), and waste products (ash) associated with the indigo dyeing process, and presents results from regional survey south of the Gobnangou escarpment, an area associated with the pre-colonial Gulmance kingdom. The survey identified specialized production areas indicating intensive manufacture of indigo cloth in the late second millennium CE. These remains provide an important line of evidence to contextualize ethno-historical accounts of the role of local polities in long distance exchange.

Gallant, Thomas (University of California, San Diego)

[127] An Historical Archaeology of Everyday Life on a Greek Island: Andros, 16th-19th Centuries CE
This paper contributes to the historical archaeology of everyday life by presenting the preliminary results of the first two fieldwork sessions of KASHAP [the Kefallenia and Andros Social History and Archaeology Project]. The project brings together historians, archaeologists, natural scientists, big data graphics specialists and others to track the human and environmental histories of the islands. It explores the social and economic systems as well as the material culture of these two island populations. One of the main themes of the project is to explore how being integrated as peripheries into major premodern empires, in this case the Venetian Empire and the Ottoman Empire, shaped the contours of everyday life and how the transition from empire to nation-state impacted society and economy. The first phase of the project has focused on the northern region of the island of Andros, concentrating on the collection of environmental data, the mapping of agricultural field systems, plotting the road network, analyses of terrace walls, the excavation of two farmhouses that were occupied from the late 17th to the late 19th centuries, and the collection of archival materials (land leases, sales agreements, dowry contracts, and wills, for example).

Gallivan, Martin (William & Mary)
[159] Place-Making in the Algonquian Chesapeake
A 17th century origin story from the Algonquian Chesapeake describes the benevolent god Ahone and sacred winds blowing across a world without people. After giants killed and sacrificed the first deer in this world, Ahone released the people from his bag to place them in different areas. Formerly a landscape of water and fish, the Chesapeake became a circular disc centered on the Powhatan. This account may be read as a narrative of place-making, the process of creating a meaningful place-world through stories of “what happened here”. Taking this colonial-era story as a point of departure, this paper outlines a deep history of place-making in the Algonquian Chesapeake. The precolonial arrival of Algonquian speakers in the region—estuarine-oriented fishing communities—coincided with the creation of places of interaction with deer-hunting foragers long-resident in the area. During the following centuries Native communities established riverine settlements, centering some on circular enclosures surrounding ritualized spaces. Even after English colonists seized their lands, Native groups returned to these locations to sacrifice animals and to inter objects of social importance. Such pilgrimages and performances contradict a narrative of abandonment and disappearance, highlighting the enduring power of place in the Algonquian Chesapeake.

[195] Stucco Façades in the Puuc Region: Interpretation of a Dismantled Stucco Façade Found in a Deposit at Kiúc, Yucatan
In the Puuc site of Kiúc, a destroyed modeled stucco façade was identified in 2009. This talk centers on the research that was conducted on this deposit and the materials found within it. The research focused on the stucco remains and the possible purposefully deposited nature for its interpretation. The importance of this deposit lies in the sociopolitical implications of the destruction of the building and its decorated façade; linking this event with the spatial, social, and political history of Kiúc. The research was mainly based on developing a typology that allowed for a morphological analysis of the stucco fragments. This was complemented with the information of an analysis of the associated ceramics and lithic in order to contextualize the stucco and the deposit in its entirety.

Gamble, Lynn (University of California, Santa Barbara)
[85] Social and Ritual Transformations in Coastal Hunter/Gatherer Communities in the Santa Barbara Channel Region
Exchange and resource variability has traditionally played a prominent role in discussions of island/coastal mainland interactions and the emergence of sociopolitical complexity in the Santa Barbara Channel area, a region with no major population replacements for at least the last 10,000 years. Although these economic explanations are significant, ritual and political transformations are also integral to the emergence of permanent inequality. Sacred and symbolic coastal landscapes, ritual performances and accompanying paraphernalia, gift giving, shifting alliances and entanglements, and political integration contributed to the complex hunter-gatherer Chumash society that was documented at the time of European contact in the region. I examine these variables from the lens of historical contingency using multiple scales of analysis to better understand emergent polities in southern California.

Gamboa Velasquez, Jorge (Proyecto Pañamarca y Universidad Nacional Santiago Antunez de Mayolo)
[27] The Enclosed Public Space: Moche Plazas as Places of Social Encounter
The complexities of Moche sociopolitical organization have been recently re-evaluated through theoretical approaches and historical reconstructions. Nevertheless, the spatial, functional, and symbolic characteristics of Moche ceremonial plazas have not been subjected to similar scrutiny. Our knowledge of the materiality of Moche plazas is limited by the small number of extensive excavations in this type of architectural space. However, relevant data is available on the design and functionality of plazas from Huacas de Moche, El Brujo, Galindo, and Dos Cabezas among other sites. The Moche ceremonial plazas appear as extensive walled spaces, decorated with murals that emphasized representations of gods, warfare, and sacrifice, and used for massive audiences and private events of political negotiation, authority and consecration. A symposium dedicated to examining our current knowledge on Andean
plazas becomes the appropriate means to assess both how our understanding of Moche plazas has advanced and to orient future study of these major public buildings.

Gandy, Jennifer (Gault School of Archaeological Research and Texas State University) [318]  *Defining Older-than-Clovis at the Gault Site through the Statistical Analysis of the Lithic Debitage*

In 2002 and 2007, testing at the Gault Site in Central Texas revealed intact archaeological deposits below Clovis. Since then, ongoing investigations at Area 15 have focused on the earliest intact deposits, particularly the Clovis and Older-than-Clovis (OTC) components. Twelve 1-m-x-1-m units were excavated below Clovis as 5 cm levels. The OTC deposits are now known to be approximately 80 cm thick, and a number of cultural materials have been recovered from these deposits, the majority of which was lithic debitage. This analysis was conducted to define the OTC debitage and to compare and contrast it with that of Clovis. Since knapping behaviors can be inferred primarily from the striking platforms of flakes, the main criterion for choosing flakes for analysis was the presence of identifiable platforms or platform remnants. A 100 percent sample of flakes meeting this criterion was chosen from six of the twelve OTC units, totaling 2,395 flakes. Statistical analyses of flake and platform attributes were performed as a means of characterizing these flakes and the technology or technologies they may represent.

Gandy, Jennifer [318] see Velchoff, Nancy

Garber, James (Texas State University) and Kathryn Brown [31]  *Preclassic Architecture and Ritual at the Site of Blackman Eddy, Belize*

Our understanding of the early Maya has increased dramatically over the past forty years. In many respects, the discoveries at Cuello opened the door for new questions about the origins of Maya civilization, pushing back the established time-line for the earliest settled villages. Following on the heels of Cuello, new discoveries in the Belize River Valley added significantly to our knowledge of this important and dynamic period. Investigations at the site of Blackman Eddy revealed a developmental sequence of Middle Preclassic public architecture and associated ritual deposits. Detailed analysis of materials from these ritual deposits suggests that communal feasting was an important component of early ritual behavior. The Preclassic architectural sequence culminated in the pyramidal form of architecture decorated with deity masks. In this paper we revisit the data collected at Blackman Eddy and present our current interpretations in light of new Preclassic discoveries in the Maya lowlands.

Garcea, Elena (University of Cassino and southern Latium) [198]  *The Southern Periphery of Egypt in the Predynastic Period: Nubia in the 5th and 4th Millennium B.C.*

From an economic viewpoint, ancient Nubia was the southern periphery for Egypt. Their relationship was not strictly reciprocal as Egypt was not the northern periphery for Nubia; and Egypt depended more on Nubia than Nubia dependent on Egypt. The higher independence of Nubia could be related to the fact that sedentary settlements were not a successful form of adaptation in the Nubian landscape. Conversely, mobility allowed Nubian populations to avoid the needs for a greater dependence on large quantities of resources, human labor, and political relations. Nomadism was also more successful because of the different physical landscapes in the Egyptian Nile valley and in the Nubian valley: while the former features a vast alluvial plain, the latter is intersected by a series of rocky outcrops, which form cataracts affecting the extent of flooding and impeding navigability. Therefore, two opposite, but complementary, systems were established: agriculture with sedentism in Egypt, and pastoralism with nomadism in Nubia. Consequently, as the Egyptian dynastic kingdom developed, Nubia remained a peripheral, but never ‘marginal’ political landscape. In fact, it was able to sustain alternative pathways to power, which reached its peak with the rise of the Kerma civilization ca. 2500 B.C.

García-Des Lauriers, Claudia (California State Polytechnic University, Pomona)
Beyond the Strategic: Cerro Bernal and Los Horcones as a Sacred Landscape

Since 2005, the Proyecto Arqueologico Los Horcones (PALH) has been investigating the site of Los Horcones located in the municipality of Tonalá, Chiapas, largely looking at its role as an important interaction node in the region during the Early Classic (A.D. 250-650). Archaeological research conducted by earlier scholars and more recently by me has focused on the strategic location of Los Horcones as an important factor for understanding its relations with Teotihuacan, the Maya region, and the Gulf Coast. While conducting research there, local residents shared with me stories of the importance of Cerro Bernal and its natural features as ideologically potent elements of the landscape. I recently went back and interviewed several long-time residents of Cerro Bernal and in this paper I will combine information from these interviews, research on Mesoamerican sacred landscapes, and the archaeology of Los Horcones to present this site and Cerro Bernal as more than just a strategic landscape—it was also a deeply meaningful sacred location.

Garcia-Herbst, Arleen (ECORP Consulting)

Hunter-Gatherer Land Use and Landscape in Late Holocene Southern Patagonia, Argentina

Landscape studies try to explain how specific places or spaces in the natural environment were used or manipulated by humans in an attempt to codify their economic practices, socio-political organization and ideological beliefs. This paper will explore the relationship between the prehistoric and ethnographic native peoples and cold, arid environment of Southern Patagonia and Tierra del Fuego, focusing primarily on the portion of land or areas falling east of the Andean mountain chain, within the country of Argentina, and between Parallel 49 S and 55 degrees South.

García-Moreno, Cristina (Arizona State University/Centro INAH Sonora)

Cultural Interactions in Ónavas Valley, Sonora, México

Recent research in southeastern Sonora, México, particularly in the valley of Onavas, has provided valuable information on cultural practices of the ancient inhabitants of this region. Through the recovered skeletal remains of a burial site we have uncovered the funerary practices of the group occupying the valley between A.D. 943 and 1481. From the presence and characteristics of cranial and dental modifications of some of the skeletons (cultural practices that have not been reported in any other region of the state), we suggest that this population had a greater affinity with populations of Sinaloa and northern Nayarit; however, we have not found other attributes of the cultural traditions of the Mexican west coast. Despite this, we believe that the valley of Onavas is part of the cultural corridor of the West-Northwest/Southwest.

Garcia-Putnam, Alex (East Carolina University Department of Anthropology) and Megan Perry (East Carolina University Department of Anthropology)

An Investigation of the Taphonomic Effects of Animal Scavenging

Numerous environmental and human-induced variables that affect decomposition can cloud accurate estimations of the postmortem interval (PMI). For instance, scavenging animals can remove soft tissue and disarticulate and scatter remains, resulting in faster-than-expected decomposition. This study investigates the impacts of animal scavenging on decomposition rates and estimations of the PMI in eastern North Carolina using pigs (Sus scrofa) (n = 4) as analogs for human remains. Systematic observation over a five-month period documented which scavengers affected the death scenes, the decompositional changes of each subject, and the scattering patterns of the skeletal elements to determine whether or not scatter patterns over time can be predictive of the postmortem interval. One specimen enclosed in a wire cage served as a control. Motion sensing cameras were positioned at the three exposed sites to capture images of scavenging animals. Vultures and canid scavengers produced the most pronounced scattering events. The exposed remains reached full skeletonization and disarticulation by day 8, while the control reached a skeletal state by day 23. Scatter patterns, however, are not strongly predictive of the time since death.

Gardiner, Julie (Oxbow Books), Mark Lynott (National Park Service, Nebraska) and Peter Topping (University of Newcastle upon Tyne)
American Landscapes is a publication project created and funded by Oxbow Books/David Brown Book Company that is designed to present a series of lavishly illustrated volumes exploring the landscape history of the North American continent. Each volume will provide a comprehensive and accessible narrative aimed at the informed reader, presenting an up-to-date review of the latest research from archaeology, anthropology, historical studies and the environmental sciences, which will also provide a guide to the detailed literature. The aim is to produce an expert overview—from a holistic landscape perspective—of the history and changing land-use of particular areas/regions or archaeological/historical themes across a wide timeframe in the United States and Canada. This poster presents the major themes and subject areas we are exploring and highlights future contributions to the series that are not represented in contributing posters to the session in order to demonstrate the range and breadth of the project.

(Dis)ability in California Prehistory: Interpreting Social Roles of Individuals with Disabilities from CA-SCL-38 through Mortuary Context and Stable Isotope Analysis

The Yukisma Mound (CA-SCL-38) in Santa Clara County, California, was a ceremonial and mortuary site used by the ancestral Ohlone from at least 780 until 230 BP. Osteological analysis of the burial population revealed that 24 individuals (10% of the 248 recovered) exhibited evidence of some condition that would have significantly influenced their participation in life activities. These included congenital or developmental defects, traumatic injuries resulting in prolonged infections or compromised limb function, chronic infectious disease, and cranial trauma associated with neurological disorders. This study examines the social roles of these individuals within the community, including status, wealth, and ritual specialization. While associated artifacts provided clues about social adaptations and accommodations, these individuals were ultimately as likely to have evidence of wealth or ritual roles as others in the population. Variation in dietary patterns fell within the range for able-bodied individuals. Mean 513C and 515N values of bone collagen and 513C values of bone apatite for this group were all within 0.10o of the population means. This integrated analysis suggests that individuals with disabilities were well regarded and cared for by the ancestral Ohlone, but that they did not receive special recognition or status because of their conditions.

Food-Way Changes during the Formative Period in Northwestern Colorado

Excavated rock shelters in northwestern Colorado contain extensive data sets that are increasing our understanding of Formative Period (2000-500 B.P.) diets. As a result we are gaining insights into the relationship between cultivated and gathered plant resources in the region. In this paper we will look at the significance of maize, xeric grasses, piñon nuts, and chenopodium in the diet of the Formative groups in the region. We will offer some tentative suggestions about which plants were cultivated and which plants were gathered. This paper provides a brief summary of what we have learned in our excavations over the last ten years and offers a cautious proposal regarding plants that may have been cultivated along with maize in northwestern Colorado during the Formative Period.

[160]  
Household Population Dynamics from the Ground Up: Preliminary Results from a New Agent Based Computer Simulation

The internal demographic structure of Pacific Northwest Precontact households is largely a black box to archaeologists. Demographic reconstruction must rely on growth equations, extrapolation from recovered human remains, and ethnography. A new computer simulation conceived as tool to explore population
dynamics hypotheses is described here. The simulation takes individual agents grouped into households as its basic units. Agents’ life histories move from birth through marriage to having children and ultimately death. These events across generations define a household’s lifecycle from founding to dissolution. Stochastic factors such as fluctuating food production and catastrophes with variable effects are incorporated. Complete records of life events for all agents are produced allowing the reconstruction of individual life histories. Initial results suggest that slight, culturally controlled variables, such as a shift of as little as one year in the age at which female agents start having children, have significant impacts on household lifecycles. Mean age of household members seems to gravitate toward 20-22 years old, with slight increases associated with rapid population decline. Although the simulation is designed with a specific geographical area and time period in mind, it is flexible enough to allow demographic modeling beyond the Pacific Northwest.

Garduño Ambriz, Mauricio (Instituto Nacional de Antropología e Historia/Centro INAH Nayarit)

San Felipe Aztatán: New Data on Iconography of the Aztatlán Culture (A.D. 850/900-1350 A.D.) of the Northwestern Lowlands of Nayarit

After a long process of institutional delay, in early 2013 it was possible to recover an elaborately decorated polychrome vessel pertaining to the Aztatlán cultural complex (A.D. 850/900-1350) of the northern Mesoamerican coast, whose core area of development took place in the fertile alluvial lowlands of southern Nayarit and southern Sinaloa. The finding of this vessel took place in a fortuitous manner over twenty years ago at a site located within the urban area of San Felipe Aztatán on a level surface atop a platform located at a distance of 130 meters westward from the Loma de la Cruz. This mound is the main ceremonial edifice located within the architectural core of San Felipe Aztatán and is astronomically oriented on an east-west axis and ritually linked with sun worship. The vessel in question is decorated within the pictorial tradition known as “codex style”. Grouped into two main scenes related to upper levels of social status are a total of 24 characters, which covers practically the entire outer surface of the vessel, including its base. Themes to be discussed include the depiction of ritual sacrifice of a person by heart extraction, a decapitated individual, and a cremation burial rite.

Garfin, Timothy (California State University Long Beach) and Hector Neff (CSULB)

Exploring Settlement Patterns in the Littoral Zone of the Soconusco Coast

The goal of this poster is to explore the preliminary results of recent survey work done in the Soconusco Coast region and to combine this with an older corpus of data. The key sources of data come from the NSF funded Proyecto Arqueológico Costa Del Soconusco (PACS) and survey data from Coe and Flannery, Shook, and Love. The key methodological issue is evaluating how older types of survey methods can interact with more technologically sophisticated techniques. Many of the sites were identified deep within the coastal mangrove swamps using LiDAR which presents archaeologists with a set of data options that are much more flexible and rapidly deployable than pedestrian survey. By combining these data sources it should be possible to create a more accurate and dynamic picture of the archaeological landscape in the region and map how site utilization and distribution changed over time.

Exploring Production Sources and Technologies for Hohokam Brown-Paste Decorated Pottery in the Lower Salt River Valley: New Evidence from La Ciudad, Phoenix, Arizona

Throughout the Hohokam Pre-Classic period (A.D. 650 –1150), decorated pottery vessels in the lower Salt River valley almost exclusively consisted of imported Red-on-buff wares from the adjacent middle Gila River valley to the south. For a brief span during the Gila Butte phase (A.D. 750–900), however, low-level production of brown-paste decorated pottery in the lower Salt valley supplemented Red-on-buff imports from middle Gila region, which accounted for about 15 to 40 percent of decorated sherds from sites along the lower Salt River. The brown-paste, red-painted pottery closely mimicked the decorative
design and vessel forms of the middle Gila Red-on-buff wares, but inspection of paste and surface attributes indicates crucial differences in production technologies and raw materials. Based on an analysis of ceramics from recent excavations at the site of La Ciudad in downtown Phoenix, I consider multiple lines of evidence to explore potential production sources in the lower Salt valley and the technological choices employed by manufacturers of the brown-paste pottery. I conclude by proposing several hypotheses for the development of a local decorated pottery tradition during the Gila Butte phase.

Garrett, Zenobie (New York University)

Transitional sites in the Post-Roman World: Sites Survey Analysis of the Roman and Early Medieval Periods in the Vézère Valley (Dordogne, France)

The end of the Roman Empire was an unprecedented moment of cultural contact and change. Although a much cited example of classic societal collapse and regeneration models, research over the past 20 years suggests a more complicated picture of continuity and change during the early medieval period in Europe. In France, the subsequent rise of the Frankish Kingdom during this time represents the earliest coalescence of political control in post-Roman Europe. While archaeologists have long recognized the importance of the Frankish kingdom for exploring questions of continuity and cultural change, studies of post-Roman France have focused exclusively on the northern and eastern regions. Thus, the as underexplored region of Aquitaine in the southwest is a crucial missing piece in the puzzle of early medieval Europe. This paper presents the preliminary results of site survey in the Vézère river valley, in the Dordogne department of southwestern France. In addition to introducing the under-explored medieval archaeological potential of this region, the analysis presents methodological strategies to combine multiple, disparate data sets and analyses this key transformation in societal organization.

Depositional Integrity of Area 15 at the Gault Site - Utility of Geomagnetic Analysis and Diagnostic Notching Flakes

This report demonstrates the utility of diagnostic Andice notching flakes and geomagnetic analysis of one of the several burned rock features (F18-10) at the Gault site, to provide depositional integrity values. At approximately 8,000 years old, this hearth is potentially significant for understanding the early part of the long time interval known as the Archaic (from roughly 9,000 to 1,000 BP). In addition, its placement directly above the Paleoindian materials makes its proper interpretation of utmost importance. Demonstrating that the feature is intact, or virtually unMOVED since its construction, supports the notion that materials underneath are similarly intact.

“We may have to call someone”: 3D Technologies in the Context of Lowland Maya Field Archaeology

This paper examines the pros and cons of integrating 3D technologies into a field project in the Maya lowlands. Since 2006, the Proyecto Arqueológico El Zotz in northern Guatemala has implemented a variety of digital 3D methods over the course of eight seasons of fieldwork. From close range photogrammetry and laser scanning for monument documentation to the use of software such as Google SketchUp and Maya for architectural visualization, 3D technologies have been a part of the day-to-day field operations on site. These applications have had mixed results when compared to more traditional archaeological field methods. This talk will highlight the experiences PAEZ members have had as jungle archaeology continues into the 21st century. It highlights both successes and failures while making recommendations for the future.

Garrison, Ervan, Timothy Anderson (University of Grenoble) and Kent Schneider (University of Georgia)

Architectural Inference from Ground Penetrating Radar (GPR) Surveys of an Unexcavated Roman Country Villa, Châtillon-La Vuarda, Switzerland

In 2004, a ground radar study based on earlier surface collections and aerial photos confirmed the presence of a Roman-style villa near the modern Swiss village of Châtillon-La Vuarda. Our subsequent re-analysis of the radar data in 2012-13 clearly indicated architectural details consistent with those of a pars urbana or domiciliary portion of a villa complex. This conjecture is based on a careful re-analysis of the radar data that resolved key architectural details not seen in the original analyses done shortly after
the field surveys in 2004. In the 1990s, Denis Ramseyer conducted mechanical trenching northwest of the villa proper, where geophysical features had appeared on an earlier resistivity survey’s results. A second series of trial trenches were carried out, systematically, by co-author Anderson in the same parcel as the first set of trenches. Anderson’s study confirmed that the building does not stretch to that parcel. Combining the geophysical, preliminary excavation data and archaeological information obtained from recent, contemporaneous excavations of villa sites in the Germania Superior of the Swiss Plateau, allows us to interpret these data with greater confidence and support our conjectures regarding spatial and architectural details of villa complex.

Gasco, Janine (CSU-Dominguez Hills) [284] Ecology, Economy, and Cacao Cultivation in Soconusco, Chiapas, Mexico

For almost four millennia, cacao has been cultivated in the Soconusco region of Chiapas, Mexico. In this paper I explore the relationships among local ecological systems, economic change, and the cultivation of cacao in Soconusco from late Prehispanic times to the present. As a highly desired and relatively scarce commodity, cacao has long been an important export crop produced in Soconusco’s tropical forests, yet ecological features, economic forces, and cultivation practices have changed considerably over time. Here I compare the nature of these changes for the Late Postclassic, Colonial, Post-colonial, and contemporary periods to better understand the complex interplay among ecological and economic factors and local cultivation strategies. I also consider the broader implications of these changes for local cacao farmers, how they are manifested in material culture and the archaeological record, and likely trends for the future.

Gastaldi, Marcos [19] see Bertolino, Silvana Raquel Alina

Gates-Foster, Jennifer (University of North Carolina at Chapel Hill) [194] Abundance and Innovation in the Production of Roman Tablewares

The widespread distribution of certain Roman tablewares from Italy, the Gallic region, and North Africa is a well-documented aspect of the economy of the Roman era. These glossy red fine wares, known as terra sigillata, can be found in abundant quantities throughout the empire, second only in quantity to the amphora with which they were often paired in transport. Some of these products were distributed practically empire-wide, while others had a more limited distribution alongside locally-produced fine wares that were cheaper and in many cases imitated popular imported sigillata forms. The visual experience of large quantities of pottery of this type both in households and in the environment, where discarded fragments of sigillatta formed a large component of household debris, undoubtedly shaped ideas about the desirability of particular styles and shapes, as well as the values attached to these objects. This paper will focus on the role of abundance in the consumption of Roman sigillatas, as well as the way that changes in vessel form and decoration may be understood as a response to quantity as a visual and empirical experience. Particular attention will be paid to the pace of stylistic change in production centers in Europe and North Africa.

Gatto, Maria (The Aswan-Kom Ombo Archaeological Project; Yale University) and Kimball Banks (Combined Prehistoric Expedition Foundation and the) [88] Archaeology in Egypt during The Arab Spring

The Egyptian Revolution in 2011 has affected how archaeology is now conducted in Egypt. The revolution has also affected how Egyptians themselves feel about their country’s heritage and the archaeologists exploring that heritage. Although pharaonic archaeology has suffered the most, prehistoric archaeology has also been impacted. With the overthrow of President Morsi, archaeology and archaeological sites also have become a political issue. In this regard, what is happening in Egypt is emblematic of issues facing other countries that have experienced the Arab Spring. To a large extent, the politicization and degradation of archaeology can be viewed as reflecting the Islamist worldview: “There is no god but God“.
Gaude', Dana (Louisiana State University) and Heather McKillop (Louisiana State University) [233]

3D Imaging and 3D Printing of Coffin Handles from St. Thomas Anglican Churchyard, Belleville, Canada

The use of 3D imaging and printing in Archaeology is a burgeoning field that provides researchers and the public an opportunity to preserve and engage with the past. Nineteenth century Victorian attitudes towards death and burial are shown in motifs on gravestones, funeral art, and garden cemeteries. Decorated coffin handles from St. Thomas Anglican Churchyard show similar motifs, as well as the change from using furniture handles to coffin handles with the rise of the funeral industry. We carried out 3D imaging of coffin handles for archival and research purposes, with 3D printing for display and educational purposes. Scans were conducted using the NextEngine 3D Scanner and edited with ScanStudio and Rhinoceros software in the LSU Digital Imagining and Visualizations in Archaeology (DIVA) lab.

Fortress of Power and Resilience: Krobo Hill, Ghana

Anthropologists and historians have over decades studied political and social transformation among the Krobo of southeastern Ghana during and after the colonial period. Despite this, the fundamental issues have not been thoroughly addressed: the chronology of Krobo culture history is unknown, the organization and use of settlement, and the interaction between the inhabitants and their unique environment are yet to be well-understood. Also, Krobo material culture, especially the archaeological signatures regarding anti-colonial identity formation, has also not been examined. This is due, in part, to the fact that Klouem, the Krobo ancestral settlements on the Krobo Hill, has never been examined archaeologically. Our ongoing archaeological survey and excavation at the site has produced new data and material culture that promises to improve our knowledge of Krobo power structures, social relations, and social identity. The presentation will explore production, exchange and consumption of prestige goods; the rites of passage before and during European settlement and activities in the region. We will highlight how the Krobo tamed the environment, using terracing, sophisticated water management strategies and religious rituals to create and sustain a unique identity amid increasing European influence between ca.1600 and 1900.

Archaeology Should Be an Introduction

As an introduction of sorts, this talk’s intent is twofold. My exordium provides a brief overview of the session’s inception, concerns, and aims. I also use this forum to deliberate about pedagogical practice in introductory archaeology courses. Few undergraduates who enter into these courses will become professional anthropologists. Of late, news media’s characterization of archaeology and anthropology as two of the most useless undergraduate majors may inform this decision. Unemployment rates and earnings of recent university graduates are cited as evidence. This talk, however, is not a defense of the
discipline. Rather, my concern is assessing how students see lessons about the past as connected to the contemporary sociopolitical world in which they live. What do students take from introductory courses as they pursue professions not in anthropology, but are ever more concerned with administration and management? Does a window into the distant past offer an escape from a dystopic present? Or, do introductory courses provide a springboard for students to re- imaginine their futures—to explore other, more sustainable ways to be human? To begin formulating answers to these queries, I assess the content of syllabi for introductory courses, as well as students’ qualitative comments on teaching evaluations and surveys.

Gelliot, Eric (CEMCA)

Archaeological Sites and Cultural Dynamics in the Area of Lempira, Honduras

In 2011 and 2012 in Honduras, the collaboration project Lempira allowed us to complete the archaeological map of the south of the area of the same name, near the Salvadorian border. We focused on two research axes: the settlement of indigenous sites during the Contact Period and the study of local rock art traditions. Concerning the Contact Period, we conducted a survey of the hill sites of Periol de Cerquin, El Higuate and Cerro Coyocutena, which are linked to the 1537 indigenous rebellion against the conquistadors. For rock art, the sites of the Cueva Pintada de San Antonio Montaria and the Cueva del Duende Susuma could be recorded, and the Cueva Pintada de San Francisco, whose rich polychrome paintings show clear Mexican influences, could be studied. Samples of pigments have been analyzed by the French Research Laboratory of Historical Monuments (Paris). Numerous data throw a new light on the comparative approach of the sites and highlight the rich cultural dynamics of indigenous groups who inhabited this mountainous region of southeastern Mesoamerica. This project was supervised by the French Centre for Mexican and Central American Studies (CEMCA) and the Honduran Institute of Anthropology and History (IHAH).

Struggles for Power: Identifying Political Change between Large and Periphery Sites in the Eastern Petén

Whether used for oppression, rebellion, or social solidarity, religious and political ideologies inevitably change over time. Although considerable research has been conducted on the various functions of religion, a systematic approach is needed to examine which aspects of the identifiable ideological social structure change as a response to each of the aforementioned goals. The political decline of La Milpa during the Terminal Classic period may have inspired smaller local sites to rebel and achieve political autonomy. This paper proposes a preliminary methodology that allows for a relatively quantitative analysis of religious and ritual change during political decline. This methodology compares the architecture, monumentality, political-religious markers, burials, and artifacts of Dos Barbaras with that of La Milpa during the Late to Terminal Classic period of the ancient Maya. By systematically analyzing these variables we can identify shifts in religious and political trends across local sites, examine the correlation between shifting power relations and religious material expression, and identify which variables are altered, highlighted or forgotten within social memory.

George, Richard

Obsidian Provenance, Use, and Interaction at CA-ORA-64 during the Early and Middle Holocene

Environmental and cultural transitions in southern California during the Early and Middle Holocene resulted in population movements, long distance interaction, and the development of extensive exchange networks connecting the Channel Islands and the northwestern Great Basin. This paper integrates two analytical chemical techniques to examine and define patterns in obsidian procurement and use at CA-ORA-64, a multicomponent coastal shell midden with an occupation beginning in the Early Holocene and Middle Holocene. The recovery of 761 obsidian artifacts included a variety of exhausted and broken tools and maintenance debitage. The results of the analysis emphasize the importance of Laser Ablation-Time of Flight-Inductively Coupled Plasma-Mass (LA-TOF-ICP-MS) and X-ray fluorescence (XRF) analyses to identify spatial and temporal patterns in interregional interaction and exchange networks of coastal hunter-gatherers in southern California.

[67] The Graveyards of Adam, Oman

This paper will present the new results of the excavations and surveys at Adam, Central Oman. The funerary landscape of the Early Bronze Age (3rd millennium B.C.) is characterized by collective burials in tower-tombs located on the crests and then large collective multi-compartment graves. From the beginning of the Middle Bronze Age (2nd millennium B.C.), a complete change is observed: the Wadi Suq graveyards show an important concentration of single burials in new forms of tombs (cists and cairns), all located on the plain. Taking the example of the graveyards of Adam, we will compare these two practices in order to understand the evolution, continuity, and change of settlement patterns, material culture and society in the "longue durée."

Gero, Joan (American University)

[27] Yutopian's Plaza

The presence of formally prepared spaces to stage aggregational events is familiar from many parts and time periods of the central Andes. In fact, open plazas are essential central features of the earliest monumental constructions in the central Andes. In the Argentinean Andes, however, ceremonial plazas rarely occur at Early Formative sites, represented only by incongruously monumental features such as carved stone “menhirs” or circularly-arranged earthen mounds around a circular open area. The few examples of “plazas” in Northwest Argentina are not directly associated with residential clusters. Excavations at the Early Formative site of Yutopian revealed a “plaza” without ceremonial features. Set apart from the living areas and positioned dramatically at the extreme northern end of the ridgetop site was a unique non-residential area, flat and circular and defined by a perimeter of upright, loosely spaced and partially dressed stones. Are such discrete “plazas” present at other Early Formative sites, and what role/s might such a plaza have played at Yutopian?

Gerstenblith, Patty

[273] Prohibiting Trafficking in Cultural Objects from Areas of Armed Conflict and Occupied Territory: International Legal Instruments and Customary Law

The First and Second Protocols to the 1954 Hague Convention on the Protection of Cultural Property during Armed Conflict prohibit the illegal removal of cultural objects from areas of armed conflict and occupation. Yet the number of nations that have ratified one or both of these instruments is relatively small and many major market nations, such as the United States and the United Kingdom, are among those that have failed to do so. However, based on the precedent of the U.N. Security Council Resolution adopted in May 2003 prohibiting international trade in cultural objects illegally removed from Iraq, which resulted in the widespread adoption of measures by many of the market nations to prohibit such trade, and on other aspects of international law, as well as customary state practice, this paper will argue that customary international law now prohibits the international trafficking in such objects. With the goal of preserving archaeological sites as well as other cultural monuments and repositories by reducing the marketability of artifacts removed under such circumstances, this approach would have universal applicability and would be relevant in situations of emergency conditions which preclude the implementation of other mechanisms that have similar goals.

Geurds, Alexander (Leiden University - University of Colorado Boulder) and Vlaskamp Roosmarie (Leiden University)

[153] The Cuapa Phase: Notes on the Last Prehispanic Ceramic Period in Central Nicaragua

The ceramic sequence for Central Nicaragua was defined in the late 1980s, and currently still remains the main point of reference for archaeological research in that region. The backbone of this sequence rests on test excavations executed at four sites in the surroundings of the modern town of Juigalpa. Recently, studies in the Pacific region have produced a series of radiocarbon dates associated with the Ometepe phase (A.D. 1350-1550), the results of which are now putting into question the validity of locating some of the most well-known ceramic diagnostic types in this Ometepe phase, instead pointing to a Late Sapoa phase signature (A.D. 1000-1350). Effectively, this has reassigned a substantial proportion of the Ometepe phase diagnostics pottery types to the preceding Sapoa time period, currently leaving the chronological sequence unbalanced for Pacific Nicaragua. A possible source of information as to how this discrepancy is to be understood is neighboring Central Nicaragua and its ceramic sequence. Coeval to the Ometepe phase in that region is the Cuapa phase. This paper summarizes the certainties and uncertainties surrounding the Cuapa phase, and includes propositions how to improve our understanding of the last Prehispanic period in Central Nicaragua.
Ghazal, Royal (University of Chicago)

Finding the Signal in the Noise: Reevaluating Intra-Regional Compositional Variability of Uruk Period Ceramics from the Susiana Plain, Iran

In 2004, Instrumental Neutron Activation Analysis (INAA) was conducted at the University of Missouri Research Reactor (MURR) on Uruk period (ca. 3500-3100 B.C.) pottery sherds from the sites of Chogha Mish, Tepe Sharaefabad, and Abu Fanduweh on the Upper Susiana Plain, Iran (Ghazal et al. 2008). Previous INAA research in the Susiana Plain (Berman 1986, 1987) concluded that clay sources were too homogenous to be analytically useful in reconstructing compositional groups. Later statistical reanalysis of Berman's data (Kouchoukos 1998; Ghazal et al. 2008), however, revealed that more compositional diversity existed than was previously indicated. Subtle but real differences in geochemistry could be seen in all three of our principle sites. Firstly, this paper will present the results of our trace-element analysis. Secondly, we will reexamine preliminary conclusions regarding the organization of ceramic production in the Susiana (c.f. Wright and Johnson's (1975) popular "centralization hypothesis"). Finally, this paper will explore the utility of further INAA research in the Susiana Plain in light of the results from Leah Minc's (forthcoming) multi-regional synthesis of Uruk-related trace-element data.

Giambastiani, Mark

Inferences from the Spatial Distributions and Composition of Rock Art Sites in West-Central Lincoln County, Nevada

An ongoing archaeological inventory of more than 33,000 acres in Nevada, funded by the BLM's Lincoln County Archaeological Initiative (LCAI), has identified and has examined more than 100 rock art sites in three Areas of Environmental Concern (ACECs) – Mt. Irish, Shooting Gallery, and Pahroc Rock Art. Basic data from this effort show clear patterns in site location and content (both rock art and archaeological) that have important implications for site function and local land-use practices that differ from those normally attributed to rock art sites.

Giambastiani, Dayna and Andrea Catacora (ASM Affiliates, Inc.)

A Comparative Study of Incised Stones from Eastern, Central, and Southern Nevada

Incised stone artifacts are fairly common at archaeological sites throughout Eastern, Central, and Southern Nevada; however, the data are not consistently recorded or readily available for analysis. In addition to pieces recently identified at surface sites in the Northern Monitor Range, several incised stone collections and individual artifacts from sites across the state are currently housed in regional and university museum repositories (e.g., Tonopah, Carson City, U.C. Davis). The first goal of this study is to compile a cumulative dataset of incised stones from these disparate sources. Thorough recordation and analyses of these collections will facilitate a comparative study and make the data easily accessible to the archaeological community. The second goal of this study is to assess whether patterns of regional trends in design styles, engraving techniques, and/or patterns in use/reuse can be demonstrated.

Remote Sensing of Vegetation as a Proxy for the Discovery and Delineation of Archaeological Sites

When archaeological remains are not directly identifiable in remotely sensed data, other aspects of the local plant physiology often serve as proxy for their presence. Three principal aspects of the relationships between vegetation and archaeological sites are addressed: first, many archaeological sites contain unique assemblages of vegetation. Secondly, subsurface conditions influence the physiology of plants growing on archaeological sites. Thirdly, the heterogeneity of plant species might be higher on archaeological sites than on non-sites. These phytoarchaeological objectives are addressed through the use of remote sensing data collected from prehistoric sites located along the Gulf of Mexico. Among the findings we note that plants growing over hard substrates such as shell middens have “non-healthy” spectral response curves due to less efficient photosynthetic processes when compared to plants growing over highly organic substrates. Specific segments of the EM are used to characterize the vigor or
stress of plant communities and their relationship to archaeological sites. Elevation data collected from active remote sensing systems assist in the location and prediction of archaeological site location in coastal environments. There exists the possibility that a “vegetation heterogeneity index” can be computed from remote sensing data that would identify areas of high probability for archaeological sites.

[87] TPWD Trail Surveys on Big Bend Ranch – More Questions than Answers
In 2004, the Texas Parks and Wildlife Department (TPWD) initiated an extensive program of multi-use trail development at Big Bend Ranch State Park (BBRSP) in far southwest Texas. As a step towards protecting the cultural resources at BBRSP during the development and subsequent use of these trail corridors, reconnaissance- and survey-level archaeological assessments were conducted during the 2004 through 2010 field seasons. In the course of this project, well over 200 archaeological sites were recorded across roughly 7500 acres of rugged Chihuahuan Desert. Almost 900 cultural artifacts were collected, spanning the Paleo-Indian occupation to the modern ranching and mining period. Where possible, site and artifact analysis was structured to complement existing regional archaeological research frameworks developed for the Trans-Pecos region of Texas. This presentation is an effort to evaluate the results of this project, as well as to discuss some new research opportunities that were inevitably born of this process.

[222] Social Variability during the European Bronze Age: Isotope Results from Cremains and Inhumations from Békés Jégvermi-kert, a Middle Bronze Age Cemetery in Eastern Hungary
Research by the Bronze Age Körös Off-Tell Archaeology (BAKOTA) Project has identified a large cemetery and settlement in eastern Hungary dated to the Middle Bronze Age (2000-1500 B.C.). Data from surface collection, remote sensing, and excavation at the Békés Jégvermi-kert site indicates that the cemetery is very large (at least 3 hectares) and that multiple funerary rituals were practiced, including cremations and inhumations. The Békés Jégvermi-kert site represents the only Middle Bronze Age cemetery in the region and provides an important source of information for understanding regional characteristics of social organization, mobility, and trade during the European Bronze Age. In order to reconstruct social variability at this site, the BAKOTA project has taken a multidisciplinary approach that integrates data from funerary customs, skeletal variability, isotopic patterns, and chemical and petrographic composition of ceramics. This paper presents the isotopic subset of those data. Radiogenic strontium isotope ratios (87Sr/86Sr) from five cremation burials and two inhumation burials (not-burned), as well as archaeological faunal specimens collected from the site will be discussed.

[65] Parsing the Data: The Development and Utilization of ArchaeoSTOR for Ceramic Analysis
Effective data management has increasingly become an important part of archaeological excavations as more and more disparate techniques have become a common part of regular archaeological research. This is apparent at the site Khirbat Hamra Ildan, which was excavated over the course of four different seasons as a part of the Edom Lowlands Regional Archaeology Project. This site offers unique challenges because its excavations occurred with large gaps between seasons, with significant developments in the kinds of data that could be recorded and in the methods used for data collection. Over the course of those seasons, tens-of-thousands of ceramic sherds were excavated and have since been stored at the University of California, San Diego. This material has presented a data management nightmare in sheer physical volume of the information and complications integrating new digital technologies into the data structure. The complexities of managing the increased complexity of our data
in physical and digital forms necessitated a new way of organization. The web application ArchaeoSTOR was developed to meet the challenges for proper curation and the goals of analysis. This paper will demonstrate how ArchaeoSTOR has been used in both the field and the lab to analyze ceramic data.

Giersz, Milosz

[203] Wari Imperial Mausoleum at El Castillo de Huarmey

Between August 2012 and September 2013 the Polish-Peruvian team led by Dr. Milosz Giersz of the University of Warsaw has discovered and excavated an intact burial chamber under an imperial mausoleum at El Castillo de Huarmey site, north coast of Peru. This discovery exceeds in both number and quality any other previous find related to the Wari and Tiahuanaco cultures. 57 female individuals, originally seated and wrapped in textiles, were accompanied with human sacrifices and exceptionally valuable artifacts, as more than 100 ear ornaments, pectorals and necklaces, pendants, tupu-pins, rings, kero cups, rattles, knives, chisels, axes, spearheads, containers, as well as many objects related to weaving, together with the great mosaic of pottery. All offerings stand out for their finish and the materials used, such as gold, silver, copper and its alloys. The discovery of the first ever Wari noblemen's tomb, surprisingly located away from the supposed Wari capital in Ayacucho, is a new topic for discussion of the presence of the southern empire in the Peruvian north coast. This paper shows that this tomb was part of a planned imperial elite mausoleum and that the overlying monumental building served as the physical focus of Wari's ancestor worship.

[228] ARC Smart: Promoting Archaeology through Educational Outreach with Robust Longitudinal Assessment

This paper seeks to analyze the long-term effectiveness of the University of Southern California's ARC Smart, an outreach program designed to educate sixth grade students from the Los Angeles Unified School District about the field of archaeology. In sessions that include artifact handling, simulated excavations, and virtual tours of archaeological sites, USC undergraduate volunteers provide students with the opportunity to explore ancient civilizations throughout the world and to further their critical thinking skills. These interactive sessions allow students to understand the importance of conservation by comparing modern societies to those of the past. ARC Smart also serves as a curriculum enrichment program for the California Content Standards Exam in Social Studies. Results from immediately after the program show significant growth in learning and interest in the subject matter. The effectiveness of this program is visible in the differential in test scores on the State of California Grade Eight standardized test between students who participated in ARC Smart during 6th grade and their peers who did not. This paper discusses the ways in which hands-on activities with archaeological material can enhance students' understanding of ancient civilizations.

[287] Obsidian Studies in Mendoza (Argentina): A Sinuous Way to Do the Things without Following the Rules

In this paper we present a synthesis on the changing view of obsidian use in west-central Argentina and central Chile over the past 15 years. When this obsidian-sourcing program started, there was limited information about the number of sources, their locations, usage, and accessibility. In a region of approximately 200,000 square kilometers, information was limited to that coming from El Maule source located on the international border between Argentina and Chile. In 1998, Michael Glascock and colleagues described a series of steps to follow when starting an obsidian sourcing study in a new region - steps that were not taken into consideration when we began our work. Due to the size of the area and the inductive approach we followed, there were a number of misunderstandings, over-interpretations and shifting views about the locations, circulation, and number of obsidian sources in the region. Building on this experience, we describe what we have learned during the research process and our current views.
Finally, we reflect on how we can improve our knowledge during the next few years.

Gifford-Gonzalez, Diane
[40] Structured Deposition: An Idea Whose Time Has Come in Africanist Archaeology
In the 1980s Moore, Hodder, Thomas, and others exhorted archaeologists to view refuse disposal as a culturally structured act. Since then, numerous studies in Europe and North America have developed theoretical and practical tools for implementing the study of such practices. Most Africanists have been slower to engage with archaeological deposits as both culturally structured in their content and, in many cases, strictly controlled their spatial placement. Because refuse deposits are also produced by acts that define links between household and community, they merit a new perspective. Building upon recent theoretical work by Ann Stahl, I offer what I believe is a productive approach to these products of everyday life. To illustrate their potential, I explore a remarkable divergence between ethnographically documented patterns of refuse disposal practices among recent East African pastoral groups and those documented archaeologically for pastoralists in the same area two to three millennia ago, discussing its possible implications.

[220] Exploring the Variability of Upland Prehistoric Sites in the Central Plains
A common perceptual model among researchers on the Central Plains is that upland sites represent mostly limited sets of activities, manifesting as small specialized camps, quarries, isolated finds or the occasional small mortuary mound. However, the DB site at Fort Leavenworth, KS and other similar occupations indicate that more substantial, multi-component habitations can also be present in certain upland settings. A review of prehistoric sites on the Fort Riley Military Installation, focusing on several sites that have been part of recent NRHP evaluations, explores the variability and research value of upland cultural resources. In particular, we explore the variability in the lithic debitage assemblages from these sites as well as other types of artifacts, such as lithic tools and prehistoric pottery. The diversity of the assemblages is measured using standard diversity indices, but this variability is broken down further with a discussion of the types of artifacts and attributes of artifacts comprising each assemblage.

[225] Advances in Archaeological Geographic Information Science: A Perspective from South Carolina
Archaeological applications of Geographic Information Science have witnessed many recent advances as archaeological datasets have become more and more automated and available online. With this burgeoning availability of data, models of cultures and their associated landscapes are being developed using increasingly complex methods and environmental datasets. As archaeological site samples increase and multivariate analyses take hold, existing models need to be tested with independent site samples and compared directly to new models employing advanced multivariate techniques. Methods for testing extant models, detecting changes in land-use through time, and for developing time-sliced and adaptation-based landscape models are demonstrated using data from South Carolina.

Gillenwater, Collin (SUNY Albany)
[188] Agency at Hacienda Pancota: Early Colonial Daily Consumption of a Contested Age and Material Culture
During the early colonial period in western El Salvador (A.D. 1580-1650), residents’ production and consumption patterns at Hacienda Pancota demonstrated agency during a politically and socially volatile period. Agency is defined in this study as the set of practices by which household members incorporated new cultural and material lifeways, but selected which parts to include and which parts to reject within the
household. Residents’ formal alteration of their doxa is evident archaeologically from an incorporation of new pottery types, vessel forms, and an increasing number of specialized activity areas within the household. Through spatial and typological analysis of Hacienda Pancota’s archaeological remains, the reinforcement of past traditions and use of new European technologies is archaeologically apparent. The resulting data generated from these analyses demonstrates that the household scale of analysis is a satisfactory method for understanding small changes in daily life that later become routinely emphasized and that alter the way residents perform household activities.

Gillespie, Susan (University of Florida)

[204] *The Commoditization of Jade at La Venta*

Objects made of “jade” (jadeite and serpentine) were premier symbols of wealth and status in Mesoamerica. With the exception of beads, they typically comprised quintessential inalienable possessions: exotic, rare, finely crafted, and unique artifacts endowed with personhood that were gifted and curated across generations. Surprisingly, the occurrence of jade objects at La Venta contradicts this conventional scenario. This is all the more significant because, as the principal Olmec capital in the Middle Formative (ca. 800-400 B.C.), La Venta has long been considered the dominant symbolic center that innovated the meanings and uses of jade in other parts of Mesoamerica for the next two millennia. Although the La Venta excavations yielded thousands of jadeite and serpentine objects, the vast majority of them were made in two standardized forms: celt and rectangular blocks. They appear to have been commoditized in the sense of common, repetitive, and exchangeable goods, rather than incomparable, unique or singular possessions. Furthermore, the serpentine blocks were incorporated into La Venta’s above- and below-ground architecture as both building material and medium of wealth. This paper examines the juxtaposition of commoditized and individuated forms of social jade at La Venta, a phenomenon massive in scale and never repeated elsewhere.

[117] *Keeping the “Truth” in Ground-Truthing: The Roles of Stratigraphy and Near-Surface Geophysics in Detecting Buried Earthworks at the Fort Denison Site Near Humboldt, Saskatchewan*

Near-surface geophysical surveys at Fort Denison document several semi-circular and linear anomalies surrounding a sandy elevated landform that constitutes a low-relief topographic high within the surrounding prairie landscape. These anomalies are consistent with military texts and homestead-era oral histories, which describe the construction of defensive structures around the 1885-era fort using earth materials. However, ongoing archaeological excavations have until recently exposed only ambiguous evidence for these earthworks in the form of undulating and obliquely-oriented clay-rich layers. A key geoarchaeological question is whether these clay-rich layers actually represent defensive structures. We investigate this question using multiple techniques, including high-resolution topographic mapping, detailed stratigraphic analysis, micromorphology, bulk sediment characterization, and luminescence profiling. The results of these analyses indicate that the majority of the clay-rich layers represent naturally deposited relict aeolian dunes. Nonetheless, a 5.5-meter long anomalous feature recorded during the 2013 field season is interpreted as cultural in origin, likely representing infilled fortifications that were originally stabilized using clayey sediments. The broader implications of our work include the importance of establishing an understanding of the depositional environment of archaeological sites prior to interpreting and ground-truthing remote sensing data.

[66] *Maintaining Social Cohesion in Classic Mimbres Pueblos*

The Mimbres Foundation focused on large Classic (A.D. 1000-1130) Mimbres pueblos to contextualize the spectacular Classic Mimbres painted pottery and to provide modern excavated samples that would address questions about site and social organization. Building on Mimbres Foundation data, we now know that Classic period sites were diversely organized as seen in site and room block layouts and in the presence or absence of ceramic work groups. We also have a rich data base with which we are examining social differences and similarities in an “egalitarian” society, that is, a society without elites.
and a strong centralized authority. In the face of the organization diversity that the architecture suggests, individuals with special roles, perhaps using the ideological unity that the Mimbres painted pottery designs suggest, may have helped maintain community cohesion and social integration.

[318]  Geologic Context of the Older-than-Clovis Archaeological Material in Area 15 at the Gault Site (41BL323)
The Gault site is a stratified, multi-component prehistoric site located northwest of Austin, TX. The site was repeatedly, and at times intensely, occupied in all major periods of the prehistoric era in Central Texas. The current excavation block, Area 15, has yielded evidence of an older-than-Clovis component. Standard sediment and soil analyses as well as soil micromorphological observations were used to analytically examine sedimentary processes, pedogenic qualities of the soil, and effects of post-depositional processes on the sediment. The sand- and gravel-rich deposits containing the older-than-Clovis archaeological material stratigraphically underlie the fine-grained sediment containing the Clovis-aged component. The results of this study support the preserved context of the older-than-Clovis archaeological material.

[308]  The Social Geography of Florida’s Late Archaic Shell Mound Gatherings
In the middle St. Johns River valley, the adoption of pottery technology corresponded with the construction of Florida’s largest shell mounds during the Late Archaic Orange Period (4600-3600 cal BP). Radiocarbon data indicate that pottery use in this region was initially restricted to these mound contexts and involved the deposition of large, elaborately incised vessels within mounded shell deposits and into the water alongside them. At the same time, there was an apparent steep decline in the consumption of rare, nonlocal objects such as bannerstones and groundstone beads, which formed prominent constituents of multiple late preceramic mortuary mounds. In this paper, I combine chemical (NAA), mineralogical (petrographic) and techno-stylistic data from Orange sherds to argue that pottery entered into the region as an important exchange medium and quickly supplanted these other materials as the primary social technology for maintaining extraregional interaction networks. I further contend that Orange shell mounds constituted major nodes within these networks, functioning as large-scale gathering places that connected Late Archaic communities from across Florida.

[343]  Re-examination of an Ancient Game Drive Using Modern Technology: A GIS Analysis of the Flattop Mountain (5LR6) Site, Rocky Mountain National Park, Colorado
The National Park Service contracted with ERO Resources to resurvey and map one of the iconic archaeological sites in Colorado and the Southern Rocky Mountains— the Flattop Mountain Game Drive system (5LR6). Situated in an alpine environment above tree-line, the system was first recognized many decades ago, although it wasn’t until the pioneering work of James B. Benedict in the early 1990s that the game drive system was fully documented using a combination of pedestrian survey and aerial photography to map the site. During field work in the summer of 2013, ERO added new features and confirmed the accuracy of Benedict’s original map. Incorporating this information into GIS, we examine how the intricate system of walls, blinds, and cairns constructed through time was used in conjunction with topography, prevailing wind direction, and the knowledge of animal behavior to hunt large ungulates from the Early Archaic through the Late Prehistoric periods.

Gilpin, Dennis (PaleoWest Archaeology)

[18]  Family, Community, and Regional Social Interaction among the Diné of the Tohlakai Area Archaeological and ethnographic studies in the Tohlakai area for the Navajo-Gallup Water Supply Project have elicited data on Diné social interaction ranging in time from the return from Bosque Redondo in 1868 and ranging geographically from the San Juan Basin of New Mexico to the Kaibito Plateau in northeastern Arizona, more than 200 km away. The Tohlakai area was an important farming area during the early Reservation period, and it drew numerous seasonal farmers with fairly distant kin ties to the
Tohlakai community. At the same time, one individual from the community (John Daw) was influential in re-establishing a Diné presence on the Kaibito Plateau, even as he and his descendants maintained ties with relatives in Tohlakai who established prominent lineages manifest in archaeological sites and residential complexes in the southwest San Juan Basin. The social history of the Tohlakai area is a significant case study in the dynamic social organization of the Diné during the Reservation period.

[332] Consumer Reports: A Comparative Study of Cooking Pottery from Late Bronze Age Greece

Cooking pottery is a broadly distributed commodity in Bronze Age Greece. At the end of the Late Bronze Age (ca. 1200-1100 B.C.E.), there are a number of cooking pottery manufacturers, but none are more prominent in the archaeological record of central Greece than those from the island of Aegina in the center of the Saronic Gulf. Recently, cooking pottery of Aeginetan origin was uncovered at the site of Kontopigado on the western coastal area of Attica. Kontopigado is a pottery manufacturing center with its own distinct cooking vessel production tradition. The presence of used Aeginetan cookware at a site where cookware is produced elicits numerous concerns about consumer choices in antiquity. In this paper we compare the cookware sets from Kontopigado to the Aeginetan variety. Employing an integrated multi-technique methodology, we aim to compare and contrast cookware in form, fabric and technology from both production traditions. In an attempt to identify, characterize and understand the technological choices potters make during production, we strive further to observe and interpret the actions of the consumer when presented with the burden of choice.

Gingerich, Joseph (Smithsonian Institution/NC State University)

[133] Understanding the Role of Standardization in Flake Tool Production and Use

As stone tools are often the most common remnant of prehistoric behavior, understanding their use and mode of production is important for interpreting past lifeways. Examining when and how people organize technology in mobile societies has led to a tremendous body of literature. While design, portability, and mobility strategies are major themes in most technological studies of hunter-gatherers, aspects of tool design, and specifically the role of standardization, has played a smaller role. In this paper, I examine variation in Paleoindian tool assemblages from eastern North America to explore the conditions under which the standardized manufacture and selection of tool blanks occur.

Giomi, Evan (University of Arizona)

[231] Potential for Piro History along the Lower Rio Grande at Tiffany Pueblo

Research on the history of the late pre-contact and early Colonial periods along the lower Rio Grande in New Mexico is in an impoverished state, perhaps due in part to the abandonment of the region by Pueblo peoples after the 1680 Pueblo Revolt. However, a descendent population of the Piro people who occupied the region exists in the present. I argue that further archaeological study of the Piro region is necessary not only to better understand this component of history, but also to better recognize the persistence of indigenous cultures. Additionally, current archaeological interest in the 1680 Pueblo Revolt can be aided by this research, which is a relevant component in understanding the historical moment of the Revolt as well as the totality of colonial and indigenous relationships in the Revolt period. I aim to identify key issues in the study Piro history, in part through an examination of artifacts obtained by surface collection at the site of Tiffany Pueblo. In particular, better articulation of Piro ceramic chronology is a necessary starting point for many of the most relevant archaeological questions, especially considerations of changes in demography and organization of labor due to Spanish colonialism.

Giordano, Celeste (University of Nevada Las Vegas) and Liam Frink (University of Nevada Las Vegas)

[160] The Effects of the Traditional Yup’ik Seal Poke Storage System on the Safety of Seal Oil Consumption

Only a handful of studies have systematically investigated food storage and processing techniques in Alaska where many of these practices continue to be critical today. The seal was a mainstay in the Arctic economy and ideology. Its bones were used as tools, meat provided sustenance, and rendered oil was used as fuel for lamps, as an essential condiment, and a common medicine. And the skin served another
critical purpose, as a storage and rendering device—a use commonly overlooked. Today, the traditional seal poke storage system is being replaced by plastic, airtight buckets, not designed for food storage. There are numerous examples of serious health consequences when local traditional food processing techniques that have developed over many years are ignored, such as scurvy and pellagra associated with major vitamin deficiencies. In Alaska, the majority of attention paid toward traditional food processing techniques so far has been cursory and largely negative, citing numerous food safety concerns. Here we present the results of an ongoing investigation of this particularly complex and interesting storage system that, until now, we have known little about - the seal poke storage system.

[286] A Big Fish Tale? Assessing the Impact of Restricted Element Analysis in Archaeological Fish Studies

Archaeological fish studies in the tropical Pacific and New Zealand have commonly relied on a methodological approach that restricts analysis to a set of five paired cranial elements, plus so-called “special bones”. This method has been critiqued for reducing taxonomic richness and altering relative abundances as compared to approaches incorporating most or all diagnostic elements in the skeleton, with consequences for reconstructions of diet, ecology, fishing strategies, and more. Here, I assess whether these issues hold true for a Caribbean fish assemblage from the prehistoric site of Sabazan (AD 400-1400), Carriacou, Grenada. I compare analytic results obtained using the restricted element method to those based on analysis of all potentially diagnostic bones, including elements of the pelvic and pectoral girdles and the vertebral column. The latter, inclusive approach resulted in the identification of > 40 discrete elements from 34 mutually exclusive taxa within 23 bony fish (Actinopterygii) families. I build on previous critiques of the restricted element method by evaluating its analytic impact for different screen-size fractions (6.4 mm and 1.6 mm). In addition, I consider the implications for the detection of tuna (Scombridae) and small, net-caught taxa (e.g., Clupeidae, Carangidae) in the assemblage, as well as the identification of fishing zones exploited.

[197] A View from the South: Some Comparative Notes on Guayabo, Rivas, and the Sierra Nevada de Santa Marta

For more than 50 years, Tairona architecture and society have been compared offhandedly to similar architectural and sociocultural patterns occurring at archaeological sites such as Guayabo and Rivas. Despite these frequently cited similarities, very little effort has been put in towards establishing more rigorous, and perhaps more interesting, comparative analyses. On the basis of recent research in the Sierra Nevada de Santa Marta, I examine a few areas of inquiry and comparison between Northern South America and Central America that may move the discussion towards more productive analytical lines.

Giraldo Tenorio, Hernando (University of Pittsburgh)

[311] Religion, Wealth Accumulation and the Development of Social Inequalities in the Prehistoric Colombian Southwest

Archaeological research in northern South America has established that religion, rather than economic control, was the principal mechanism by which social inequalities were created and maintained in a number of regions. However, Maleagana, the largest known prehispanic village site in the flat valley of the Cauca River of southern Colombia, stands out as a possible exception to such a pattern. Clear differences in wealth in the burial contexts during the Early El Bolo Period (400 B.C.-A.D. 800) support this view. This paper discusses household differences in wealth consumption and their connection with the production of luxury and utilitarian goods as a mechanism for creating and maintaining social inequalities.

[287] Reflections on Obsidian Studies and Their Contribution to Mesoamerican Archaeology
Despite the fact that the sources of obsidian in Mesoamerica are geographically restricted, the use of obsidian in pre-Columbian Mesoamerica was widespread. Obsidian played an integral role in the daily lives of the Mesoamerican people and in many of their religious practices. Obsidian was used to produce sharp-edged cutting tools, scrapers, weapons, figurines, jewelry, mirrors, and many other objects. The abundance and variety of uses for obsidian were likely to have been a contributing factor in the near absence of metallurgical development prior to the arrival of the Spanish. Studies of obsidian have helped archaeologists reconstruct many aspects of pre-Columbian life, including technological development, long-distance trade, ritual customs, and sociocultural structure. This presentation will reflect on the history of obsidian studies and their contribution toward our current understanding of archaeology in pre-Columbian Mesoamerica.

[85] The Maritime Maya: Ambivalence, Ambition, and Adaptation across Millennia
Coastal communities in the Maya lowlands played a myriad of roles in the ebb and flow of political, economic, and social formations over the past 3000 years, yet these roles have remained along the periphery of Maya studies. While often small in size when compared to their inland neighbors, Maya coastal sites were integral to the early development of complex polities in the Formative period, provided refuge following the Classic Maya “collapse” in the 9th century A.D., and were home to cosmopolitan residents engaged in long-distance trade on the eve of Spanish contact. Though ever present, Maya coastal sites were atypical – perhaps even idiosyncratic – in terms of how they were imagined and lived-in by the Maya. Both social and environmental factors conditioned human-coastal relations, as dynamic markets, political forces, and ecosystems required constant negotiation. While our research is based along the north coast of the Yucatán Peninsula (at the sites of Vista Alegre and Conil), this paper uses our research as a point of departure to discuss more broadly the challenges faced, and opportunities pursued, by the maritime Maya as they adapted to their changing coastal landscapes over the millennia.

[289] Population Aggregation and Community Center Organization: Comparing the VEP North and South Study Areas
Over the course of centuries, Pueblo settlement organization, for a variety of reasons, became increasingly aggregated and villages became larger, especially after the turn of the fourteenth century. This process was historically rooted in local dynamics, but also was influenced by immigration, religious (sociopolitical) reorganization, and demography. This paper compares the scale of aggregation, changes in roomblock arrangements, and the role of public architecture in the largest villages and towns in the two VEP study areas. In the VEP north study area, aggregation was episodic and the size of community centers ranged between 50–600 rooms. In the VEP south study area, aggregation increased in scale more continuously over time with the largest Pueblo towns reaching a size of about 2,500 rooms. Public architecture informs on village and religious (sociopolitical) organization since it is influenced by ritual practice, demography, and economy as well as other factors. We pay particular attention to village organization and size during the pre-migration period in both study areas to assess the extent to which settlement and organization in the south study area may have been influenced by immigration in the
subsequent period.

Gnivecki, Perry  
[269]  From Ecofact to Artifact: Wooden Artifacts from the Dead Man’s Reef Site, Grand Bahama, Bahamas

In the late 1990s, Lucayan wooden artifacts were recovered during excavations of the Deadman’s Reef Site, a fifteenth century site located on Grand Bahama, Commonwealth of the Bahamas. The finds offer insights into the use of wooden objects in northern Lucayan domestic and religious life; Lucayan artistic and symbolic expression; Lucayan perceptions of the animal world; patterns of wood selection for different kinds of objects; techniques of prehistoric wood carving; and preservation conditions allowing for wooden artifact survival in an open-air depositional environment.

Go, Matthew (Simon Fraser University)  
[103]  The Backbone of Moche Society: Spinal Degenerative Joint Disease and Its Utility in Reconstructing Prehistoric Moche Stratification

This investigation seeks to explore variation in the quality of life among Late Moche individuals at San Jose de Moro, Peru, as reflected in the severity of spinal degenerative joint disease (SDJD). The sample includes 67 individuals excavated from 1995 to 2013. The vertebral elements were examined at several spinal joints for lesions indicative of SDJD, including marginal osteophytes, lipping, surface pitting, sclerotic new bone formation, eburnation and Schmorl’s nodes. Specific vertebral articulations analyzed were individual zygapophyseal facets, intervertebral symphyses, and articulations with the costal elements. Severity was visually assessed through an ordinal scale of 0 to 3. Data collection was limited to adult remains from confirmed Late Moche contexts, and individuals were categorized by age and sex in order to control for these variables. The relationship between spinal health, social status and sex is explored. Preliminary analysis suggests higher levels of stress in the cervical and lumbar spine of lower class individuals than in those of middle and elite social status.

Godfrey, Kipp (Pacific Lutheran University) and Bradford Andrews (Pacific Lutheran University)  
[160]  Berkeley Rockshelter Lithics: Inferences about the Prehistoric Use of the Mount Rainier Area Throughout human prehistory, hunting and gathering has been the predominant subsistence strategy. These societies can be conceptualized using the theoretical forager-collector continuum developed by Lewis Binford. In the Pacific Northwest, this continuum has been applied to model the temporal dynamics of prehistoric occupation of this region. It has been suggested that groups in this area shifted from foraging to increasingly more intensive collector systems beginning around 5000 B.P. Deposits at the Berkeley Rockshelter in Mount Rainier National Park post-date 2000 B.P. Therefore, assuming the people who used the site were collectors, its artifacts were analyzed to try and determine its possible function as part of such a subsistence strategy. According to Binford’s collector site types, the Berkeley Rockshelter appears most consistent with a seasonal field camp. The lithic debitage and stone tool data suggest occupation by specialized task groups likely focused on seasonal subalpine to alpine upland hunting. The evidence for this interpretation can be found in the lithic debitage that heavily reflects late stage flaking typically associated with finalizing implements for use. The projectile point artifacts recovered are also consistent with late stage flaking indicating retooling and refurbishing.

Godoy, Renata (PhD, University of Florida)  
[331]  Archaeotourism in the Brazilian Amazon: How and Why Have Communities Been Involved?

Recently it has become more difficult to ignore archaeologist’s responsibilities to the public, particularly as they relate to ethics, values, economy, politics, and ideology. Archaeological tourism plays a major role in this debate, especially where local communities are actively invested stakeholders. It is well known that notable archaeological heritages around the world are often adapted to tourism without any sort of planning. Because of the potential irreversible impacts that may occur, understanding long term effects of tourism on cultural heritage is urgent. On the other hand many agree that despite its sometimes negative and destructive nature, conscious and collaboratively planned heritage tourism can provide not only
financial support for heritage preservation, but also help improve public awareness. The research presented in this symposium seeks to identify effects of archaeological tourism on local communities as well as on the cultural remains by contrasting rapid ethnographic assessment data collected at two sites—one with planning in place and the other without any formal planning—in the state of Para in northern Brazil. Is previous planned archaeotourism less harmful? Are local communities active stakeholders? How and why have communities been included in these processes?

[245] Subsistence Economies in Marginal Areas with Natural Constraints: Interactions between Social Dynamics, Resource Management and Paleoenvironment in the Sechura Desert, Peru
The study of subsistence economies is fundamental to understanding social dynamics and economic interactions between prehispanic complex societies, particularly maritime communities. It also helps us understand how humans have adapted to constrained environments and how landscape changes could have affected subsistence. The Sechura Desert, located in the far north of Peru, is a strategic area that presents a composite geomorphology. It is also located at the transition between warm and cold water currents. Situated at the interface between environments and societies, this research aims to define the spatio-temporal relationships between human activities and environmental changes over the last two millennia and to reconstruct climatic changes which may explain the variability, in time and space, of human settlements and resources. The methodological approach of this study is multidisciplinary, multiscalar, spatialized and diachronic. In this paper, we present the preliminary results of this research drawing on archaeological excavations of a fishing site dating from the Early Intermediate Period. These data allow us to study the impact of landscape modifications on the territorial organization of sedentary populations occupying marginal areas, who were closely dependent on the natural environment.

Goff, Sheila
[68] Collaborative Relationships and Amazing Museum Collections Combine to Bring Archaeology to Broader Audiences
The History Colorado Center is tasked with bringing an understanding and appreciation of Colorado's past to our visitors. This paper discusses the development of our most recent exhibition to that end. The exhibition focuses on the interaction between the natural environment and the people who have lived in Colorado, while asking visitors to consider how the choices they make for the future can be informed by choices others made in the past. The exhibition demonstrates the relevance of archaeology to broad audiences and funders by elaborating the story of ancestral Pueblo people, who for centuries successfully faced the challenges presented by the natural environment in the Mesa Verde region. We collaborated with archaeologists and Pueblo cultural preservationists from New Mexico and Arizona to present cutting edge research interpreted from multiple perspectives to our target audience-families with children. The exhibition is supported by artifacts from two of the four major Mesa Verde archaeological collections. The collaborative effort to ask our visitors to ponder Colorado's history through an environmental lens at a time when we are facing environmental challenges today has attracted considerable support from private and public funders. Other institutions may benefit from learning about our experiences.

Megalithic Symbolic Burials: A Regional Perspective from Tamilnadu, Southern India
The Megalithic burial tradition of Southern India (1000 B.C–A.D. 300) was a widespread practice with many regional variations in its architectural features. The Symbolic or Commemorative burials (the regional terms used for burials with no skeletal remains) were part of a common practice in the megalithic landscape of southern India. In this paper I will focus on a regional analysis from Tamilnadu to better understand the ritual significance of this burial tradition by looking at the “symbolic burials.” Previous studies have focused on the socio-economic conditions of megalithic remains by analyzing the prestige or high status goods and concluded that the burials of early historic period in southern India showed signs of hierarchical social organization. However, I would like to present a different perspective. There were numerous burials in which the only types of grave goods were basic burial pots. Even in cases where interments of high status grave goods are present, the signature pottery interned was similar in most of these burials. Thus the symbolism of this mortuary ritual must have been more important to the society than its usage as an arena for portraying social status.

Applications of Metal Detection in Analysis of Illegal Slave Trade Sites in Nineteenth Century Guinea
For centuries, European traders have influenced and altered the African landscape, playing a major role in identity formation, group memory, and trade relations. To enhance our understanding of the relationship between European traders and local citizens through occupation of space, experimental metal detection was employed at three sites located along the Rio Pongo in Guinea. Situated in an isolated region of West Africa, these clandestine sites were active throughout the illegal slave trade of the nineteenth century, further complicating issues of cultural entanglement. Through the identification of high-density metal deposition zones, we are better able to examine the spatial organization of these multicultural interactions. By integrating these preliminary data with GIS mapping we developed a clearer understanding of the relationship of these disparate groups as reflected through occupation of space.

Archaeology Should Be Engaging
Is archaeology only interesting to the public when it involves tombs, temples, or superlative claims of extraordinary discoveries? Should archaeologists only be rewarded in academia for publishing in elite journals or theory-laden books disseminated to a limited academic audience? In this paper the authors wrestle with the reality that most archaeology takes place in small-scale sites and with discoveries that consist of little more than lithic debris and smashed pottery. In many places such sites may be seen as impediments to development, a resource to be mined for construction fill or the acquisition of personal knickknacks, or an untouchable component of local history. Moreover, when we disseminate our research we are typically driven by the realities of academia and its reward system to publish in academic journals and books, media that are typically of limited interest to the many publics we serve. How can archaeologists explain to academics, the wider public, and the communities where we work our interest in such sites and discoveries? Given a reality that there is limited time for research, writing, and publication, how can we balance professional development and issues of engagement with many publics?

Liminal Plazas and Processional Paths in Tiwanaku Temples: Divergence, Convergence, and the Rule of Three at Omo M10

Reconstructing liturgical movement from plaza architecture can illuminate social processes within Andean expansive states. Extensive excavations in the uniquely preserved Omo M10 Tiwanaku temple shed new light on room function and access patterns to different parts of the temple. On one hand, the Omo excavations confirm an axial series of seven doorways leading from public plazas to the sunken court, presided over by stelae and audiencia structures. This supports Conklin’s characterization of an elite “Doorway cult”, funneling access from increasingly restricted public plazas to an exclusive inner sanctum. However, passage along the central axis was interwoven with separate bilateral pathways which connect to a series of independent walled patio groups that may have functioned as chapels for separate sacrifice and cultic activities. Plaza access alternated between single and triple entryways, suggesting that plazas were liminal places where the central and two lateral groups converged and diverged as they progressed through the structure. Implications for Tiwanaku social structure are considered in light of other examples of triple entryways in Tiwanaku architecture, Kolata’s suggestion of “Taypi” as structural amalgam of center and complementary halves, as well as implications of gender, moiety, and other bilateral complementarity within Tiwanaku.

Goldstein, Amy (University of South Carolina) [263] Locating a Household in Time: Temporal Difference in Architectural Types at the Etowah Site

During the summer of 2013, a field school under the direction of Dr. Adam King completed the first excavations at the Etowah site in nearly two decades. Etowah had multiple occupation periods spanning from A.D. 1000 into the early historic period. Interestingly, this occupation was not continuous, with two distinct abandonments around A.D. 1200 and 1400. One of the main goals of the 2013 excavations was to examine two different house construction types shown in a gradiometer survey: single-set post houses and wall-trench houses. Different forms of house architecture and the arrangement of those houses is one aspect of material culture that helps us understand how communities and households were organized during each period of Etowah’s occupation. In the research presented here, ceramic assemblages recovered during the 2013 excavations are used to assess temporal differences in architectural types. Specifically, these data are used to test the assumption that wall trench buildings date to the earliest phase of Etowah’s occupation while single-set post buildings date to the later two occupation periods. Besides giving approximate dates for the structures, the spatial and temporal patterning of these ceramics within specific architectural types can yield insights into community formation throughout Etowah’s multiple occupations.

Gómez, Esteban (The Colorado College) [198] Colonial Legacies and the Historical Marginalization of Eastern El Salvador

In thinking about colonial entanglements and the colonial legacies that take place thereafter, landscape and place become useful terms and necessary concepts for understanding how people experienced and actively participated in different colonial settings. The research that forms the basis of this paper involves the historical documentation and archaeological excavation of Conchagua Vieja, a Lenca settlement on the island of Conchaguita, in the Gulf of Fonseca. Landscape and place are used in this paper in order to explore the complexities that characterized the colonial situation in eastern El Salvador, as well as to better understand the connection between El Salvador’s colonial past and its present condition.

Gómez Zúñiga, Pastor
Las investigaciones sobre las sociedades ubicadas al sur del Área Maya son tan escasas que actualmente es difícil analizar su relación con la conocida como Región Sureste de Mesoamérica. Esta situación es particularmente deficitaria en el campo de la etnohistoria, donde hay pocos trabajos acerca de la geografía política de la Región Central de Centroamérica, un espacio hoy día repartido entre los estados de Honduras y El Salvador, y que al momento de la conquista lo ocupaban, principalmente, poblaciones de filiación Lenca. El desconocimiento de los grupos allí asentados es tan marcado que el arqueólogo George Hasemann, en la década de 1990, propuso clasificar la Región Central de Centroamérica provisionalmente como una región independiente, a la espera de nuevos datos que permitieran evaluar su relación con Mesoamérica y el Área Intermedia. El presente trabajo, basado en una revisión sistemática de documentación del siglo XVI del Archivo General de Indias de Sevilla, estudia las unidades políticas Lenca del centro y occidente de Honduras, y tiene como objetivo principal aportar nuevos datos que contribuyan a debatir la relación entre la Región Central de Centroamérica y la Región Sureste de Mesoamérica.
1940s, Brazilian authorities have forced indigenous communities to live on reservations, causing dozens of ethnic groups to leave their original territory where there remains an important heritage formed by old villages, cemeteries, rock art and other ethnic markers. Specific features in the landscape constitute the home of spiritual, demiurgic and shamanic entities, responsible for keeping a spiritual order of cultural systems. In such case, the challenge for archaeology is not only to identify human markers of an ancient presence but also symbolic remains embedded in such sacred sites. The case studies introduced here exemplify how ethnoarchaeology contributed legal and political agreements between indigenous populations and Brazilian authorities. Initially we focus on how the Brazilian government recognized sacred spaces as national heritage in 2009. Since 2011 systematic development of normative tools culminated in a regular obligation of detailed ethnoarchaeological studies on indigenous lands, resulting in a new phase of duties led by researchers, indigenous communities and the government.

**Bats, Bones, and Bells: Towards a Greater Understanding of Ancient Maya Chultun Use at Ka’Kabish, Belize**

Over the last two seasons the Ka’Kabish Archaeological Research Project has carried out a program investigating chultuns. During the 2012 field season a chultun in Group B was excavated which contained the burials of two individuals. This last season, a chultun near Group C yielded the remains of at least four individuals. The most important discovery was the burial of an individual with 33 copper bells and 8 copper rings along with jade and shell beads. Not only does the copper indicate a Terminal or Post Classic date, but also indicates the presence of an elite individual. This is significant because Puleston in particular promoted the idea that chultuns only occur in residential areas as opposed to public space. He reasoned that this indicated that chultuns must have a utilitarian function associated with commoners. Our data, as discussed here, supports the idea that chultuns are associated with all strata and the function of these features is still very open.

**Maize Processing and Grinding Technology at Cerro Junaqueña, Chihuahua, Mexico**

Preparing dried maize during the Early Agricultural period (2100 B.C.–A.D. 200) presents a number of technological challenges that are not well understood. Processing dried maize is extremely labor intensive, particularly in the absence of ceramic cooking vessels. Models of human behavioral ecology suggest that maize-processing technology must be efficient in order for maize to be added to the diet. At Cerro Junaqueña (1300 B.C.–1100 B.C.), early farmers integrated substantial amounts of maize into the diet along with wild foods. Cerro Junaqueña mano and metate sets have particular morphological characteristics that appear to be well suited for processing substantial amounts of dried maize. The massive, deep basin metates represent a form that is transitional between traditional Archaic period basin metates and later trough metates. The complimentary manos are large, one-hand forms. It is likely that at this early time period that maize endosperm tended to be more flinty than floury, which would have been more difficult to grind. We describe maize processing experiments that attempt to evaluate the efficacy of this technology.

Las Mesas Rituales de Piedra de Estilo Azteca: tres ejemplos poco conocidos
La escultura de estilo azteca floreció en el centro de México pocas décadas antes de la llegada de los españoles. Su impresionante desarrollo se ve demostrado por la diversidad de formas, ya que en este arte es bastante común observar humanos y animales. Además de ello no es extraño que se encuentren plasmados en piedra instrumentos indispensables para la liturgia; en este trabajo queremos concentrarnos en tres ejemplos particulares y la iconografía que muestran. Hablando de manera general se trata de cubos de piedra de baja altura, que fueron utilizadas como mesas rituales, sobre los que se colocaban los preciados dones para diferentes seres. Los tres ejemplos que aquí se examinarán provienen de diferentes lugares de la Cuenca de México, aparentemente del mismo periodo y estilo. Se trata de imágenes que representan a diferentes deidades realizando múltiples actividades. Allí podemos observar seres específicos como a Xiuhtecuhtli, dios del fuego; Itzpapálotl, una diosa guerrera; además una interesante escena que muestra a cinco deidades alrededor de una bola de heno. Destaquemos que dos de estas interesantes esculturas no han sido publicadas hasta el momento.

The Asturian after Geoff Clark: New Perspectives, New Evidence
Geoff Clark’s doctoral dissertation and the fieldwork previous to it, in the late 60’s, meant a new direction for Mesolithic research in Northern Spain. Based on a limited series of sites and materials, he showed the power of a well-defined theoretical framework to elucidate the main problems posed by former research on this intriguing “culture”. More than four decades later, new theoretical approaches and new and better- preserved shell midden sites allow us to follow and develop the main lines of his seminal investigations. In this direction, the frequency of human burials, the value of shells as high resolution climatic indicators, the use of shells as instruments, and the problems linked with the transition to Neolithic arise as new challenges in current research.

Paleodemography of the Upper Columbia: Detecting Regional Population Trends in the Interior Pacific Northwest
The first evidence of human settlement into pithouses and aggregated villages in the Upper Columbia region of the interior Pacific Northwest occurs ca. 3,800 cal B.P. Subsequently, over the period of time from 3,800 cal B.P. to contact, population levels appear to have peaked twice, with a depopulation event at approximately 2,000 years ago. In this paper, we explore radiocarbon and archaeological datasets from the Upper Columbia to analyze statistically the trends for indications of rising and falling populations, and give a measure of the probability of seeing truly separate peaks in population, given imperfect data. We also examine the potential reasons for a large scale depopulation of the Upper Columbia River system at ca. 2000 cal B.P.

Patterns of Surface Salinization and the Identification of Subsurface Features at Girsu, Dhi Qar Governorate, Iraq
High concentrations of salts on the Mesopotamian floodplains, synonymous with the collapse of early complex societies, still threaten agricultural productivity today. But a recent site visit to the ancient city of Girsu (modern Telloh) in southern Iraq suggests that patterns of surface salinization also present opportunities for remote sensing and future archaeological survey. Following periods of heavy rain, subsurface mudbrick, a principal building material in antiquity, shrinks and swells from moisture, ultimately fracturing. Because of capillary action, salts drawn into and out of these fractures are differentially driven to the soil’s surface, leaving silhouettes of ancient architecture above ground. Inspection of Girsu after torrential rains made this apparent, as possible features presented distinct
arrangements in unexcavated areas of the tell, most notably what might have been a city wall. While our poster considers this phenomenon’s ability to help archaeologists selectively target excavations on the ground, it focuses on the potential for remote sensing to reveal subsurface architectural features through the recognition of patterned salinity on satellite imagery, an especially promising contribution to a region where fieldwork remains untenable. Observations recorded at the site are compared to multi-seasonal imagery to assess pattern consistency.

Goodmaster, Christopher (Versar/GMI), Erin Helton (Versar/GMI) and Mark Willis (Mark Willis Archaeological Consulting) [248] Ancient Sites in 21st-Century Environments: Three-Dimensional Digital Documentation of Panther Cave
Recent digital documentation efforts at Panther Cave (41VV83) have yielded a detailed record of current site conditions and provide a wealth of geospatial data pertinent to the prehistoric art preserved at the site. Three-dimensional laser scanning (LiDAR) and photogrammetry were integrated to record a highly accurate digital model of the rockshelter and its immediate environment. The resultant digital models provide not only a detailed record of Panther Cave, but will also serve as a basis for the spatial analysis of the site and its associated rock art. This documentation effort provides a robust corpus of data for use in the digital visualization, analysis, and management of the site. Potential research questions will be discussed and a framework for applying these data in geospatial analysis, site management, and public education will be presented.

Goodwin, Whitney (Southern Methodist University) [190] New Lines of Evidence for Examining Identity Expression among Prehispanic Coastal Populations of Northeastern Honduras
Recent research in coastal northeastern Honduras, including the Bay Islands, has started to disentangle how indigenous populations expressed cultural affiliation, highlighting the existence of widely dispersed populations connected through enduring social and political networks. Broad cultural affiliations persisted from at least the Early Selin Period (A.D. 300-600) through contact, uninterrupted but not unchanged. The direction and nature of contact and influence among these populations and other groups to the north and south have been traced mainly through changes in ceramic traditions. These studies have aptly emphasized local developments over externally imposed changes and recognized the fluid nature of boundaries both spatially and temporally. Adding to that discussion, this paper presents data from the initial stages of a regionally focused project, with new information from the island of Roatán and related mainland coastal sites. Current research seeks to explore varied lines of evidence, including analyses of soils, adding more fine-grained data to highlight subregional diversity and change over time. In the present, Roatán and the coast are connected by parallels in recent growth in the tourism industry and, consequently, archaeological resources are under immediate threat of development in both cases, underscoring the urgency of research here.

Gopnik, Hilary (Emory University) and Clemens Reichel (University of Toronto) [329] The Godin VI Oval and Uruk’s Sphere of Influence
Excavations at Godin Tepe in the Kangavar Valley (Zagros Mountains, Western Iran) have added substantially to our knowledge of the extent to which the “Uruk System” exercised control over areas in Syro-Anatolia and Western Iran, with which economic interactions are known to have occurred. Classified by Algaze as an “outpost” of the Uruk System, the so-called “Oval” of Godin’s Level VI was built as a walled enclosure within and separated from a preexisting local settlement. Its architecture, largely constructed with local building conventions, is juxtaposed by a material assemblage that in part betrays strong Uruk traditions, notably among its bureaucratic tools (seals, tokens, numerical tablets). This paper will evaluate the ceramic assemblage from Godin, typologically consisting of an almost even mix of Uruk and local types, in light of recent INAA analyses, allowing new insights into the modes and mechanisms of interaction between a local culture and the wider sphere of Uruk’s zone of influence.

[131] Eastern Beringian Toolstone Procurement and Selection: A Case Study from the Nenana Valley

Two multicomponent sites in central Alaska, Owl Ridge and Dry Creek, each possess two terminal Pleistocene-aged cultural components significant to understanding early human behavior in eastern Beringia. These components date to about 13.5-13 and 12 ka, respectively. Recently, I analyzed the lithic assemblages from these early components to examine raw material procurement and selection strategies and how they vary, with the ultimate goal of examining how this technological variability can inform on mobility and settlement in the Nenana Valley. Results indicate several striking differences between components and sites, and these results are presented in this paper.

Gorman, Alicia (UC Santa Barbara), Jelmer Eerkens (UC Davis) and Kevin Vaughn (Purdue University)

[19] Electron Microprobe Analysis of Nasca Polychrome Ceramic Pigments

This study investigates the mineralogy and physical structure of pigments on Nasca polychrome ceramics using electron microprobe analysis. Physical structure characteristics studied include relative uniformity of mineral grain size and mineral grain roundedness, which are tested as proxies for standardization of pigment production. We focus on mineralogical uniformity in order to more closely align our focus with selection criteria of ancient Nasca potters. Our study shows that Nasca 3 and 4 pigments are relatively uniform while Nasca 5-7, Loro, Wari, and the Late Intermediate Period are more variable. Interestingly, while Wari was not as uniform as Early Nasca pigments, it was less variable than Loro. We interpret these results in light of other archaeological evidence, including previous studies on Nasca fineware ceramic paste, as evidence for fluctuating numbers of ceramic production communities. The results have implications for how we understand centralization of ceramic production in the region, especially in the context of the rise and fall of the Nasca and Wari civilizations.

[215] The Afterlife of Industrial Landscapes: Strategies for Cultural Heritage Management of Ancient and Historical Mining Sites in Spain and Beyond

From the spectacular opencast gold mines of the Roman period that destroyed whole mountains, to the silver mines that supplied coinage to the Islamic caliphate in Cordoba, to the British colonial copper mines that transformed the landscape of southwest Spain, mineral exploitation in the Iberian Peninsula has always been a major economic industry. The mines in Spain, some of which were exploited from early prehistory through the 19th century, help inform our understanding of the economic and cultural history of the region as a whole. Despite this, many ancient and historic mines and mining settlements have been left abandoned. Others have fares better. Using the examples of Las Médulas, the Linares-La Carolina Mining District, and Rio Tinto, this paper examines several successful strategies for cultural heritage management of industrial landscapes currently employed in Spain. These include private and state ventures at both national and local levels that help promote tourism and preservation of these important sites. Finally, this paper discusses the potential of using similar strategies for industrial landscapes in other parts of the world.

[192] The View from Laguna Holbox: Ancient Maya Fishing and Foraging along the North Coast of Quintana Roo, Mexico

This paper provides an overview of the marine faunal assemblage documented at the ancient Maya coastal site of Vista Alegre and its environs. Based on careful taphonomic differentiation between anthropogenic and natural deposits, we discuss the diverse ecosystems of the region as well as fishing and foraging techniques – and associated adaptive strategies – employed by the site’s inhabitants over time. Consideration is given to the taxonomy, size, and resulting biogeography of marine fauna. Results from Vista Alegre are incorporated into a diachronic comparison of zooarchaeological data from other coastal Maya sites across the Yucatan Peninsula to provide a broad view of fisheries exploited by the northern lowland Maya that is also informed by ethnohistoric and artifactual data from coastal sites.
Finally, we propose future zooarchaeological research that employs the historical ecology approach to study the complex interrelationships between the Maya and their marine environments along the coast of the Yucatán Peninsula.

Gradwohl, David Mayer (Iowa State University (Ames))
Like many other Plains anthropologists of my generation, I began my career as a “shovel bum” on IASP field parties. Without running water and electricity, we lived in tent camps that were sometimes flattened by summer storms. The weather was sizzling; the work was strenuous; the pay was pitiful. Adding insult to injury, the RBS crews, and those of most cooperating agencies, were restricted to males. Despite this near monastic ambiance and “no frills” accommodations, we had the opportunity to train under some outstanding mentors, establish productive, long-term associations with colleagues, and explore some dramatic and significant archaeological sites.

Graesch, Anthony (Connecticut College) and Timothy Hartshorn (Connecticut College)
[230]  Cigarette as Artifact: An Archaeological Ethnography of Bars, Smoking, and Social Identity on the Urban Landscape
Archaeologists have long grappled with the complex relationship of material culture to social meaning and identity. Our research examines this relationship by focusing on a category of objects that are (1) frequently used in the social construction of identity and (2) regularly discarded on the urban landscape: cigarettes. Like comestibles, cigarettes are symbolically distinct from most other material culture in that they are not merely worn or used but rather physically incorporated into the body. It follows that ways of smoking (in general) and cigarette preference (in particular) can be framed as deeply personal ways of interacting with the material surround and thus, like food, objects of personal significance and even moral concern. Cigarettes are also among the most ubiquitous and tolerated forms of trash on the urban landscape, especially outside drinking establishments, where social identities are created, negotiated, and defended. Drawing on data collected at 24 sites, including over 30,000 artifacts, this poster highlights the ways that social group affiliation or social identity is reflected and/or indexed by the spatial distribution of more than 350 unique types of cigarettes.

Graf, Kelly (Texas A&M University, Department of Anthropology)
[23]  Early Modern Human Expansion North to Siberia and Beringia
Initial human settlement of northern landscapes was a major undertaking and certainly an exceedingly complex process. This was especially true in Northern Asia. In this paper, I review the record of human expansion north into Siberia above 55°N, specifically looking at human-adaptive strategies enabling this spread. Early modern humans had negotiated southern Siberian habitats soon after 50 ka. By about 32 ka they made it all the way to the Arctic. Initial incursion into the far north, however, may have been short-lived because as yet there are no archaeological sites unequivocally dating to 31-17 ka for this region. Further, sites postdating 17 ka evidence major technological and land-use reorganization. Ultimately, the data suggest Pleistocene peopling of northern Asia was episodic, taking tens of thousands of years and involving major shifts in adaptation to changing northern environments.

Graff, Emily (School of Anthropology, University of Arizona)
The Bioarchaeology of Peripheral Populations within the Mycenaean World: Ancient Kallithea Laganidia Cemetery near Patras, Greece

Bioarchaeological studies throughout the ancient Mediterranean often focus on palatial rather than peripheral settlement populations. The neglect of these outlying populations could misrepresent the demographic, cultural, and paleopathological understanding of the culture as a whole. This is particularly prominent within the Mycenaean civilization, which too often is defined by its well-known palaces like those at Mycenae, Pylos, and Tiryns. Thus the bioarchaeological agenda throughout the Mediterranean needs to include known peripheral populations in order to properly interpret and decipher the health, culture, and lifestyle of particular ancient groups. Moreover, many of these peripheral populations have been already excavated, but not studied. Ancient Mediterranean cemetery collections have been removed, stored or discarded and misplaced. Without the maintenance and study of these forgotten collections, archaeologists and bioarchaeologists will continue to be without data significant to further research and interpretation. This research focuses on the bioarchaeological data collected from five tombs belonging to a peripheral Mycenaean cemetery, Kallithea Laganidia, in the region of Achaea. The small sample of 38 individuals revealed much about the health, pathology, culture, and social stratification of an otherwise unknown Mycenaean population.

Graham, Elizabeth (Institute of Archaeology)

Mobility and Resilience: A Perspective from the Eastern Maya Lowlands

Circum-peninsular travel was a feature of eastern Maya lowlands coastal communities such as Lamanai and Marco Gonzalez, and the regularity of contact with non-local settlements and settings must have contributed to community diversity and outlook. It is true that stability was manifested in the continuity and persistence of coastal activity—both subsistence and commercial—from the Preclassic to early Colonial period, yet coastal communities changed a good deal in character over time, and some of these changes may reflect small-scale population movements. Some movements were distinctive to the coast, particularly in the Terminal Classic to Postclassic transition, whereas in other circumstances and times we seem to be seeing change on the coast as a response to the reorganization of local political entities and small-scale mobility on the mainland. Subsistence practices as well as access to products and trade routes changed, as did elite demands and how these demands were met. These ideas and other hypotheses will be discussed in the hope of shedding light on prehispanic urbanization and the life cycle of cities.

Inside a Mediator’s Toolkit: Reframing Cultural Resource Compliance in the Context of Alternative Dispute Resolution

Archaeologists who pursue collaborative research projects on cultural landscape and traditional cultural properties, conduct NAGPRA or Section 106 consultations, and develop agreement documents can find working with multiple parties on potentially contentious issues to be a challenge. Effective communication and conflict management tools are useful in establishing and maintaining relationships with Indian tribes, descent communities, state and federal agency officials, and other participants in the process. Alternative dispute resolution (ADR) techniques are common approaches for settling potential lawsuits outside of the court system. Moreover, they have a utility and role in clarifying interests and ensuring better communication so as to avoid having conflicts rise to the level of court-bound disputes. For this reason, ADR techniques are applicable in contexts of cultural resource compliance where the parties involved may have diverse interests, and where relationships between entities, if not individuals, are long-term. This poster session introduces basic concepts and techniques of ADR. It provides examples of how facilitation, negotiation, mediation, and other ADR approaches can be applied effectively in cultural resource settings. By reframing standard approaches to cultural resource compliance using the ADR tools, archaeologists can better manage potential conflicts and develop satisfactory long-term relationships with other parties.

Graham, Lain (New South Associates Inc. and Georgia State University) and Hugh B. Matternes

Unwelcome Pay for a Hard Day’s Work: Osteoarthritis in Two African-American Cemeteries on the Outskirts of Savannah, Georgia

The relocation of two African-American cemeteries on Hunter Army Airfield in Chatham County, Georgia, enabled New South Associates, Inc. to examine human remains for evidence of joint deterioration as a means of assessing quality of life. 9CH1168 (Area 1) contained 40 individuals, while 9CH875 (Area 2)
yielded 346 interments. Emancipated local and refugee communities deposited both cemeteries in the mid-late 19th and early 20th centuries. All remains were sexed and aged using standard osteological methods, and the severity of osteoarthritic changes were scored using a three-point ranking system. The age-at-death ranges were divided into three age groups, and comparisons were made between sex, age, and severity of skeletal response. Statistical analysis was used to identify patterns in the osteoarthritis data. A t-test and a liner regression were used to assess between sex differences, which verified the anticipated correlation between advancing age and severity of osteoarthritis. The Area 1 cemetery population represents a local community, which differed in overall health and socioeconomic status when contrasted with Area 2. This dichotomy warrants further examination of differences between cemeteries as it relates to osteoarthritis and degenerative joint disease to see if there are significant differences when contrasting a local and refugee populations.

[336] Conceptualizing Communities of Weavers and Group Identity through the Analysis of Fragmented Andean Textiles

Excavations from 2011-2013 at the highland site of Hualcayán in the Callejón de Huaylas valley, Perú have revealed an abundance of surprisingly well-preserved textiles and cordage. Despite preservation, these materials come from looted tomb contexts, dating to the Early Intermediate Period and the Middle Horizon (circa AD1-1000). The long-term mortuary use and architectural transformation of these ossuaries in the ancient past have contributed to the fragmentation and decay of fiber-perishable materials. Through technical attribute analysis using high-powered microscopy, we examine the hypothesis that single communities of weavers tend to produce relatively homogenous textiles because of a uniformity of practice (standardization in technical or stylistic attributes) in production. We argue that the sharing of technical knowledge and practices forges a collective identity and set of values. Despite the sample’s looted context, this study demonstrates that (1) fragmented textiles have the potential to infer the presence of discrete communities of practice in the ancient past, and (2) careful technical analysis of looted artifacts can reconstruct some of the contextual information that contemporary grave robbers destroyed.

Grave, Alfonso (INAH Sinaloa)

[339] No Todo lo que Reluce es la Cerámica Aztatlán: Arqueología del Sur de Sinaloa

Fue en el sur de Sinaloa, en 1930, donde por vez primera se reconoció lo que se denominó cerámica Aztatlán. Sin embargo, la arqueología de la región no se limita únicamente a este rasgo. En los últimos años he desarrollado trabajos de investigación en las cuencas de los ríos Presidio y Baluarte, así como en las marismas de Escuinapa. Con los datos obtenidos he logrado establecer que la ocupación se remonta a los inicios de nuestra era y que la complejidad social inicia varios siglos antes del surgimiento del complejo cerámico Aztatlán, lo cual se manifiesta tanto en la construcción de estructuras monumentales, cuyo patrón arquitectónico se mantiene a lo largo de los siglos, como en la explotación intensiva de los recursos del estero, cuya importancia fue tal, que incluso en el ambiente hostil de la marisma se erigieron edificios ceremoniales destinados a la realización de rituales propiciatorios de una buena temporada en la pesca y las salinas.

Gravel-Miguel, Claudine (Arizona State University)

[299] The Pebbles of Arene Candide

Bernabo Brea and Cardini’s 1940-42 excavation of the Grotta delle Arene Candide (Italy) uncovered a Mesolithic necropolis of about 20 skeletons. Most of the individuals were interred with different types of grave goods, including assortments of rounded flat pebbles. The presence of these pebbles in a karstic environment 90m above modern sea level shows that these artifacts were deliberately selected and transported to the cave to be discarded in a mortuary context. Those pebbles have never been studied in details and thus, their use is still unclear. Through a microscopic study of 30 pebbles found in the 2009-2011 excavations of the Arene Candide’s Epigravettian layers, I address this question. The results of the analysis show that the majority of the pebbles – which were most likely collected from nearby beaches – were used in conjunction with ochre. The position and the extent of ochre traces vary by pebble but suggest the presence of ochre appliers and some grinders, which may be linked to the burial process
itself, as most skeletons were covered in ochre. This study provides a base against which I can study in
detail the 1942 assemblage as well as similar artifacts found in other Italian Epigravettian burials.

Graves, William (Statistical Research, Inc.) and Eric Klucas (Statistical Research, Inc.)

Communalism, Household, and Power in the Pre-Classic Tucson Basin
In this paper, we explore potential variability in power and inequality among households and communities
in the Pre-Classic period Tucson Basin. We examine variability in household storage capacity, the
communal consumption activities, and access to social and economic relationships with the Phoenix
Basin, to identify variability in control over the means of production, the social scale of consumption, and
access to long-distance materials and ideas. Throughout the Pre-Classic period, a seemingly paradoxical
relationship between communalism and the rise of inequality developed among the Tucson Basin
Hohokam as households were able to acquire power differentially and social inequality became
increasingly entrenched.

String Figures and Dominant Cords: Tying Ethnoarchaeological Views of the Crucial Roles of
Hunter-Gatherer Fiber Use Together to Explore Patterns of Technological Organization and
Economy
Compared with other classes of archaeological remains, methods for studying the roles of technologies
constructed from organic materials are underdeveloped. Significant recent advances in the identification
of plant remains and DNA have expanded the opportunities for detecting their presence in archaeological
deposits. However, the greater archaeological visibility of durable materials, such as lithics or ceramics, is
still equated with their assumed past technological or behavioral importance. Ethnographic studies
demonstrate that the vast majority of traditional technologies either rely on organic materials for the
majority of their components, or are entirely made from such materials. This study examines the ways
that plant raw materials are collected, processed, manufactured, and used in longitudinal
ethnoarchaeological research with savanna hunter-gatherers of Venezuela. Special emphasis is placed
on the critical roles that string, cord, and basketry play in the technological strategies of Pumé foraging.
This study identifies the dominant role of organic technology and explores links with other classes of
more archaeologically visible artifacts to expand understanding of the use dynamics of these
underappreciated technologies. Comparisons with other ethnoarchaeological data examine potential
distinctions between foraging, horticultural, or agriculturally based economies and their technological
organization.

Seeing What’s Happening on the Fringe: Exploring the Visual Representation of Cross-Cultural
Interaction
In order to more clearly elucidate the processes that occur in the context of colonization, frontiers, and
ancient borderlands we have developed a model of cross-cultural interaction that visually represents
simultaneous interactions by numerous participants visually. Our model explores the various ways in
which people interact and what motivates their participation in cultural exchanges or what they reject. This
paper serves as an introduction to the session and its purpose of testing the visual interaction model. In it
we provide a basic introduction of this model and its theoretical origins and review the changes we have
made since its inception. Finally a brief introduction of the case studies in this symposium serves to
showcase the wide range of applicability of this model.

Museum Resources for North African Archaeology: The Collections of the Logan Museum of
Anthropology
Museum collections supply important research resources for Africanist archaeologists. As an example,
Beloit College’s Logan Museum of Anthropology houses about 120,000 objects from 200 site locations in
Algeria and other parts of North Africa. Most of this material derives from the museum’s surveys and
excavations from 1925 through 1930. Notable collections include Middle Stone Age and Epipaleolithic material. Much of the material was catalogued and published in the 1930s, but relatively little analysis has been conducted since then despite advances in method and theory. Documentation and provenience data are good for most collections and are being refined through archival research. The collections retain significant research value, especially for work on MSA and Capsian cultures and on topics such as lithic technology and mammalian, molluscan, and avian (ostrich) resource use. The collections are also of historical value in terms of the legacy of early American involvement in African archaeology.

Greene, Alan (University of Chicago), Charles Hartley (University of Chicago) and Paula Doumani (Washington University in St. Louis)
Since 2005, a consortium of Eurasian archaeologists from various North American universities has been working in concert with material scientists at Argonne National Laboratory as The Making of Ancient Eurasia (MAE) Project, to collect instrumental data and develop new analytical techniques that speak directly to the research needs of our particular archaeological community. From a cultural and historical perspective the vastness of Eurasian archaeology often prevents the development of pan-regional research questions and collaborations. Yet our project demonstrates one clear intersection may be found in an investigative framework that can comprehensively develop assemblage-based knowledge “from the ground up.” In exploring and analyzing so-called virgin territories and unexamined assemblages, Eurasian archaeologists possess a particular need to parse robust samples of diverse materials. The MAE Project, studying radically different sociohistorical contexts from the Caucasus to China’s central plain, has spent nine years developing a cohort of instrumental techniques for the non-destructive and high frequency analysis of large archaeological assemblages. Our shared goal to deconstruct complexes, collections, and technologies investigated previously under dominantly evolutionary, functionalist, and culture-historical paradigms has propelled a rapid diversification of archaeological perspectives on production regimes and cultural formations that were previously understood as undifferentiated and homogeneous.

Greene, Lance (Georgia Southern University) and Matthew Luke (Georgia Southern University)
[221] The Whole Shebang: The Use of LiDAR Technology to Identify and Record Union Prisoners’ Huts at the Confederate POW site of Camp Lawton
The Confederacy constructed a massive POW facility, Camp Lawton, in the summer of 1864 to relieve the horrendous conditions at Andersonville. Excavations at Camp Lawton by archaeologists from Georgia Southern University have uncovered pit features representing semi-subterranean huts, called shebangs, dug by the prisoners held there. Recently, GSU archaeologists have incorporated LiDAR scanning as one method to identify and record these huts. High-resolution scans are used to create digital elevation models, which aid in locating subsurface features. Shebang features exposed in excavation blocks are recorded using scan data, including standard point clouds, intensity values, and photographic imagery.

Greenlee, Diana (U of Louisiana - Monroe)
[165] Measuring Earthwork Stability Under Changing Vegetation Cover at Poverty Point
Erosion poses the greatest threat to earthwork preservation. Guidelines for landscape management of earthworks advise that grassy covers are the most effective for protecting earthworks against erosion, but woods can also provide adequate cover. Woods provide the most protection when they are composed of small trees with a good duff layer underneath. Although earthworks can be stable under either vegetative regime, it is considered risky to switch between them.

In August 2009, the Louisiana Office of State Parks began removing trees from the earthen mounds at Poverty Point in order to establish a grass cover. It was done for reasons of preservation (falling trees threatened the integrity of the mounds) and a more authentic visitor experience (the mounds were treeless when they were built roughly 3400 years ago). This presented an opportunity to use techniques of dendrogeomorphology (tree-ring dating of surface processes) to study historic rates of erosion under
wooded cover. Erosion during the shift in vegetative cover from trees to grass was monitored using the stumps as control points. Soil loss rates under these different vegetation regimes are compared with each other and with estimated damage had the trees not been removed.

Greenwald, Alexandra and Jelmer Eerkens (University of California, Davis) [163] Stable Isotope Measures of Age at Weaning and Early Childhood Diet as a Proxy for Parental Investment Strategies During the Medieval Climatic Anomaly in Central California

Human behavioral ecology predicts that individuals alter reproductive strategies in response to environmental conditions. Individuals are predicted to invest less in each offspring during periods of environmental stress to maximize their number of offspring. Conversely, individuals will invest more resources in fewer offspring during periods of environmental stability. We test this by estimating measures of parental investment – weaning age and early childhood dietary quality - from serial samples of dentinal collagen. 515N, 513C, and C:N ratios were generated for 35 individuals from the San Francisco Bay Area archaeological site CA-ALA-554, which was occupied during the Medieval Climatic Anomaly (MCA). The MCA (1200-600 B.P.) was a high-stress period of environmental instability in Central California. These results are contrasted against 40 individuals from four different sites in the same region that pre- and post-date the MCA – when environmental stress was less. Our findings confirm that parental investment in offspring was lower during the high-stress Medieval Climatic Anomaly in Central California, and provide support for predictions from life history theory.

Greer, John (Greer Archaeology) and Mavis Greer (Greer Services, Archaeological Consulting) [156] Masks in American Rock Art

Masks occur in rock art throughout the world as part of a general propensity for humans to portray human and humanoid faces in various forms, contexts, purposes, and meanings. Our small sample from the New World concentrates on the Northwestern Plains, American Southwest, and extended Caribbean area. Rock art masks appear to be comparable in presentation and use to faces in other media such as actual masks on dancers or produced for other purposes, as documented among the Hopi and cultures of northwestern Mexico and northern South America. Drawings of faces onto other media (e.g., walls, plaques, ceramics, sand, trees) have similar characteristics of private, public, and instructional art, as do actual painted faces as part of physical body decoration. Masks may be personal signatures or referents to deities, supernatural beings, or generalized concepts. Rock art masks, as with other face portrayals, mostly appear to be ritual related but also may refer to clan affiliation, specific social society membership, social control, history, and beliefs related to agriculture.

Greer, Mavis [156] see Greer, John

Greer, Mavis (Greer Services) and John Greer (Greer Services, Archaeological Consulting) [248] Fingerlines in Central Montana Rock Art Compared with European Finger Flutings

Painted fingerlines now are receiving attention in central Montana as a distinctive rock art element and are differentiated from tally marks (rows of short lines of generally equal length) in size, grouping, and meaning, although the general method of application is the same. Fingerlines are made with red paint, often occur in groups of three, and are usually at least 30 cm long. These are intentional element groupings and are separate from hand-cleaning smears. They are occasionally similar to straight finger flutings in deep caves in Europe, Australia, and elsewhere, and French research has shown the potential to identify individuals, approximate age, gender, and number of people participating in specific groupings. We examine how the North American and European marks compare and what we can learn from the extensive research in other countries to better understand the images in North America.

Gregoricka, Lesley (University of South Alabama) [67] Regional Mobility in the Land of Magan: Strontium and Oxygen Isotope Analysis at the Al Khubayb Necropolis, Oman

Radiogenic strontium and stable oxygen isotope analyses permit considerable insight into patterns of migration and residential mobility in archaeological populations. In the Bronze Age of southeastern Arabia, questions regarding the nature of human mobility are essential to elucidating the shift from nomadic pastoralists building small circular cairns in the Hafit period (ca. 3100-2700 B.C.) to sedentary...
communities constructing large collective tombs in the Umm an-Nar (ca. 2700-2000 B.C.). As no settlements have been discovered in association with tombs from the early third millennium B.C., this transition remains a poorly understood but pivotal time in Arabian prehistory. Recent excavations at the Al Khubayb Necropolis in the desert interior of Oman have revealed a number of tombs dating to this "Transitional" period, and individuals interred within these funerary structures present an exciting new means of assessing mobility in the region. The hypothesis that local communities engaged in a semi-nomadic lifestyle was tested using dental enamel from individuals interred in three large Transitional tombs. Instead, both $^87\text{Sr}/^86\text{Sr}$ (0.708531±0.000078, 1o) and $\delta^{18}\text{O}$ (-1.4 ± 0.3, 1o) ratios exhibit little variability, indicating that this Transitional period was a time of declining mobility coinciding with an increasingly complex social landscape in the Oman Peninsula.

**Soil Drainage, Roads, and Predictive Modeling: Mapping Site Probability on the North Carolina Coast**

Predictive modeling of site probability based primarily on soil drainage characteristics was tested on a large CRM project on the North Carolina Coast. This research explored the utility of soil drainage as a site predictor when compared with other factors such as site age, proximity to roads, and elevation. Because well drained soils mirrored the locations of roads, towns, and farms, the model appears to work in certain cases. However, especially for recent historic sites, soil drainage is shown to be a poor predictor of site location.

**Backyard Investigations along the Crabgrass Frontier: An Archaeological Exploration of Suburbia**

American suburbanization began during the early 19th century, and since then, suburbia has been characterized as a land bound by dreams, contempt, and myth. The popular image portrays suburbia as a homogenous setting; however, suburbanization is really marked by a mixed emphasis on residential, commercial, and industrial development in addition to a diverse set of competing social and economic conditions. Geographers and historians explore some of these issues through the spatial layout of suburbs as revealed by the changing character of built environments, but few researchers have examined the lives and motives of individuals residing in early suburbs. Can archaeology remedy this situation and contribute to a greater understanding about suburbanization in America? This is one goal of the DePaul University Urban Historical Archaeology Field School, which is excavating residential yards in the Village of Maywood, Illinois. Maywood is an early Chicago suburb dating to the late 1860s, and Village yards have yielded data that inform about sanitary practices, dietary habits, children’s interests, and household activities, in addition to other insights, all of which are supplemented by documentary sources. Far from being a sterile research topic, suburbia offers archaeologists a fertile field of inquiry occupying the historical rural-urban fringe.

**An Evaluation of OSL Dating of Ceramic Sherds from the Nebraska Sand Hills, USA**

We report on a program of optically stimulated luminescence (OSL) dating of ceramic sherds and its potential for helping us understand past human behavior in the Sand Hills of Nebraska during the peri-Medieval Climatic Anomaly (AD 900-1300), when warmer and drier conditions prevailed here. Ceramic sherds derived from site collections maintained by the Nebraska State Historical Society were sampled. Sediment samples from these same sites and archaeological contexts provide the dose rate for analysis. Here, we discuss the preliminary results of this analysis and the potential for application in other regions.

Grier, Colin (Washington State University)
Actor Networks and Coastal Landforms in Precontact Coast Salish History: Formulating a New Approach to Some Key Issues in Northwest Coast Archaeology

Following a long engagement with unilinear and evolutionary notions of complexity, Northwest Coast scholars have been recently pursuing more historicized approaches to conceptualizing precontact lifeways. Despite this shift, few explicit statements have emerged that outline how we should now tackle critical issues such as the emergence of Northwest Coast settled village life, social stratification, and control over resources—enduring anthropological problems that transcend theoretical predilections. Here, I outline how a theory of Actor Networks, which posits human and non-human actors existing in complex relationships, can be employed for this goal. Drawing on data gained from coastal spit locations in the southern Gulf Islands of British Columbia, I focus on explicating the relationship between the construction of these landforms, the development of control over resources, and broader social inequalities. Positing both human and non-human actors in such processes emphasizes how natural and built environments recursively evolve and change over time, providing a framework for new practices and a vehicle for social transformation. As importantly, an Actor Network approach parallels animistic indigenous ontologies, offering an opportunity to develop indigenous-informed approaches without resorting to employing idealized ethnographic descriptions as models or explanations.

Griffin, Patrick

An Historian Looks at the Famine: Looking Backwards and Forward from the Vanishing Point

This paper will address the ways in which historians consider the Famine today: what it meant for Irish society; how it transformed migrations; and how it affected adaptation in America. The paper will put the Famine and its origins and legacies in the broad framework of links between Ireland and America in the Atlantic world and offer a new means of considering the event.

Griffin, Robert (University of Alabama, Huntsville), Nicholas Dunning (University of Cincinnati) and Thomas Sever (University of Alabama, Huntsville)

Measuring Ancient Human Influence on a River Drainage Using Multispectral Satellite Remote Sensing and a Channel Sinuosity Index

In the central Maya Lowlands, seasonal swamps (bajos) are a prominent landscape feature and are often found within short distances of ancient sites. The extent to which these depressions were used for agriculture remains unknown for most of the lowland region, however some isolated areas show evidence of stream channelization with ancient drained field agriculture being a likely culprit. This study focuses on the Ixcan Rio Basin of northeastern Guatemala, an area where both large and small Maya settlements developed around the margins of several large bajos including the expansive Bajo de Azucar. Initial visual inspection of high resolution multispectral satellite imagery (Quickbird, IKONOS) identified lengths of the Rio Azul which appeared less sinuous than what would be expected in the flat, homogenous environment of the surrounding bajo. We applied VNIR indicators of vegetation stress as proxies for drainage location and conducted feature extraction to isolate linear channels. We developed a Channel Sinuosity Index to quantify sinuosity and conducted a sensitivity analysis of segment length impacts on this sinuosity factor. We present the results here, focusing on the application of a sinuosity measure as a proxy for human influence on drainage channels.

Griffith, Cameron (University of Arkansas)

Cave Use, Ritual Apotheosis, and Tribute to the God(s) of the Ancient Maya Underworld

A recent exponential increase in cave research in the Mundo Maya over the past 30 years has yielded myriad data on the ancient use of caves. This paper presents recent analyses conducted on cave sites in the Macal River Valley of Belize, in order to elucidate spatial patterns and move towards a better understanding of a “grammar” of ancient Maya cave utilization. Some of the transforms affecting the assemblages in these cave sites are the result of natural processes, whereas others are due to formalized and structured intentions related to both functional activities and ritual practice.

Griffith, Anne (St. Charles Community College)

Field School at the Community College Level: A Happy Medium

One of the principles of modern archaeology is that we have a duty to the public to make our finds available. In the summer of 2013 an archaeology field school was conducted through St. Charles Community College outside of St. Louis, Missouri. This field school was structured differently than the traditional model as a way to make learning about archaeological methods more accessible to a wider range of people. Field schools like this one can be a great middle ground between single-occurrence
'archaeology days' and four- to six-week-long digs offered by many large universities. Many St. Charles students (and community college students in general) have children, are working nearly full-time, or have obligations beyond simple school work that make them unable to participate in multi-month-long projects. Additionally, community college field schools may be more financially feasible for those who have the desire but not necessarily the funds to work on digs throughout the US or abroad. With field schools being done on the community college level, we as archaeologists can reach even greater numbers of people and live up to a core tenet of contemporary archaeological practice.

Griffitts, Janet (SRI) [210] Get along Little Bunnies: A Possible Early Twentieth Century Rabbit Drive in Southern Arizona.
A single historical-period pit was discovered among the thousands of prehistoric features in the Luke Air Force Base Project, near Phoenix, Arizona, and that pit yielded over a thousand pieces of bone. Most are leporids or are from rabbit-sized taxa, including a minimum of fourteen cottontails and jackrabbits, interred with shotgun shells dating to the 1900s to 1920. Bones are well preserved, unburned, and many are intact. All leporid regions are represented, and portions were articulated at the time of excavation. Other pest species were found in the same pit.

Why are the rabbit carcasses so complete? Why were so many killed but not consumed? A look at early twentieth century interactions between humans and leporids offers a possible explanation. Jackrabbit drives are not only a part of Arizona's prehistory, but in the late nineteenth and the first third of the twentieth century, periodic localized peaks in leporid populations competed with cattle for forage and with farmers for their crops. The Arizona Territories offered bounties for rabbit ears and local ranchers and farmers organized rabbit drives in response, at times killing hundreds or thousands of leporids. This feature may provide evidence of a similar hunting episode.

Grillo, Katherine (University of Wisconsin - La Crosse) [186] "Nderit:" Typology, Archaeography, and the Implications of Pottery Use at Ceremonial Sites in the Turkana Basin
"Nderit Ware," a type of pottery famous in eastern Africa for its remarkably intricate basket-like bowls, is associated with evidence for the region's earliest pastoralism. This paper reviews the changing ways archaeologists have conceptualized "Nderit" pottery over the past eighty years, and discusses ways in which the archaeological process – the act of writing about archaeological evidence - has influenced the interpretation of Pastoral Neolithic sites throughout eastern Africa. The "Nderit" ware type was itself defined prior to the discovery of its early presence and fluorescence as a technology/artistic tradition in the Turkana Basin. New data from pillar sites west of Lake Turkana Lothagam North (GeJi9), Lothagam West (GeJi10), and Manemanya (GcJh5) suggest a much more variable and complex history of ceramic production and use than previously recognized. These findings carry important implications for reconstructing the cultural history and material lives of early herding groups moving within and beyond the Turkana Basin.

Grimm, Sonja (MONREPOS Archaeological Research Centre and Museum, RGZM) [278] Tomorrow Is Another Day: The Limits of Magdalenian Resilience in Lateglacial North-Western Europe
The onset of the Lateglacial Interstadial in north-western Europe is characterized by significant climatic and environmental changes. The transition from the Late Magdalenian to the Azilian occurred in this period. The Magdalenian reveals a highly generalist behavior adapted to a cold grass steppe environment with strong climatic fluctuations. In contrast, the Azilian shows a more regionally adapted behavior within a temperate forest environment. The transition between these complexes was analyzed based on assemblages from northern France, southern Belgium, and western Germany. According to the results, with minor adaptations the resilience of the generalist Magdalenian behavior coped easily with the initial
climatic and environmental changes. Moreover, the increase of resources during the continuing climatic
amelioration in this initial period caused a neglect of safeguarding strategies. As a result the buffering
mechanism failed to provide security during a period of climatic and environmental instability in the early
Lateglacial Interstadial and the Magdalenian way of life collapsed. However, with the following climatic
and environmental stabilization an established Azilian appeared abruptly based on the previous
Magdalenian adaptations. The process of change from Magdalenian to Azilian behavior in north-western
Europe can, therefore, be described as a phase-transition driven by climatic and environmental stability.

Groleau, Amy (Colgate University)

Conchopata’s Ceramic “Trophy” Heads: Breaking and Curating Anthropomorphic Vessels in A
Wari City

Studies of human head-taking in the Wari Empire, particularly the site of Conchopata, indicate an
enduring practice of raiding, captive taking, and eventual sacrifice that is linked to imperial expansion and
the buttressing of political authority. Iconography on ceremonial wares and remains from temple
complexes have illuminated such state-sponsored practices, but have left the involvement of the larger
community under-theorized as passive recipients of an ideological message of power and violence. New
research into domestic spaces at the site reveals a parallel practice of decapitation and curation of heads
from ceramic bodies that appears to predate and continue alongside the findings in the ceremonial
sectors. A systematic study of 44 unique architectural spaces identifies a complex interplay of civic and
domestic ritual practices in which anthropomorphic vessels and pieces of sacrificed pottery were
circulated through multiple contexts suggesting similarly dynamic social relationships in city religious and
political life.

Gronenborn, Detlef (Roemisch-Germanisches Zentralmuseum), Strien Hans-Christoph (Institut für

and Scholz Denis (Institute of Geosciences, Johannes-Gutenberg-University)

Dynamics of Neolithic Societies in Temperate Europe—A Pal eoclimatology-Informed Approach

Many archaeologists—at least in Europe—have been hesitant in accepting climate as one active
parameter in the formation processes of historic trajectories. This is certainly partly due to previous
oversimplifying hypotheses often formulated outside both anthropology and the historic disciplines.
We present current results of a project based at Roemisch-Germanisches Zentralmuseum/Johannes-
Gutenberg-University, Mainz, Germany, focusing on the dynamics of Neolithic societies of western
Temperate Europe (5500-3500 cal B.C.), in which paleoclimatic proxies and archaeological data are
confronted. Hypotheses are generated by going beyond simple event-oriented temporal correlations; we
try to understand social and economic dynamics over certain periods of time by analyzing the complex
interrelations between archaeological and paleoclimatological time series.

Grosch, Peregrine (College of Wooster) and P. Nick Kardulias (College of Wooster)

A Study of the Abandonment of Sites in Roman Britain

This study examines the collapse of the Western Roman Empire in the context of the abandonment of
Britain. Following Tainter's discussions of collapse and using a model based on Boak's interpretation of
the fall of the Western Roman Empire, this study seeks to explain the Roman abandonment of Britain by
examining the archaeological record at the sites of Calleva Atrebatum and Vindolanda. Calleva
Atrebatum features major indicators of the collapse of traditional city life such as a rubble filled gate, a
major junction filled with pits and the forum's basilica transformed into an industrial area with no
permanent residence, and little evidence of any occupation following the late Roman period. Vindolanda
exemplified Boak's notion of military threat and a shrinking Roman influence in the area, leading up to
complete abandonment of the fort. These lines of evidence provide a framework for examining the
collapse of the Roman Empire in the context of events in Britain.

Gross, Haley (Washington State University)

A Potential Method for Sourcing Shell Middens: Trace Element Ratios of Perna perna Mussels
from the Southern Coast of South Africa

Evidence of coastal exploitation is first found in the archaeological record ~164 kya at Pinnacle Point,
South Africa (Jerardino and Marean 2010). Though archaeologists have long understood the value of
shell middens, in the past, these analyses have addressed questions of temporal range of occupation,
group size, seasonality, and dietary contribution. Information is primarily derived from analyses of shell species, size, and frequency, though some investigations have used oxygen isotope analysis to understand seasonality and environmental conditions. Expanding upon recent studies in biology and marine ecology, I used laser ablation, inductively coupled plasma, mass-spectrometry (LA-ICP-MS) to analyze ‘elemental fingerprints’ (Becker 2004), or trace element ratios, found in the shells of Perna perna mussels from seven different locations along the southern coast of South Africa with a spatial distribution between 165 km to 5 km. This study aims to address not only the range of limitations of the method but also the possibility of employing this method for sourcing mussel shells found in the archaeological record. Identifying the source locations of shell middens could potentially open the door to new understandings of coastal foraging behavior and possibly even reveal insights into social networks and inter-group connections.

Grove, David (University of Florida)

[254] How Mesoamerican Culture History Has Cursed West Mexico

Since the 1950s some archaeologists have categorized the prehistory of non-Maya Mesoamerica into four periods: Olmec, Teotihuacan, Toltec, and Aztec. That simplistic but popular culture historical paradigm utilizes Central Mexican prehistory as a yardstick to measure cultural developments in other regions of Mesoamerica, including West Mexico. In addition, Paul Kirchhoff’s well-known list of defining traits for “Mesoamerica” is heavily laden with central Mexican attributes. Based on those culture classifications, certain regions of Mesoamerica were privileged, while others, such as West Mexico, were marginalized and virtually ignored. The legacy of the culture history approach still impacts Mesoamerica today. In fact, the question has frequently been raised, is West Mexico part of the Mesoamerican culture area? The region is sometimes excluded from Mesoamerica on maps and in textbooks, and most Mesoamericanists have little knowledge of the archaeology of West Mexico. This presentation reviews the negative impacts of culture history on West Mexico and discusses Formative Period archaeological research in West Mexico to demonstrate that the region was indeed part of Mesoamerica, yet its contributions continue to go unrecognized.

[343] Viable Soil Microorganism Trophic Group Composition and Density: Useful for Paleoclimatic Reconstruction and Relative Dating?

Paleosol microorganisms are capable of surviving in paleosols for many millennia by entering states of dormancy or exhibiting slowed metabolic processes. Surprisingly, microorganisms have only rarely been studied in archaeological contexts. Some scholars argue that contemporary microbial community composition in soils is retained after burial, continuing to reflect trophic group ratios at the time of soil formation. This presentation details the results of a research project with two main objectives: 1) to test a previously proposed microbial technique for paleoclimatic reconstruction implemented using paleosols located stratigraphically below kurgan burial mounds in Russia and 2) to present and evaluate a preliminary method for relative dating of paleosols using microbial densities throughout a vertical sample column. Soil microorganisms from Hell Gap Locality I, Wyoming, were cultured on three different solid media in order to calculate the community composition and density used to evaluate these techniques. Microbial trophic group composition did not yield paleoclimatic results that significantly correlate to prior reconstructions, but did significantly correlate to pH (which differed between media), indicating that pH might be acting as a confounding variable within this method. Microbial density, however, decreases with age, indicating that density could potentially be used as a relative dating technique.

[292] A Mechanism for Collection, Transport and Distribution of Maritime Resources into Mainland Markets in Chetumal and Corozal Bays
Leslie Shaw analyzed the faunal remains from the site of Ek Luum on Ambergris Caye, Belize. Observation of economic behavior of mainland fishermen camping on Ambergris Caye and selling in the Corozal market in 1985 serves to link analysis of maritime and island catchment zones with patterns of faunal remains from Cerros on the shore of Corozal Bay. Combined, the behavior of modern fishermen serves as an analogous mechanism that reflects a model of Classic period residents of Ambergris Caye providing both fresh and salted and dried fish to mainland markets.

[110] Residential and Public Architecture from the Perspective of Monte Viudo, Chachapoyas, Peru

In this paper, I critique the scholarly distinction between "vernacular" architecture and institutional, monumental, or elite architecture, using a case study from the settlement site of Monte Viudo in Peru’s northern highlands, which was built and occupied between A.D. 900 and 1450 by an ethnically Chachapoya community. The monumental character of Monte Viudo’s houses, their excellent preservation, and the unusual absence of public architecture in this built environment make it an especially fruitful setting in which to explore the social role of residential architecture. On the basis of these data, I argue that the archaeological tendency to isolate the study of residential and public architecture impoverishes our understanding of both phenomena by obstructing comparison of the construction practices, meanings, and social milieu out of which both come into being. In particular, I argue that anthropological scholarship of vernacular architecture has undervalued the role of human agency in the creation of house form, which has led to an overreliance on standard interpretive tropes such as structuralism, habitus, and "tradition." In order to counterbalance these tendencies, greater consideration of the construction process and the material features of residences is essential for approximating their role in a particular society.

[279] High Culture in Preclassic Mesoamerica: Sculpture, Ideology, and Identity

This paper explores sculpture and its role in the creation, visualization, and structure of Preclassic urbanism. It focuses in particular on the shifts in sculptural form and imagery during the transition from the Middle to the Late Preclassic period. To do so, it considers both monumental sculpture but also other figural imagery more generally, focusing especially on how representation of the human form – and consideration of where it appears, how it is articulated, and in what medium – provides a rich and nuanced view into how sculpture was wielded by elites to give physical form to notions of “high culture” in Preclassic Mesoamerica.

Waste management practices are a critical aspect of human sanitation and health yet can be difficult to ascertain from often scant and incomplete archaeological records. This poster presents a pilot project to determine the feasibility of detecting human control and disposal of fisheries waste at the 17thC. fishing settlement of Ferryland, Newfoundland, Canada, using stable isotope analyses of rat remains. Recent stable carbon and nitrogen isotope work on animal bone collagen identified local husbandry practices for omnivorous domesticates (pigs and dogs) based on fish offal from the adjacent fishery. New bone
collagen data presented here suggests that many rats (n=30) cohabiting the fishery did not have access to the fisheries refuse. These results indicate that while a certain amount of fish offal was allocated to omnivores domesticates, other fisheries refuse was likely disposed of away from the settlement. In the context of the historical record, suggesting that fisheries waste management practices at contemporaneous fisheries could be unsanitary, these findings have important implications. Moreover, these analyses show how a comparison of species with differing human-animal relationships (unwanted scavengers vs. provisioned livestock) can begin to unravel aspects of waste management regimes and the cultural ideas of sanitation that underlay them.

Investigating the Production Landscapes of Southern Andhra Pradesh

Excavations in South India have yielded significant numbers of iron and glass artifacts from a variety of contexts. These varied and prolific consumption patterns seem to indicate that these items played an important role in early South Indian societies. However, we know little about how and where these artifacts were produced, and especially what relationships, if any, there existed between these and other technologies. Here we present the results of the preliminary season of a project investigating the organization of various technologies – especially glass and iron production practices – in southern Andhra Pradesh, along the Swarnamukhi River Valley. Survey revealed a variety of sites, some with significant pyrotechnological evidence. The variation among and within these sites indicates a complex production landscape comprised of multiple technologies, including but not limited to iron and glass production, and highlights the fruitfulness of an explicit focus on identifying and documenting production evidence. The spatial patterning of production evidence allows us to begin identifying possible communities of craftworkers and the relationships between them. Future research will focus on further delineating the geographic and chronological patterning of production practices in order to better understand such inter-relationships.

Interpreting Ancestral Puebloan Settlement Patterns and Spatial Discontinuities Through the Use of Archaeological Predictive Modeling: An Example from the Northern Rio Puerco Basin in Northwestern New Mexico

Ancestral Puebloan settlement patterns in the Northern Rio Puerco Basin in northwestern New Mexico remain poorly understood despite extensive archaeological survey coverage throughout the region. In response to this, an archaeological predictive model is constructed that characterizes the relationship between Ancestral Puebloan site location and a number of independent environmental variables, including terrain roughness, proximity to water resources, and elevation. The results of this predictive model confirm the presence of a large spatial discontinuity in Ancestral Puebloan activity west of the immediate Rio Puerco Basin and suggest that resource availability or environmental conditions may have played a major role in settlement preference during the Pueblo III period. In addition to testing a geographically specific area, this study assesses the ability of the relatively new Random Forest modeling method in locating previously unrecorded Ancestral Puebloan sites in the wider Rio Puerco Basin. This study finds that the Random Forest method accurately identified over 29% of known Ancestral Puebloan sites in high potential zones comprising less than 3% of the total study area. By evaluating the results of this model against known sites, this model can be further refined and incorporated into future archaeological survey efforts in the region.

The Maya in Global Perspective

Roland Fletcher proposes that a "Low-Density, Agrarian-Based Urbanism" appeared world-wide during the first millennium A.D. That this form of polity appeared and disappeared in relative coincidence raises the question of background causes, a question that has to be answered before other issues such as causes of local change emanating from global climate and landscape engineering can be addressed. This paper attempts to identify a global context that might have encouraged their appearance. For comparison, recent analysis of the Maya Lowlands suggests that during the first millennium large cities were constructed in elevated landscapes away from abundant water to intercept trade routes. These
cities flourished so long as they could serve as entrepôts and sustain their vested interests. However, parallel to the interior cities, marine cities were also developing. They were slower to rise to power, apparently because it required a longer period to ramp up the skills of marine transport. When a downturn in climate destroyed the support system of the interior cities in the ninth century AD, the whole system collapsed, even the cities that were not particularly vulnerable to climate change. Does this scenario suggest anything about the other low density civilizations?

[167] Market Exchange and Household Provisioning in the Kiuic Polity during the Puuc Fluorescence
The fluorescence of the Puuc Region of the northwestern Yucatan during the Late Classic and Terminal Classic periods is best known through the impressive architectural building programs of its largest sites. The processes involved in this sociopolitical transformation have, however, only received limited attention. One key concern in reconstructions of this transformation is the mechanisms that integrated elite and non-elite members of Puuc polities. This is likewise an issue of concern in more general debates over the degree to which control of ancient Maya polities was centralized. This paper examines elite and non-elite household economic interaction during the Puuc fluorescence. Working from the perspective of "distributional approaches" to identifying exchange mechanisms (Hirth 1998), new models of the effects of non-market horizontal exchanges, vertical exchanges, and market exchanges on artifact variability were developed to identify household provisioning strategies. The results of these analyses suggest that market exchanges were utilized during both the Late Classic and Terminal Classic periods at Kiuic. The implications of this form of economic integration on broader political economic systems are discussed.

Gunter, Madeleine (College of William and Mary)

Siouan-speaking native communities across the Roanoke River Drainage in Virginia's southern Piedmont occupied a pivotal place on the seventeenth-century Southeastern geopolitical landscape. Between 1650 and 1676, the Siouan-speaking Occaneechi controlled European-Indian trade across southern Virginia. Acting as middlemen, they funneled deerskins from their western trading partners—the Sara—to English colonists in the East. On the periphery of Occaneechi-controlled fur trading networks, the Sara were free to selectively engage in, and avoid, the eastern deerskin trade. Drawing on material evidence from six contact-period sites in the Dan River Basin (the farthest western boundary of the Roanoke River Drainage), this paper examines and models the complex borderland processes that played out across the western Piedmont, with the goal of understanding how native communities on the "Siouan frontier" engaged in, and resisted, emerging deerskin trading economies during the seventeenth century. These analyses serve as a case study for investigating both the direct and indirect nature of colonial encounters at a regional scale.

[103] Sexing Commingled Remains to Evaluate Mortuary Organization: A Case Study from South-Central Peru
Sexing human remains is an integral part of evaluating demographic profiles and community structure among ancient and modern human populations. While there are fairly solid ranges for sexing the humeral and femoral head among modern populations, no such ranges exists for modern or prehistoric populations in Andean South America despite the plethora of ancient skeletal material within this region. This study attempts to address this lacuna through a study of 58 femurs and 71 humeri from commingled burial contexts from late prehispanic highland Peru (ca. A.D. 1000 - 1400). Metrics were employed to establish a preliminary range of humeral and femoral diameter lengths; discriminate function analysis was then used to determine the probable sex of the skeletal element. In this case, results suggest commingled burials in the highland Andes were likely structured by kinship, rather than sex.

[4] Ceramic Styles and Regional Interaction in the Savê Hills, Bénin
This study presents the first systematic description of ceramic artifacts from Late Iron Age sites in the Savè Hills area of Bénin, West Africa. Formal and stylistic features of the ceramics are used to delineate cultural historical phases. This study assumes that the movement of ceramics through Save Hills communities reflects regional interaction systems, and as such the distribution of ceramic types can be considered as an indicator of regional processes of migration, sociopolitical development, and trade. Intense warfare during the 19th century is considered as a potential catalyst for change in ceramic form and style.

[255] Does Raw Material Influence Bipolar Flake Morphology? An Experimental Examination of Quartz vs. Basalt

Lithic raw material differences are widely assumed to be a determining factor of flaked stone tool morphology, but this assumption remains largely untested. Two different sets of toolstone properties are thought to influence lithic artifact form. The first set is internal, i.e. the mechanical flaking properties. The second set is external, namely the form (size, shape, surface regularity, and presence of cortex) of the initial nodule, block, or blank from which the flakes are struck. In this paper we examine the effect of two different raw materials (quartz and basalt) on the morphology of experimentally produced bipolar flakes. Our results speak to hominin toolstone selection during the Pleistocene and contribute to wider debates about the relative influence of raw materials on stone tool morphology.

[284] A Balancing Act: Energetic Yield Objectives and Non-Food Resources during the Early Holocene on Santa Cruz Island

Santa Cruz Island is a varied landscape that harbors not only marine and coastal environments but also diverse terrestrial environments. Faced with a choice of these habitats, hunter-gatherers should occupy environments highly ranked with regard to food resource productivity, beginning with the environments that involve the least effort and least risk in acquiring sufficient resources. Within the environmental context of Santa Cruz Island, the abundant coastal and marine habitats that surround the island provided the abundant, clustered resources necessary for high-return forging. While these marine resources are integral in settlement decisions, hunter-gatherers would also be expected to balance energetic yield objectives and the need for non-food resources such as chert, and less abundant or seasonal resources such as plants or freshwater. Choice of habitation locale and the degree of mobility must, therefore, take into account the availability of both the key food and non-food resources needed for island survival. Research into the Early Holocene on Santa Cruz Island shows this consideration of abundant and less abundant resources and how this balance affects movement across the landscape.

[315] Early Coastal Migration Routes In the Pacific Northwest: A Case Study in Predictive Geospatial Analysis

Some of the oldest and most heated debates in archaeology center on the route and method of the arrival of the very first individuals in the New World. In this poster, I present a series predictive geospatial analysis techniques and test them against a case study that proposes routes of initial migration by Paleo-Indian peoples out of Asia along the coast of British Columbia into the new world. By quantitatively analyzing factors of topography, bathymetry, and the archaeological record at established Paleo-Indian sites using Geographic Information System (GIS) programs, it is possible to predict hypothetical routes across the landscape that existed ~13,000 years ago. I implement methodologies and techniques which identify areas that may contain archaeological material which clarifies to what extent and at what scale coastal migration was practiced. These methodologies combine elements of predictive modeling, least cost path analysis, and topographic analysis to look at this issue in new ways. The results of this case study demonstrate the usefulness and feasibility of these techniques in revealing patterns and findings.
which would not be apparent through traditional methods, highlighting the power and place of modern GIS analysis in archaeology.

[278] Developing a Method for Assessing the Skillfulness and Practice Time of Upper Paleolithic Artists
Archaeologists have tended to approach Upper Paleolithic art in the same way that art modern art is approached, with a focus on meaning. While this approach has yielded interesting results, its dominance has led to the neglect of another important aspect of art—the skill required to produce it. Research on the acquisition of skill suggests that an individual's level of skill in a given activity is primarily determined by the number of hours they have practiced that activity. With this in mind, we developed an experimental approach for the evaluation of skill in representative drawing, a common form of Upper Paleolithic art. First, we developed a set of criteria that can be used to evaluate drawing skill. Then, we asked 30 subjects with varying amounts of experience to produce drawings and provide an estimate of their hours of practice. Next, the subjects' drawings were scored with the evaluation criteria. Lastly, we regressed the scores for the drawings on hours of practice. We found a strong, significant relationship between drawing skill and number of hours of practice. Thus, we now have a tool with which to infer the skillfulness and practice time of Upper Paleolithic artists.

[69] Archaeological Research Contributions to the Study of Early Human Occupations in the Pampean Region of Argentina: Progress and New Directions
The Pampean region of Argentina has been a key area for the debate of early peopling of South America since the XIX Century. Nevertheless, systematic investigations started at the beginning of the 1980s. Since then, several sites have been excavated leading to the discussion of different issues that are part of the current research agenda of the peopling of the Americas. The aim of this presentation is to analyze how the archaeology of early hunter-gatherers of the region contributed to the following topics: a) paleoenvironmental and paleoclimatic reconstructions; b) timing and mode of the peopling process, c) lithic raw material procurement, technological strategies and the development of social networks, d) subsistence patterns, extinctions and survival of Pleistocene faunas in the Early Holocene, e) early human remains, chronology and diet , f) hunter-gatherer strategies developed for dealing with periods of stress of critical resources (e.g., water), g) landscapes modifications induced by human activities during the late Pleistocene-Early Holocene. Undoubtedly, abundant information was generated from the archaeological projects conducted in the Pampean region during the last 15 years, which positively impacted the advance of the knowledge of the early human occupations of the Southern Cone of South America.

Gutierrez, Gerardo (University of Colorado at Boulder, Department of Anthropology)

[83] Spatial Structure and Genealogical Interactions of the Complex Yuhuitayu of Tlapa-Tlachinollan of Mixteca Guerrero
This paper focuses on the ethnohistorical and archaeological formation of a complex Mixtec-Tlapanec-Nahua political system in southern Mesoamerica between the 14th and 16th centuries. Here, I will analyze how genealogical claims and key marriage alliances between ruling linages shaped the political development of the largest yuhuitayu/kubaa/altepelt of Eastern Guerrero. Further, I discuss how these arrangements were imprinted on settlement patterns and landscapes in the so-called La Montaña and Costa Chica regions of the state of Guerrero, Mexico.

[6] Residential Mobility, Site-Size Variation, and Archaic Foragers of the Altiplano

Agent-based models (ABMs) are used to predict archaeological site-size variation that emerges from foraging-radius models (FRMs) of hunter-gatherer residential mobility (sensu Binford 1982 and Kelly 1995). In the Lake Titicaca Basin, Peru, environmental parameters are consistent with those of FRMs. However, the ABMs demonstrate that FRMs as currently formulated cannot account for size variation among Late Archaic Period (7000-5000 cal. B.P.) hunter-gatherer sites in the region. I propose an alternative model that draws key behavioral insights from hunter-gatherer ethnography and statistical mechanics. The model posits that residential mobility is predicated upon the trade-off between subsistence and social interests. At each time-step in the agent-based implementation of the model, a given residential unit either (1) pursues social interests by moving to the residential location of another residential group with probability p or (2) pursues subsistence interests by moving to a novel location on the landscape with a probability of p-1. The model is empirically verifiable. Modeled settlement-size distributions are found to be statistically consistent with observations in the Titicaca Basin suggesting that this simple behavioral model holds explanatory potential.

Haas, Katherine (University of Pittsburgh)

The Early/Middle Bronze Age cemetery at Ostojicevo, northeast Serbia, represents a large undocumented sample of Maros-style burials (n = 285). The Bronze Age Maros Culture (2600-1500 B.C.E.), located between the Tisza, Maros, and Aranca Rivers in the southeastern Great Hungarian Plain, is defined by common mortuary practices and ceramic styles. Here, I compare mortality profiles between Middle and Late Bronze Age burials at Ostojicevo with Middle Bronze Age burials 20 km to the northwest at Mokrin (n = 318). I demonstrate that while adult mortality profiles are identical at Mokrin and Ostojicevo, the latter site is distinguished by the presence of infants (< 3 years at death) buried in urns. Because adult mortality is identical at the two cemeteries, I conclude that the presence of infants at Ostojicevo is due to changes in social dynamics and perceptions of personhood rather than increased child mortality. Treatment of infants corresponds to broader social conventions governing mortuary practices. Bodies in urns were placed in a flexed position facing east, and aligned along a linear N-S or S-N axis according to gender. This inclusion of children < 3 years at death is unique for the prehistory of the region and provides general evidence for high child mortality.

Haas, Mallory (Cleveland State University) and Elizabeth Hoag (Cuyahoga Community College)
[152] Developing Archaeological Vernacular When Approaching Salvage in Community: Decommissioning Euclid Avenue Churches in Cleveland Ohio

The obstacle of resurrecting conservancy and archaeology into the severed dialogue can take longer than the physical time and length of the project. At The Center for Community Studies (CCS) we have begun to be a voice of reason within city planning and dismantlement of spaces, if of course the space must be demolished. Over the past 20 months we have been working with the city, the property buyers, which is The Cleveland Clinic, the local congregations and the dioceses of these churches to help mitigate the loss of information and provenance of artifacts, including architecture, stained glass windows and each churches time capsule. We have been working to ignite a set of principles utilizing a holistic perspective of planning within the interested community on future threatened sites, savings of property and/or in combination with potentially abandoned archaeology resources around Cleveland and her surrounding suburbs.

Habicht-Mauche, Judith (UC-Santa Cruz)
[202] Tijeras in the Ancestral Pueblo World: A Pottery Analysis Perspective
During the 1970s, Linda Cordell supervised three summer field schools at the site of Tijeras Pueblo (LA 581), a fourteenth century Ancestral Pueblo village site located in the central Rio Grande region of New Mexico. The material recovered from those excavations continues to provide archaeologists with a wealth of information about migration, community formation and inter-regional interaction in the late Precontact Southwest, themes that were central to Cordell’s scholarship and intellectual legacy. This paper presents results of current research on Tijeras pottery, with particular emphasis on the early glaze-painted wares from the site. Data generated through a variety of integrated analytical techniques, including attribute analysis and characterization studies using optical mineralogy, neutron activation analysis, and lead-isotope analysis are providing us with a complex picture of how Tijeras emerged as a unique, aggregated community and its relations with the broader fourteenth century Pueblo world.

Mobility, Food Diversity, and Climate Change: Prehistoric Cases from East and South Asia

This presentation examines problems of subsistence specialization and centralization, including intensive hunting-gathering and full-scale agriculture, in relation to the impacts of climate change. Previous studies tended to associate sedentism and large-scale agriculture with more “advanced” societies. However, archaeological studies from prehistoric Japan and northern South Asia indicate that mobility (including seasonal sedentism) associated with diverse subsistence strategies (including hunting-gathering and small-scale millet cultivation) may have been the key to understanding the growth and decline of prehistoric cultures. The role of climate change is emphasized as a constant and crucial variable in understanding long-term social change.

Hadden, Carla (University of Georgia) and Maran Little (University of Georgia) [216]

A Comparison of Cool- and Warm-Season Subsistence Practices on the Woodland Gulf Coast (USA)

Resource scheduling is a compromise among the social, economic, and political needs of the group, the availability and distribution of potential resources, and the perceived value and ease of procurement of the resources themselves. The seasonal aspects of resource use are fundamental to other significant human behaviors including ritual cycles, settlement patterns, and social and political organization. We investigate the seasonal aspects of resource scheduling at Plash Island, a Woodland-period site on Mobile Bay, Alabama (USA). Stable oxygen isotope analyses of mollusc valves and fish otoliths were used to estimate the seasons-of-deposition of several small, discrete pit features, presumed to be relatively rapid depositional events. Here we present the zooarchaeological data for just two of these features; one deposited during a cool season, the other deposited during a warm season. We compare the richness, diversity, and equitability of animal resources used in one locale during different seasons of the year. A similar suite of fishes, shellfishes, reptiles, and mammals are represented in both features, but their relative abundances differ.

Past Practices and Current Interpretations: A Case Analysis of Commingled Skeletal Remains at Neolithic Çatalhöyük

To date, bioarchaeological analyses of commingled skeletal remains have been less of a focus than studies of single primary inhumations. Commingled assemblages are traditionally viewed as being constructed through the occurrence of successive burial events or as a result of catastrophic episodes leading to multiple, simultaneous burials. These scenarios contribute to high levels of disarticulation, mixing, and fragmentation, and commingled assemblages are often considered to be of less utility for addressing population-level research questions than more well-preserved, articulated skeletal remains. In this paper, we use three-dimensional modeling techniques to document, analyze, and present two examples of commingled assemblages excavated in Building 52 at the Neolithic site of Çatalhöyük (9400-8000 y B.P.). We highlight variation in mortuary practices within adjacent burial platforms that has resulted in the creation of two very different commingled assemblages, one characterized by successive interments and the other by a single-event collective burial. Such variation reflects the deliberateness with which certain acts of commingling occurred and thus the past intent associated with the construction of particular burial assemblages. The burial events and sequences presented here are interpreted within the framework of building closure and abandonment, tying mortuary behaviors into other household and
community-level social practices at Neolithic Çatalhöyük.

Investigations at Burgas Ni Am Buddhist monastery in the Northern Gobi, Mongolia

The ruins of the Buddhist Monastery at Burgas Ni Am are located in Ikh Nart Nature Reserve in the desert steppe region of the Mongolian Gobi Desert. No information was available regarding how the monastery was destroyed or if it naturally deteriorated over time. A systematic test excavation was conducted during the 2013 summer field season. The goal of these test excavations was to ascertain if there is any subsurface physical evidence such as fire affected stone, charcoal, or ash in and around the structure to indicate how the monastery came to be in the ruined state it is today. The excavations were modeled on a Cultural Resource Management (CRM) industry design in order to maximize the data collection potential of a small team of people with limited time and limited resources. This goal was attained based on materials recovered from Shovel Test Pits, Surface Scrapes, and Controlled Excavation Units. The evidence supports the hypothesis that the monastery succumbed to the purges carried out against Buddhism and against Buddhist religious centers and their attendant monks in the early 20th century (1900-1939) by the burgeoning Communist Regime.

Use-Wear Analysis of Bone Awls from the Ozark Plateaus

This poster will present the results of a micro-wear study of bone and awls from various Archaic and Woodland period bluff shelter sites located in the Ozark Plateaus in Arkansas. The goal of this research is to understand the possible variation in the use of bone awls in relation to the types of basketry found in context at the sites. The use-wear will be compared and analyzed using GIS software to enhance image quality and to measure the periodicity of the striations. This research will look into how the size and shape of the awl is related to the intended use of the tool in a specific type of basketry production.

3D Virtual Curation of Archaeological Artifacts

This paper will discuss the transitional process from physical collections to a virtual 3D environment. 3D imaging is an innovative technology that enables users to preserve cultural remains to a virtual database which provide researchers remote access to collections not readily available. Due to the fragile nature of collections, the costs associated with housing assemblages, and international importing/exporting fees; a virtual database could be an invaluable asset to smaller institutions. Inadequate curation facilities can inadvertently cause damage to artifacts. The 3D models of archaeological remains can be utilized as teaching collections without damaging the “real” artifacts by constant handling. For the scope of this research two collections were digitally rendered; a faunal assemblage from northern California and Maya cultural remains from northwestern Belize.

“Footprints on the Sands of Time”: Constructing a History for the Ancient Maya Site of Ka’Kabish, Belize.

Archaeological knowledge is recognized as being a cumulative process; a process that both expands as well as changes our understanding of the past as new information is uncovered. Individual histories of ancient settlements also are produced by, and subject to, this process, thereby resulting in an ever emergent and increasing understanding of past cities and their inhabitants. With the addition of new discoveries made during the 2012 and 2013 summer field seasons we now have a fuller understanding of the occupation history of Ka’Kabish, an ancient Maya city in north-central Belize. These discoveries enhance our understanding of the chronological depth of the site as well as increase our understanding of the types of inter-regional exchange networks in which the inhabitants participated. Using these new discoveries, this paper will present a revised history of Ka’Kabish and tentatively locate this history into
Hale, John and Michael Coe (Department of Anthropology, Yale University)

Mapping a Submerged Preclassic Maya Site in Lake Atitlán, Guatemala

Recent underwater discoveries in Lake Atitlán, Guatemala, provided the opportunity to map a Maya archaeological site in its entirety. Rising lake levels covered the Late Preclassic site of Samabaj centuries ago, submerging stone altars, stelae, platforms and jetties dating from about 400 B.C.E. to 300 CE. Sidescan sonar helped delineate the ancient shorelines, revealing Samabaj as one of three islands that originated as volcanic littoral cones. Geological features determined the Maya site plan on Samabaj. Tuff deposits supported platforms for elite residences; pyroclastic ridges outlined a ready-made ceremonial plaza. Visitors were routed from a monumental jetty on the southeastern shore, through natural corridors in a ridge, to a platform mound near the island’s summit. Topographical connections to Maya creation myths may have enhanced Samabaj’s importance. Over a period of several millennia, volcanic activity first formed three littoral cones on a lava delta. Then rising lake levels created a small archipelago, and finally an isolated sacred island that gradually disappeared beneath the lake surface altogether. Future geological and archaeological research should establish a precise time-line for these transformations, and help us understand more fully the origins, functions and cultural connections of this small but important Maya site.

Remote Sensing Investigations of Maya Plazas in Western Belize

Monumental architecture has traditionally dominated the research agendas at Maya centers. A less conspicuous, but no less important, architectural feature is the plaza and activities associated with these remain poorly understood. One method for better understanding these features is remote sensing techniques such as magnetic gradiometer, electrical resistivity, conductivity, magnetic susceptibility, and ground penetrating radar (GPR). To evaluate these techniques, plazas were surveyed at five sites in western Belize: Cahal Pech, Xunantunich, Buenavista del Cayo, Pook’s Hill, and Plazuela Xubzulima. Geophysical results hint at features such as buried platforms and market areas. Results from plazas at monumental sites in other regions, including the southeastern United States, serve as an interesting comparison for those surveys.

Hall, John (Statistical Research Inc.)

Extramural Pit Classification: Form, Function, and Archaic period Land-use in the Western Phoenix Basin

Large-scale excavation of a 44-acre area within a larger site in the western Phoenix Basin of southern Arizona revealed close to 2,800 pit features. Observations of the size, shape, and thermal alteration of a sample (n= 1,379) of these pits allowed the authors to perform statistical examinations of pit spatial geometry in order to group similar pits, and to separate dissimilar pits. The results of these groupings were the establishment of 16 mutually exclusive categories of pit size, shape, and thermal involvement. These categories established a framework to examine pit function based on content and use. The results of this analysis show meaningful trends of spatial distribution across the excavated portion of the site, as well as chronologic groups within a larger cultural context. The examination of these extramural pit features provides insight into Archaic land-use and subsistence patterns, which are intimately tied to this lower-bajada landscape.

Exploring the taphonomic processes that impact the remains of undocumented border crossers in the Sonoran Desert of Arizona

Between 2000 and 2012, an average of 200 deceased border crossers per year have been recovered
along the Arizona and Mexico border. Despite this high volume of deaths, little is known about how bodies decompose in this environment or how animals impact corpses. Researchers with the Undocumented Migration Project have been conducting taphonomic experiments to better understand the rate of decomposition and the impact of scavengers in this environment. Using pig carcasses as proxies for human remains, we dressed these animals in clothes similar to those worn by migrants, placed personal effects in their pockets, and positioned them in contexts which replicate common features of migrant death sites (e.g., direct sunlight, shade). The decomposition process was documented through site visits, motion-sensitive cameras and GIS mapping, while skeletal preservation was investigated through faunal analysis following periods of animal scavenging. In this poster we present two seasons of taphonomic data and argue that scavengers can skeletonize and disarticulate skeletons faster than previous estimated. Moreover, the rapid destruction of bodies by environmental conditions, animals, and insects suggests that the current fatality count for the region grossly underestimates the actual number of people who have died while trying to cross the border.

Hall, Terrance and Ryan Collins (Brandeis University)

[326] Creating a Space for Public Archaeology: Spatiality in Yaxuna Urban Centers

As anthropologists, research often takes us to public places, but rarely does gained information leave our esoteric circles. The issue is not from a lack of public interest, but from a lack of understanding of the actual research, rather than its representations in the popular media. One method to promote public understanding in archaeology is through relating it to already familiar concepts and ideas. It is important to contextualize our research in the present rather than maintaining our binds to the past. One way such a goal may be achieved is through the explication of a strange concept, like an urban center, and making it familiar in the past and present. In this paper we focus on the modern Maya urban center of Yaxunah and its ancient counterpart. Despite several name changes in nearly 3000 years of occupation, the modern community, ‘founded’ in the 20th century, continues to undergo great change. Yet the town center, composed of administrative and religious centers, a mercantile district, and prominent family housing signifies a relationship to the past and a direction of present identity. The specifics allow this place to remain unique, but the urban center in this form is nearly ubiquitous.

[335] Archaeological Interpretation and the Use of Different Scales of Analysis from the Rio Parita Valley, Panama

A multi-scalar approach has played an important role in examining the archaeological record. By using different scales of analysis, archaeologists hope to obtain a more holistic and less-biased view of the past; in reality, however, it is difficult to achieve this goal. How can we best integrate different scales of analysis and be sure that the variation we see in archaeological patterning is not just the result of the different methodologies employed? To examine this concern, this paper focuses on a multi-scalar approach to investigating the rise of social complexity in the Rio Parita Valley, Panama. Specifically, I examine how interpretations from the systematic regional survey articulate with surface and sub-surface testing at the site of He-2. A comparison of archaeological interpretations from several different scales of analysis will be used to examine how different methodological approaches have influenced reconstructions of the past, and to offer suggestions for improvement.

Halligan, Jessi (University of Wisconsin La Crosse)

[114] Geoarchaeological Interpretations of Reported pre-Clovis Components in the Aucilla River, Florida

For nearly a century, collectors, archaeologists, and paleontologists have been recovering remnants of the terminal Pleistocene from the Aucilla River of northwestern Florida. Archaeological evidence has consisted largely of surface finds of diagnostic Paleoindian bifaces and osseous artifacts manufactured from extinct mammals, but formal excavations have revealed some artifacts buried in dateable sediments in potentially-intact contexts on sinkhole margins as well. Excavators reported a pre-Clovis component at Page-Ladson (8JE591), consisting of a handful of lithic artifacts and worked osseous material. A potential pre-Clovis component was also recorded at another submerged sinkhole site in the river channel, Sloth Hole (8JE121). Recent archaeological and geoarchaeological investigations at these and another sinkhole site, Wayne's Sink (8JE1508/8TA280) and the terrestrial areas adjacent to the three sites provide contextual interpretations of these components. Stratigraphic correlations between these sites inform upon paleoenvironments and site formation processes during the terminal Pleistocene and indicate the preservation potential for possible pre-Clovis components in the Aucilla Basin.

[12] Bone Resorption of the Distal Radius and Ulna: a Case Study from the Ray Site
The Ray site, a Middle Woodland cemetery located on a tributary of the Illinois River can be considered anomalous for a number of reasons. Primary among these is the absence of earthworks, as well as the presence of a remarkable range of anomalies and pathological conditions. Among the latter is a previously unreported resorptive syndrome located in the distal portion of the forearm. Extensive remodeling of the ulnar head along with focal resorption in the radius generally characterizes the pathology, which is detailed here and analyzed through an extensive differential diagnosis. Behavioral accommodations are considered, along with the relationship of this condition to others noted at the Ray site.

Halperin, Christina (Princeton University)

[110] Vernacular and Monumental Maya Architecture: Discourses and Changes during the Classic to Postclassic (ca. A.D. 800-1200) Transition
It is commonplace for archaeologists to note the similarities between modern and ancient commoner domestic architecture from Mesoamerica. Such comparisons often imply a relatively static perspective of vernacular architecture, which contrasts with a dynamic development of monumental and elite architecture over the course of Pre-Columbian history. Nevertheless, domestic architectural forms and the social, political, and economic lives of those who inhabited such structures were far from static. This paper examines the introduction of new vernacular architectural styles during the Classic-to-Postclassic-period transition in the Maya Lowlands and explores how ordinary people participated in a changing social, demographic, and political atmosphere amidst the collapse of royal dynasties across the region.

[16] The Ecology of Hunter-Gatherer Residential Mobility
Hunter-gatherer residential mobility varies along a spectrum from nomadic groups that move camp every few days and travel hundreds of kilometers a year, to those that reside in semi-permanent villages and are functionally sedentary. The factors that underlie this variation have long been of interest to anthropologists studying the behavioral ecology of foragers. Because hunter-gatherers harvest all resources they require for maintaining life, health, and well-being from wild plants and animals much of their basic ecology is fundamentally tied to the flows of energy and resources within the ecosystems in which they operate. Here, I show empirically, that variation in hunter-gatherer mobility is well-explained by a simple macroecological model of ecological production. To minimize the energy and time costs of mobility hunter-gatherer groups minimize travel distances between patches conditional on water availability. In warm wet ecosystems foragers travel the shortest distances and utilize the smallest patches. As ecosystems become cooler and drier travel distances and patch sizes increase exponentially at a rate predicted by theory. These results demonstrate that residential mobility is an adaptive behavioral response to the ecological and demographic environment, well-predicted by established ecological theory.

Stable Isotopes (δ13C, δ15N, and δ34S), Radiocarbon Dating, and the Chronology of Early Norse Settlers around Lake Myvatn, North-East Iceland

Radiocarbon (14C) forms the basis of the majority of archaeological chronologies developed from scientific dates, owing to the relative abundance of organic materials available for dating from most archaeological periods in the Holocene. While calibrated radiocarbon ages produce accurate estimates for the date of death for an organism that derives its carbon from terrestrial sources (i.e. charcoal, herbivores, etc.), the same is not true for organisms that derived some or all of their carbon from marine and freshwater sources. This paper explores using a multi-stable isotope approach to model marine and freshwater reservoir effects on human skeletal remains within a Bayesian statistical framework. We apply this to a dataset of 46 human skeletons excavated from an early Norse cemetery at Hofstadir, Lake Myvatn, north-east Iceland, in an effort to produce a more robust, accurate, and precise chronology for these earliest European settlers.

Initial Archaeological and Geophysical Results of the Spiro Landscape Archaeological Project

The Spiro mounds site in eastern Oklahoma, prominent from ca. A.D. 1200-1400, is best known for the remarkable objects and ritual tableau found within the Great Mortuary that have enhanced the study of Mississippian iconography and exchange. However, with few exceptions, research has focused on mounds and mound deposits. The Spiro Landscape Archaeological Project, begun in 2011, combines geophysics and targeted excavations to better understand both off-mound areas and the surrounding landscape. This paper presents the results of four weeks of geophysical survey and provides a preliminary report on recent excavations of geophysical anomalies along the lower terrace portion of the site.

Hammond, Norman (Department of Archaeology, Boston University)

Middle Preclassic Maya Economy at Cuello, Belize

A range of recovery methods including flotation, and analyses including macro- and micro-botanical identification of plants and stable-isotope assays of human and food-animal bones, have allowed reconstruction of local ecology and subsistence economy for the Middle Preclassic (1200-400 B.C.) Maya community at Cuello in northern Belize. Maize, root crops, and harvested tree products were complemented by domestic dogs and hunted deer and other forest species.

Networked Neighbors or Competing Villages? Using Bioarchaeological Data to Test Models of Regional Community Organization in the Ancient Southwest

Scholarly debates concerning hierarchical structure in ancient Southwest communities have proliferated in the literature since the late 1970s. Drawing from numerous data sets, researchers have postulated a range of competing models for Pueblo community organization. Recent works that integrate Hopi oral history and ethnographic analogy suggest convincingly that villages may not have clustered together as a homogenous community. Instead, a number of migrating clans interacting as autonomous smaller communities challenge the notion that pueblo clusters represent a distinct social grouping. Models of community organization suppose that hierarchy limits access to food resources and prestige. While supported by a variety of data, these models rarely integrate human skeletal remains. Information regarding community health and nutrition, which could be used to test hypotheses about the degree of food sharing and egalitarianism, has been overlooked. Building upon over 20 years of bioarchaeological research on Black Mesa, we present evidence of widespread nutritional stress and disease. Mortuary data, alongside osteological stress profiles that document homogeneity in hardship among and between communities, support models of egalitarian organization. These data suggest widespread inter-village food sharing. Such cooperation suggests that the ancestral Hopi of Black Mesa probably espoused a sense of regional community.

Hammond, Gail (University College London / Maya Research Program), Thomas Guderjan
Continuing Research at the Edge of the Alacranes Bajo, An Ancient Maya Landscape in Northwestern Belize.

We present continuing results of interdisciplinary efforts in determining the use and management of ancient Maya rural landscapes in northwestern Belize. Through our comprehensive data set combining archaeology, GIS, land survey and soil science, we provide a singular insight into the strategies used by the people that inhabited the sites of Nojol Nah and Tulix Mul on the periphery of the Maya world. Georeferenced maps - the results of intensive pedestrian survey - have been combined with a NASA digital elevation model as well as hydrological and soil data into a regional geodatabase, which includes the results of ongoing test units, and larger excavations. This poster focuses on work carried out between 2010 and 2013.

Handsman, Russell [152] see Kasper, Kimberly

Social Processes and Frontier Dynamics in the Late Prehistoric Eurasian Steppes

This presentation explores the utility of a model proposed by Green and Costion for comparative studies of inter-group interaction and dynamism. A diachronic case study will be discussed that focuses on Bronze and Iron Age developments (~1500-500 B.C.E.) in the north central Eurasian forest-steppe region (Southern Ural Mountains, Russian Federation) at the interface of the steppe and forest environmental zones. The Eurasian steppe region has been frequently discussed by scholars in terms of large scale interaction and integration in which World Systems Theory and core-periphery models have dominated. A detailed discussion of settlement evidence and ritual landscape appropriation are used in this presentation to examine cultural and social interaction and change in the context of models that stress increasing levels of migration and seasonal mobility by the first millennium B.C.E. New interdisciplinary field research from the Southern Urals region, including large scale pedestrian survey, environmental reconstruction, geophysical and geochemical surveys, and targeted excavation, are presented.

The Monterrey Shipwreck Project: Overview and Context

Lying at a depth of 4,300 feet off the coast of Texas in the Gulf of Mexico are the remains of three early 19th century shipwrecks, laden with a wide array of artifacts, from arms to tanned hides. Following discovery in 2011 and documentation in 2012, a privately-funded collaboration of federal, state, and academic institutions carried out a detailed mapping effort of the first shipwreck, Monterrey A, and recovered potentially diagnostic artifacts in 2013. This fieldwork also provided the opportunity to document two nearby shipwrecks never before investigated. The research took a multidisciplinary approach to answering questions about not only the shipwrecks themselves, but also a broader context of maritime activity in the Gulf region during a time of economic expansion and political transition, as well as site formation in the deep ocean environment. Additionally, the project incorporated a large public outreach component that allowed live participation throughout the fieldwork.

Hansen, Richard

Archaeological investigations in northern Guatemala have provided a strong record of the origins, dynamics, and collapse of social, political and economic complexity in the Preclassic periods of Maya civilization. Extensive isotope, pollen, and phytolith analyses have indicated that the economic engine of the marsh region of the Mirador Basin gave rise to cultural sophistication through abundant raw resources and agricultural exploitation. Sophisticated terrace systems provided rich agricultural resources that allowed population growth, ideological solidarity, and economic prosperity which fueled a rapid and dynamic cultural fluorescence during the Middle and Late Preclassic periods of Maya civilization (ca. 1000 B.C.-A.D. 150). This trajectory however, led to a conspicuous consumption of resources and blinded the societies to the abuses of labor, environment, and productivity by an increasingly top-heavy bureaucracy and elite. Stresses on societies apparently included, and were exacerbated by, excessive erosion, droughts and periods of dessication, and social upheavals which led to a posture of militaristic behavior indicative of predatory, symptomatic conflict.

[325] Soapstone Vessels in Viking Age and Early Medieval Norway: Producers and Consumers

Soapstone was an important outfield resource in Viking Age and medieval Norway. Some 200 quarries are surveyed, and 50 of these are found in the Hordaland region on the southwest-coast of the country. Vessels of soapstone were made both for local use and for wider distribution into the Norse area. How were the production and consumption of these goods organized? Did many small quarries deliver vessels to a wide range of consumers or did a few large quarries have a ‘monopoly’ on such services? How did one acquire a stone vessel? Did one cut it from one’s own local quarry, or did one buy it as a commodity on a market? Did this change over time? In this inter-disciplinary study, 149 stone vessels from urban and rural households in 12th century Bergen and Viking Age Hordaland, and their connection to 39 quarries in Hordaland have been studied. The vessels have been provenanced to known and unknown quarries through analyses of geochemical and archaeological data. The paper presents new understandings of how soapstone products moved from the hands of small and large scale producers to urban and rural consumers through local as well as superregional relations and networks.

[215] Archaeological Site Preservation Instruction: The Iraqi Institute for the Conservation of Antiquities and Heritage, University of Delaware

In the recent past archaeological sites in Iraq have suffered dramatic damage. This paper describes training efforts to prevent future damage and maintain archaeological sites through the new Archaeological Site Preservation Course (ASP) at the Iraqi Institute for the Conservation of Antiquities and Heritage in Erbil, Iraq. Through the University of Delaware's Academic Programs at the Iraqi Institute employees of the Iraqi State Board of Antiquities and Heritage and the Kurdistan Regional Government have participated in the course. The ASP focuses on strategies for identification, evaluation, prioritization, and stabilization of archaeological sites.

This paper details the success of the ASP’s two training courses and the future developments for the Archaeology Preservation Program. In the first two courses students learned the basics of Geographic Information Systems (GIS), remote sensing techniques, archaeological survey skills, ground-truthing, fieldwork, approaches to mitigation, threat identification skills, measurement techniques, presentation skills, site stabilization strategies, and collaboration with various stakeholders in the process. These elements of the ASP were taught with classroom, computer lab, and field components. As the Iraqi Institute further develops its ASP syllabus we look forward to working with colleagues from the SAA.

R. Roney (Colinas Cultural Resource Consulting)  
[47] Settlement Structure in Central and Southern Chihuahua  
The absence of a sizable, distinctive Precolonial society in central or southern Chihuahua has long been recognized. Based on several field seasons of reconnaissance, systematic survey and limited excavations, it is evident that the area was populated by generally dispersed groups of people, with instances of aggregation being limited in frequency and scale. Assemblages from sites throughout many parts of the region indicate prevalent localized resource selection. On tentative evidence, there are several highly localized ceramic traditions, though all are dominated by the use of plainware and less than ten percent decorated pottery. Even the largest known sites are lacking evidence for large populations.

Within central and southern Chihuahua along the foothills and in the Sierra Madre Occidental, rainfed farming is viable. With a major constraint on available farming locations eased, variable or low agricultural productivity prevailed, along with the use of many wild food resources while settlements were dominated by dispersed rancheras.

Harding, Gregg (Florida Public Archaeology Network) and Jess Hendrix (Florida Public Archaeology Network)  
[228] Heritage Education within High School: A Public Archaeology Case Study of the Scott Site  
In the fall of 2012 the Florida Public Archaeology Network (FPAN) Northwest Region continued a long-term public archaeology program in partnership with students from Milton High School’s Anthropology/Archaeology class. Once a week students meet with graduate students from the University of West Florida at the Scott Site, an early to mid-19th century brick-making operation located in northwest Florida. At the Scott Site, high school students participate in hands-on archaeological methods and act as contributors to on-going anthropological research. Through field surveys and excavations, the use of remote sensing technologies, and the practice of site interpretation, students from Milton High School have been able to grasp an early understanding of site stewardship and the importance in preserving their local history. This paper highlights the successes and challenges of creating and maintaining a hands-on public archaeology program within a high school setting.

Hardy, Meredith (National Park Service)  
[96] New Directions in Archaeological and Cultural Heritage Education  
The Public Education Committee serves as a nexus for heritage education and communication between federal, state, and local agencies, academia, and the private sector. With the explosion of the internet and online information in the 1990s and beyond, the public has become savvy when searching for basic or introductory information about archaeological and cultural heritage, but in many cases this information comes across as passive, trite, and dated. How do you reach an audience that is accustomed to instant access to information in a format that catches their attention and drives home a message? This paper presents some of the ways the National Park Service, through the national Heritage Initiatives, educates and engages the public with the places that comprise our shared and diverse cultural and historical heritage, and the value of their protection and preservation.

Hardy, Thomas (University of Pennsylvania)  
[231] Wari Colonialism in Middle Horizon Peru: Preliminary Results from the Site of Minaspata, Lucre, Cuzco  
The Wari state (AD 600-1000) expanded from its heartland in the central Andes throughout various parts of highland and coastal Peru, installing invasive colonies, reorganizing settlement patterns in some areas, and disseminating a distinctive material culture over wide swaths of the Andes. Recent research has pointed out that Wari colonization is much more intensive in some areas than others, and that evidence of more complex interactions can be seen in many regions. Some scholars have begun to recognize the importance of shifting our attention to local contexts and settlements where the colonial encounter took place, linking this shift to broader theoretical approaches focusing on local agency and cultural hybridity. Toward this end, research was conducted at the site of Minaspata, a 35-ha, multi-component site located in the Cuzco Valley near the Wari site of Pikillacta, with the goal of investigating the social and cultural transformations which occurred as a result of Wari colonial practices. Minaspata was a local site occupied continually from the Early Horizon (B.C. 800 – AD 1) to the Late Horizon (AD 1476-1531). Preliminary results from the 2013 field season at Minaspata are presented here.
Hare, Timothy (IRAPP, Morehead State University), Marilyn Masson (SUNY, University at Albany) and Bradley Russell (College of St. Rose)

[337] The Mayapan LiDAR Mapping Project
A 2013 survey of a 40 square kilometer area surrounding Mayapan, Yucatan, Mexico used high resolution LiDAR data to map prehispanic architecture and related natural features. Most of the area is covered by low canopy dense forest vegetation over karstic hilly terrain that impedes full coverage archaeological survey. We used LiDAR at forty laser points per square meter to generate a bare earth digital elevation model (DEM). Results were evaluated with comparisons to previously mapped areas and with traditional archaeological survey methods for 38 settlement clusters outside of the city wall. Ground checking employed full coverage survey of selected 500 m grid squares, as well as documentation of the chronology and detail of new public and domestic settlement features and cenotes. Results identify the full extent of continued, contemporary Postclassic settlement (A.D. 1150-1450) outside of the city wall to at least 500 meters the east, north, and west. New data also reveal an extensive modified landscape of terraformed residential altillos, rejolladas, and dense settlement dating from Preclassic through Classic periods. The LiDAR data also allow for the identification of rooms, benches, and stone property walls and lanes within the city.

Hargrave, Michael (ERDC CERL), R. Berle Clay (Southern Illinois University-Carbondale), Rinita Dalan (Minnesota State University Moorhead) and Diana Greenlee (Poverty Point State Historic Site)

[263] Posts at Poverty Point: A View from Haag’s Rise
The discovery of numerous post circles in magnetic surveys at Poverty Point has led us to take a closer look at the possible significance of the site’s other, seemingly unpatterned (non-circle) posts, particularly those located at “Haag’s Rise”. That landform is located where the central aisle enters the plaza, opposite Mound A. Haag’s excavations in the 1970s encountered 47 massive postholes that did not form recognizable patterns and contained few artifacts or soil stains. The density of features in his two excavation units, if extrapolated, suggests that several thousand massive postholes could be present at and near the rise. That projection is not supported by the modest number of magnetic anomalies consistent with non-circle posts, but Haag’s excavation results may have helped us identify a bias in the survey. The posts at Haag’s Rise may be significant in several ways. If numerous, they would represent a substantial expenditure of energy and perhaps an ongoing requirement for organized communal labor. Posts could have provided a versatile, visually compelling means of marking astronomical or other alignments as well as important locations within the site. Post circles and non-circle posts may well represent an important, previously underappreciated component of the Poverty Point landscape.

Hargrave, Eve, Julie Bukowski (Illinois State Archaeological Survey/Prairie Resea) and Lenna Nash (Illinois State Archaeological Survey/Prairie Research)

[272] Death and Sacrifice in the American Bottom
Single burials and isolated human elements have been discovered in association with large post pits at several late prehistoric sites in the American Bottom region of Illinois, including the East Saint Louis Mound Center. The location, burial positioning, and sex of these individuals, and isolated elements suggest intentional deposition of human remains. Feature profiles illustrate that these burial events were associated with the removal and refilling of large marker posts. The use of posts to mark sacred space, and the association of ritual offerings and human sacrifice with sacred space, have been identified on a larger scale within Mound 72 at the American Bottom Mississippian mound center of Cahokia. These offertory burial events and evidence for human sacrifice are all associated with the early Mississippian Lohmann and Stirling phases (A.D. 1050-1200). This paper focuses on the unique relationship that exists between human sacrifice and the delineation of sacred space during a period of significant ideological and political change.

Harke, Ryan

[96] Towards a Public Environmental Archaeology: History, Survey and Suggestion
The Florida Public Archaeology Network (FPAN) is a state-wide archaeology organization established by the Florida Department of State, with goals to conduct outreach and education, assist local governments, and support the Division of Historical Resources. FPAN is a 9-year experiment in the programming of full-time public archaeologists, and thus, the accomplishments that such an organization could achieve. As a result of this multi-year experience, we suggest that long-term, effective public archaeology is more easily
achieved under models that employ full-time staff. Although the numerous workshops, trainings, and partnerships are immensely successful in supporting outreach goals, surveys of research in ecological archaeology and the success of environmental education reveal the untapped potential for collaboration between environmental science programmers and public archaeologists. This interdisciplinary effort is imperative to highlight the historical impacts of humans on the natural environment and how archaeology is useful in addressing modern environmental problems.

Harkness, Rebecca (Arizona State University)
[43] Track and Shield: Exploring the Connection between Racetracks and Shield Petroglyphs on Perry Mesa

The late prehistoric (A.D. 1280-1425) occupation on Perry Mesa in central Arizona is uniquely characterized by an abundance of formal racetracks. Will Russell has argued that the racetracks hint at an overarching social network and were used as ritual venues. Rock art is also common on Perry Mesa, and diverse motifs have been systematically recorded over the past decade. A particular motif, the shield petroglyph, is the focus of this study. As part of the 2013 Legacies on the Landscape field season I undertook two spatial analyses of seventeen of these petroglyphs distributed among seven sites on Perry Mesa and Black Mesa in the Agua Fria National Monument. The purpose of this study is to determine whether a spatial correlation exists between shield-like petroglyphs and ritual racetrack sites which could indicate a ritual connection. Such a correlation exists among the pueblos of the Northern Rio Grande area, which is a possible destination for Perry Mesa migrants when they left central Arizona in the early-mid 1400s.

Harlan, Mark (Dos Locos Consultores, LLC)
[179] A Semiotic Approach to Variability in Formative Period Mesoamerican Anthropomorphic Figurines

Anthropomorphic figurines are commonly encountered in substantial numbers on Mesoamerican sites occupied throughout the Formative Period, a feature these sites have in common with pre-state villages around the world. Most past studies have either used traditional typological approaches to use the figurines for chronological control or perused the collections for interesting clues to the appearance or concerns of the prehistoric peoples who created them. Systematic typological analysis cross-cuts much of the variability while most studies searching for connections to past communities rely on impressionistic observations that focus attention on unusual aspects of figurine variability rather than regularities. This paper discusses an approach to figurine variability that relies on semiotics in an attempt to combine systematics with attention those aspects of variability most likely to illuminate past lives.

Harlow, Jeanette (California State University, Long Beach), Elizabeth Niespolo (California State University, Long Beach), Sachiko Sakai (California State University, Long Beach) and Carl Lipo (California State University, Long Beach)

Moapa Gray Ware, a unique olivine-tempered pottery type seen widely in the Anasazi region, derives from Mt. Trumbull on the Uinkaret Plateau and is frequently found in surrounding areas. This project explores why Moapa Ware could be considered functionally advantageous over other cookware types that would have been more easily obtained by people not directly local to Mt. Trumbull. Thermal gravimetric analysis (TGA) and differential scanning calorimetry (DSC) compares thermal characteristics between the olivine-tempered Moapa Ware, Moapa Ware grog-tempered Shivwits Ware, and a generic sand-tempered ware. All were analyzed using X-Ray Diffraction, confirming temper mineralogy and eliminating the possible ceramic clay sourcing as a distinguishing manufacturing characteristic. Samples tested with TGA from each ware type show minimum firing temperatures of above 950°C, indicating no pyrotechnical distinguishability of Moapa Ware from other ware types. Preliminary DSC results demonstrate potential functional differences between ware types based on their respective heat capacities. All ware types demonstrate peak exothermic reactions at approximately 500°C. Sand-tempered samples and Shivwits Ware samples do not sustain exothermic reactions beyond 590°C, indicating inefficient high-temperature heating. Moapa Ware samples show the highest exothermic reaction range of up to 648°C, indicating a possible high-heating functional capability of this ware type.

[124] Place, Politics, and Local Knowledge: Methodological Lessons from Yalburt Landscape Survey
Yalburt Yaylasi Archaeological Landscape Research Project is a diachronic regional survey, investigating a small but coherent region in central western Turkey. Since its first season in 2010, yearly field operations have combined archaeological survey, geomorphological research, and informal ethnographic interviews to understand the long term history of settlement in this little explored karstic landscape of highland pastures, river valleys, and lowland plains around the modern town Ilgın, west of Konya province. The core research objective of the project is to understand the tense interaction between local cultures and imperial powers at the time of the Hittite Empire (Late Bronze Age, 15-12th c. B.C.E.) through the evidence of state interventions into the region, evidenced through programs of new settlement, agricultural rehabilitation, and irrigation. Methodologically, the project advocates an archaeology of place that does not isolate ancient (so-called authentic) landscapes from contemporary (supposedly degenerate) ones but emphasizes the connections, ruptures, and continuities between the ancient and modern landscapes. Using the results of the last four seasons of fieldwork, this paper will argue that place-based approaches in survey archaeology supported by geomorphological and ethnographic work are fundamental to understand long term practices of land use and the production of indigenous knowledge about landscapes.

Harmon, Brian

[344] Don't Be Deceived by Small Pueblo Room Blocks
Although small Coalition Period (A.D. 1200-1325) pueblo room blocks on New Mexico’s Pajarito Plateau appear to be relatively uniform when discovered on survey, excavations conducted during Los Alamos National Laboratory’s (LANL) Land Conveyance and Transfer (C&T) Project suggest that surface appearances mask architectural variability representing different ceremonial and economic emphases. In this paper I explore evidence indicating that greater stress was placed on agricultural activities at sites without formal ceremonial structures than at sites with formal ceremonial structures. Analysis of four excavated C&T pueblos demonstrates that larger habitation and storage rooms coupled with a greater ubiquity of maize kernels characterize non-kiva sites whereas sites with kivas contain smaller rooms and less maize. To discover if there is additional evidence of this architectural-agricultural correlation I compare the groundstone assemblage size, groundstone assemblage content, and maize pollen ubiquity of these four sites. Finally, I examine room size, kiva presence, maize ubiquity, and groundstone assemblage data from other small, excavated Coalition Period Plateau room blocks to determine if the identified pattern is observed in a larger sample.

[300] Working for the Man: Constructing the Cyclopean Tomb and the Treasury of Atreus at Mycenae, Greece
The evolution of state power at Mycenae, Greece, in the Late Bronze Age has often been discussed through the lens of monumental architecture. Particularly, the development of the distinctive stone “beehive” tombs or tholoi from the Late Helladic II (LHII) to Late Helladic III (LHIII) is viewed as mirroring the growth of the state over that period. Recently, an architectural energetics approach has been used to bolster this idea by illustrating the increasing labor-cost of tholos construction over time. This study approaches the problem of tholos construction in more detail by specifically comparing one of the latest tholoi, the Treasury of Atreus, to one of the earliest, the Cyclopean Tomb. Using three-dimensional CAD models, I highlight the disparate building techniques used in these tholos tombs. I present detailed breakdowns of labor-costs, and I simulate how the construction of each tholos would have been organized in time and space. The results of this analysis suggest that the transformation in tholoi at Mycenae between LHII and LHIII was not simply the result of increasing labor investment, but that it also represents a deep-seated change in labor recruitment strategies, managerial abilities, and technical knowledge.

Privacy, Performance, and Production: Sensory Aspects of Domestic Production and Household Industry in Classical and Hellenistic Greece

Evidence from ancient house plans and contemporary literature suggests that household privacy was a high priority in many ancient Greek cities. The apparent ideal of perfect household privacy was not attainable in practice, however, and various household activities were sure to draw the attention of the neighbors. Excavations of Greek houses indicate that many households were producing craft objects or processing agricultural surplus at a scale beyond that required for their own needs. Some craft people even engaged in pyrotechnologies at home within the city, including firing ceramics or smithing metals. This paper explores the tension between the desire for household privacy and the inevitable notice drawn by the sights, sounds, and odors of production in an urban environment in the cities of Athens, Olynthus, and Eleutherna. I argue that rather than being part of a "hidden" economy, Greek domestic production and household industry were more strongly integrated into the formal economy and the sensory aspects of such production were part of the experience of everyday life in the city. Household industry was still performative, even when conducted within the “privacy” of the home.

Assessing the Trapezoidal Array for Archaeological Earth Resistance Investigations

Earth resistance is a well-established technique for archaeological prospection. Even though it has proven effective, earth-resistance surveys have a reputation for being slow and time consuming. Since rapid data collection is often an important factor for survey work, especially over large areas, earth resistance is reserved for targeted areas. Traditional electrode configurations, such as the twin-probe array, do have a slower rate of data collection compared to other prospection techniques. However, the adoption of non-linear electrode configurations, such as the square array, to mobile platforms has increased earth resistance’s efficiency for large-scale survey work. Mobile platforms increase the rate of data collection and facilitate more flexible survey strategies. Still, the square array possesses certain properties, such as a limited depth of investigation and orientation dependences, which lessen its effectiveness for archaeological investigations. These drawbacks warrant further research into a more effective array. This paper explores the trapezoidal array. The results from a series of experiments assessing trapezoidal array properties, such as depth of investigation, apparent anisotropy, and resolution, show the trapezoidal array is an effective configuration for archaeological prospection, demonstrating its potential for further development and applications.

Harris, Khadene (Northwestern University) and Mark Hauser (Northwestern University)

Post Emancipation Shifts: Land, Labor, and Freedom on the Bois Cotlette Estate, Dominica after 1838

This presentation focuses on the actions of the newly freed population on the Bois Cotelette Estate in Dominica in the aftermath of full legal emancipation in 1838. I explore the ways the actions of the formerly enslaved reflected specific ideas of freedom and the implications for the ways in which power was (re) defined in societies that no longer employed slave labor. In the years after slavery, land and the economic opportunities connected with landownership were important in individuals’ decisions about where to go and what to do. Thus, the postemancipation period—like its antecedent—is extraordinarily significant in terms of understanding how various territories in the Caribbean were reconstituted in particular ways. In many ways the historiography of post emancipation societies has been uncritical of the concept of freedom in the post emancipation era. I attempt to show this by mapping house areas that were constructed on the Bois Cotlette Estate for the laboring class after slavery ended. I further highlight changes in the layout of these house areas as compared to the pre-emancipation period to show how the newly freed perceived and acted upon legal emancipation.

The Multifunctional Lives of Points and Flakes: An Experimental Study

The terms “projectile points” and “flakes” imply that these tools have only one function. On the contrary,
we argue that these are multipurpose tools. Specifically, we explore their efficiency as sawing implements. While we initially hypothesized that flakes would be less efficient than hafted bifaces, the results of this study show that retouched flakes are infinitely more efficient at sawing than hafted bifaces. Due to the efficiency of retouched flakes, and the fact that there is minimal investment to create them, retouched flake tools should always be preferred over hafted bifaces for the task of sawing. There is little likelihood that a prehistoric hunter-gatherer would choose to use a hafted biface as a saw when flakes are available. This study serves as a useful springboard for a better understanding of tool function, and more importantly, it demonstrates the significance of cognitive human design of lithic tools.

[234] Digging up the Junk in Grandpa’s Basement: An Analysis of the Lithic Artifacts from the Lane Family Collection
This poster presents an analysis of the Lane family collection donated to the Laboratory of Archaeology at the University of British Columbia in 2009. The Lane family collection has a diverse curated assemblage of lithic, bone, and other materials collected from a variety of locations but with its own system of organization and cataloging. The inherent system of organization and cataloging implies appreciation for provenience and respect for the artifacts themselves. I discuss the distribution of lithic typologies and raw materials among the Lane family collection, and postulate techniques in identifying a general provenience for lithic materials. The identification of a general provenience allows the use of these specific artifacts from the Lane family collection, and potentially other artifacts from other donated collections, in either a teaching or research setting.

[246] The Southwest German Regional Archaeological Survey Project: Twenty Years of Research on the Federssee Lake
The Southwest German Regional Archaeological Survey Project was initiated by Mike Jochim in 1992. It has focused on the archaeologically rich area surrounding the Federssee Bog and Lake as well as two smaller bogs to the south. The study area includes a transect centered on the Federssee Lake extending from the Danube River in the North to Lake Constance in the South. The project was designed to explore the landscape through first mapping the distribution of all previously known sites in the region, and then adding an extensive regional survey of plowed fields to record locations both with and without archaeological finds to create a broader and less biased database of site locations for the study area. The goals of this project were to explore regional landuse, test assumptions about the level to which Stone Age groups focused their activities on the Federssee and other bogs, and then look for changes in the landuse patterns during the course of the Stone Age. The data collected during the over 20 years since the project began provide the basis for some observations about the initial research questions as well as new questions about regional survey data and methods.

Harris, Lucille (Applied Archaeological Research, Inc.)
[290] An Entanglement of Boxes: Navigating the Web of Theory and Ethnography in Plateau Archaeology and Charting One Possible Course Out of the Interpretive “Box”
This paper is premised on the belief that archaeological interpretation of Late Prehistoric Northern Plateau archaeology, particularly that of the Mid-Fraser region, has been constrained by both theoretical and ethnographic considerations. Importantly, however, I argue that theoretical perspectives that forefront nonegalitarian social and political organization have exerted an unprecedented influence on our uses of the ethnographies. Thus, while we need to escape the ethnographic box that we have constructed, we also need to step outside of the theoretical box that we used to build it. In this paper I will examine the relationship between archaeological theory and applications of ethnographic analogy that are at the base of archaeological interpretation of Mid-Fraser archaeology. Having deconstructed this relationship, I will provide an alternative theoretical perspective that focuses on the social construction of leadership and networks of social relationships in Plateau society that draws heavily, but less selectively, from a historically situated understanding of the regional ethnographies. In so doing, this paper will demonstrate one possible course out of “The Box”.

[29] Scales of Resilience and Exchange in Medieval Iceland: Sustainable Transition from Small Scale Subsistence Economy to Proto-World System Participation
This paper presents a set of scenarios on long term human-ecodynamics from four different economically organized components of the Eyjafjörður region’s cultural and environmental landscapes, all resulting
from transdisciplinary research efforts. The harbor and trade site complex at Gásir with its large medieval Merchant’s Church and the monastic estate at Möðruvellir were part of the central areas. Möðruvellir, a large-scale landowner, under the Northern Bishopric at Hólar, undoubtedly influenced the movement of goods across the region, the exchange at Gásir, and the economic strategies of a large proportion of cottages and smaller scale farming operations in the Möðruvellir and Gásir Hinterlands. These hinterlands, and especially steep-sloped and narrow-spaced Hörgá Valley as closest supplier of animal products, provide archaeological and environmental data informative about this medieval economic system’s transformation from local and regional to internationally oriented exchange. Siglunes, a fishery site in Siglufjörður, provides insight into early Icelandic fishing exchange. Siglunes very likely supplied the dried cod fish filets that were part of the bulk goods moved abroad via Gásir’s harbor. The interplay of all these various components is used to demonstrate sustainable farming and fishing practices in this region from the time of Settlement to the High Middle Ages.

Harrison, Rebecca (The University of Sheffield)
[209] When and Why Did Handedness Evolve?
It might be supposed that having two equally skilful hands would ensure maximum manipulative ability, however in humans complex manual tasks are performed more effectively when one hand is dominant. It is widely stated that 90% of all modern humans are right handed and that this correlates with asymmetries in the brain’s language areas. There is evidence for right handedness throughout human evolution: in stone tool manufacture (1.4 to 1.9 million years ago); tool use (130 000 years ago); and Upper Paleolithic cave art (approximately 27 000 years ago). In contrast, evidence for handedness in nonhuman primates is ambiguous, and research carried out by the current author has not found convincing evidence that handedness exists, other than sporadically, in nonhuman apes. However there is evidence in nonhuman apes for asymmetries in the brain in areas which are homologues of the language areas in humans. A possible explanation for this which will be investigated here, is that this asymmetrical neural pattern performs functions relating to gestural communication in nonhuman apes, and that handedness evolved as spoken language gradually replaced gestural language. This would have both facilitated the transfer of information, and simultaneously left the hands free to perform manipulative duties.

[330] Colonial Period Cultivation and Commodification of Cacao in the Maya Lowlands
Currently, we know more about cacao consumption in Mesoamerica than its production. In colonial contexts, our understanding of Maya cacao cultivation, its "value," and commodification during the sixteenth and seventeenth centuries comes primarily from the Spanish ethnohistoric accounts. According to these accounts, Belize was one of several important cacao-producing areas at the time of contact. However, scholars have been largely unsuccessful in identifying the locations of cacao production in the archaeological record. Here we discuss our investigations in the middle Belize Valley where the Spanish recorded a series of contact period Maya settlements with sizeable cacao orchards that came under the control of the Spanish encomienda system during the colonial period. We present preliminary results of soil testing in Belize where we have been able to detect a cacao biomarker. We discuss this new technique, which may offer the first viable method for identifying historic (and possibly prehistoric) cacao orchards in the archaeological record. As a "frontier" zone, the middle Belize Valley engaged in both the European and Maya ("Black Market") economies and offers a unique context in which to review how these competing economies impacted the production and "value" of cacao during this transitional time in Maya history.

[126] Embodiments of Conflict and Cooperation: A Biocultural Analysis of Violence and Social Inequality in the Ancient U.S. Southwest
Archaeological reconstructions focused on the people living in the Southwest portion of the United States around the Chaco Canyon cultural area (A.D. 850-1250) reveal a complex and sophisticated world centered around practice and performance. The Ancestral Pueblo populations living in this region offer a unique case study for exploring the ways in which people interact with and are impacted by their landscape, architecture, and material culture. The primary goal of this presentation is to identify patterns
of nutrition, activity, health, and trauma found on the human skeletal remains in order to provide insight into the embodiment of sociopolitical and ideological structures that reinforced and promoted violence and social inequality. The project involves the analysis of over 200 complete and incomplete burials recovered from seven sites in and around Chaco Canyon using a biocultural approach that evaluates markers left on the bones within the environmental, cultural, and sociopolitical context. Findings suggest that there were institutions in place in the U.S. Southwest during this period that resulted in differential patterns of trauma, health, and labor.

Changing Subsistence and Interaction Patterns in the Mt. Dellenbaugh Region of the Shivwits Plateau, Northern Arizona

The Mt. Dellenbaugh region of northern Arizona was first settled by Virgin Branch Puebloan farmers during the middle Pueblo II period (about A.D. 1050). Ceramic evidence suggests that these settlers came from diverse backgrounds and maintained ties with people in different regions. Settlement expanded during the next century before the area was abruptly abandoned during the early Pueblo III period. This paper traces the changes in subsistence and interaction patterns that occurred in the region during the century or more of occupation, and considers the implications of these findings for understanding the final abandonment.

Hart, Thomas (University of Connecticut)

Preliminary Analysis of Phytolith Production Patterns in Select Non-Grass Southwest Asian Plant Taxa

Phytoliths are becoming an increasingly important tool in archaeological, forensic, paleontological, and nanotechnological research. Deborah Pearsall has been a pioneer in emphasizing the importance of understanding phytolith production patterns and in discovering phytolith types that can be used to reconstruct various aspects of human/plant interactions. In this project, I analyzed 354 samples from 181 select non-grass species commonly encountered in Southwest Asian archaeological soils. Southwest Asia has played a pivotal role throughout history and prehistory due in large part to its geographic location at the intersection of Asia, Africa, and Europe. To date, the majority of phytolith research in this region has focused on understanding production patterns in plants commonly consumed by humans. This project was focused on understanding phytolith production patterns in non-grass, predominately weedy taxa. The results of this study have added to the growing body of knowledge surrounding phytolith production in general and helped to clarify what species do and do not produce phytoliths in Southwest Asia.

Setting the Record Straight: Ethnography of Montezuma Castle and Tuzigoot National Monuments

The Spanish explorer Espejo’s 1583 trip through the Verde Valley of central Arizona may constitute the first written accounts regarding Native American use of resources at what is today Montezuma Well, a unit of Montezuma Castle National Monument in Yavapai County. Despite these and subsequent accounts, many cultural connections to archaeological sites throughout the valley have been ignored and forgotten by some. Indeed, the National Park Service (NPS) itself reported to Congress in 1915 that the local Yavapai people did not have any connections to the former inhabitants of the valley. Today’s Montezuma Castle and Tuzigoot National Monuments are jointly managed, including the Montezuma Well Unit. Together they represent three points within the larger archaeological landscape with ties to many extant peoples. This research records, synthesizes, and promotes cultural resources and the connections which tribes still have with these NPS sites. Hopi, Yavapai, Apache, Zuni, and Southern Arizona tribes are represented. The data presented supports the NPS through historic preservation, interpretation, and management decisions involving these archaeological sites. Those decisions, when better informed by tribal input and increased awareness of ethnographic resources, in turn benefit culturally associated tribes.

Comparing Paleoecological Proxy Data to the Archaeological Record in Rance Creek Canyon, Utah

We are comparing climate and vegetation proxy data to archaeological data in Range Creek Canyon,
Utah. Data for pollen abundances, local fire histories, and sediment composition including stable isotope chemistry, were derived from several sediment cores and tree-ring samples within the canyon. These data provide a detailed prehistory of ecological conditions in the canyon before, during and after the expansion of Fremont-era archaeological sites here between roughly 800-1100 A.D. Using models from Behavioral Ecology and experimental data regarding energetic return rates for various taxa, we estimate the availability and productivity of key food resources and predict their inclusion or exclusion from the forager diet in the canyon, including the adoption or abandonment of maize agriculture.

[206] Environmental Causes of the Extinction of the Pleistocene Megafauna in the Desert Southwest
The extinction of Pleistocene megafauna in North America is a source of heated debate. There are many theories to explain this event. The most widely accepted theories are overkill and climate change. Mammoths and other proboscideans are the most common megafauna at Pleistocene-aged North American sites and are thus most widely studied. This research covers environmental factors of the extinction. Climate change had the greater contribution, with overkill finishing the remaining populations. This poster discusses several megafauna sites and Clovis kill sites in the Desert Southwest (i.e., Sonoran and Chihuahuan Deserts), a region with abundant sites and megafauna diversity. Clovis-age sites include Murray Springs, Lehner, Naco, and M and M (all in Arizona) and El Fin del Mundo (Sonora). Older Megafauna sites include Isleta Cave, Lake Otero, and Lake San Agustín (all in New Mexico), the Borrego Badlands (California), Prescott Valley and the 111 Ranch Beds (both in Arizona), and the Upper San Pedro Valley and Térapa (both in Sonora). This study compares different taxa and their relative abundance at pre-Clovis-age and Clovis-age sites to show which taxa survived to the terminal Pleistocene. It is expected that megafauna were already declining before Clovis people arrived.

Harvey, Allison (White Sands National Monument)
[87] Experimental Hearth Reconstruction at White Sands National Monument
Cultural sites known as “hearth mounds,” scattered throughout the gypsum dune field of White Sands National Monument in south-central New Mexico, have the potential to provide additional insight into human habitation and subsistence strategies within the Tularosa Basin. These sites contain the remains of prehistoric thermal features which transformed the surrounding gypsum sediments into a hardened material similar to plaster of Paris. This paper explores the formation processes that influence the spatial and temporal relationships between Middle Archaic through Pueblo period (4300 B.C. – AD 1450) hearth mound sites and presents the results from an experiment designed to replicate simple cooking facilities described ethnographically for Mescalero Apache and other Southwestern pueblos. The data collected during and following the experimental hearth reconstruction provide a more robust understanding of site function, resource availability, recycling strategies, and the potential number of firing episodes, as well as a site’s preservation potential.

Hasaki, Eleni (University of Arizona)
[332] Potters’ Skills and Secrets: The Potter’s Wheel in Ancient Greece
Greek vessels are predominantly formed on the wheel by experienced potters. Limited evidence on potters’ wheels includes philosophical references, pictorial representations, and several prehistoric clay discs interpreted as rotating mats or wheel-heads. The entire apparatus of a potter’s wheel has not yet been excavated, either in prehistoric or historical contexts. Athenian and Corinthian depictions show potters, mainly in a seated position, using a low, hand-turned wheel, often assisted by younger workmen. Experimental data from constructing and operating a modern replica of an ancient potter’s hand-operated wheel highlights the challenges of its form. It also examines the relationships between speed and weight of clay as well as weight of wheelhead. This paper will incorporate archaeological, iconographical, experimental, and ethnoarchaeological data to evaluate optimal construction materials and design of
ancient Greek wheels and to elucidate issues of wheel operation and size-related specialization in wheel-throwing.

Hassler, Gabriel  
[231]  Archaeobotany of the Reducción Movement in Peru  
During the reducción movement in Peru, as many as 1,500,000 people were forcibly resettled by the Spanish colonial government into planned towns called reducciones. While this process was ostensibly designed to evangelize and "civilize" local populations, it also facilitated the Spanish consolidation of political authority. While the movement was enormous in scope, few primary historical sources provide any information as to how it was practically implemented. As part of the Proyecto Arqueológico Zaña Colonial, the research presented here attempts to discover how the reducción movement was implemented on the north coast or Peru and the effect it had on the local population. Macrobotanical remains from reducciones and late prehispanic sites in the Zaña valley will be compared to see what effect the reducción movement had on diet and subsistence.

Hastorf, Christine (University of California-Berkeley)  
[27]  The Actions and Meanings of Open and Hidden Performances at Formative Chiripa  
From recent excavations the Taraco Archaeological Project has completed, in addition to the previous work by Bennett, Kidder, Portugal, and Browman at the Middle Formative settlement and ceremonial site of Chiripa in the shores of lake Titicaca in highland Bolivia, we have discovered a stepped, nested set of civic ceremonial spaces, linking the lake-shore to the highest interior sunken enclosure. The ceremonial tradition in this region seems to be made up of multiple locations at one site, where different activities occurred. At times the more open spaces were used for daily tasks, but the closed spaces were more restrictively used. These spaces and their sensory impact will be discussed as they reflect the scale of ceremony, with suggestions for shifting experiences with the heavens, the lake as well as inter-personally.

A Winnemucca (dry) Lake, Nevada, petroglyph panel at site 26Wa3329 was coated by a calcium carbonate layer deposited during a high lake stand about 10,000 calibrated RCYBP. Additional radiocarbon dating, geochemical analyses, paleo-lacustrine studies and regional archaeology support a likely interval for creation of the underlying petroglyphs between about 10,500 and 11,300 calibrated RCYBP, although they could be as old as 14,800 calibrated RCYBP. This petroglyph site is very distinctive and the associated petroglyphs are comprised of large, deeply incised geometric elements. Sites sharing design or technological attributes are known from elsewhere in the western Great Basin.

[283]  Helping with the Previously-Deceased: Legal and Logistical Problems Encountered in Responding to Cemetery Damage in Louisiana from Hurricane Isaac
In the wake of natural disasters, local and national officials often seek the expertise of forensic archaeologists and anthropologists in the recovery of disinterred human remains. In South Louisiana, where bodies are usually entombed in above-ground vaults, the use of recovery archaeology can be vital in preserving cemeteries and memorial grounds. We discuss our experiences as first responders in the early phases of the recovery of human remains in Louisiana after Hurricane Isaac, focusing on the legal and logistical problems encountered. We propose a set of uniform response guidelines that might prove useful to local officials concerning such recoveries.

[305] The Soil Resources of Uci and Ucanha, Yucatan, Mexico
This paper examines the agricultural potential of soil resources around the sites of Ucí and Ucanha, located on the coastal plain Yucatan. Shallow soils in the karst landscape produce low maize yields. The ancient Maya of Ucí were connected to both secondary centers as well as villages by a stone causeway. A survey of the soil resources of the archaeological site and its hinterland to the east has revealed an extremely difficult setting in which to grow crops and thrive. The inhabitants of Ucí and Ucanha chose to cluster around natural depressions called rejolladas that contain deep soils with the highest agricultural potential. The small area of the rejolladas limited crop production, however. Soils of the rejolladas exhibited weak carbon isotope evidence of both contemporary and ancient C4 maize agriculture. The shallow soil resources of Ucí outside the rejolladas are not conducive to the production of high yield maize crops.

[278] Lapa do Picareiro: A 50,000-Year Record of Human Occupation and Environmental Change in Central Portugal
Lapa do Picareiro has yielded a continuous, stratified sedimentary sequence that provides a diachronic record for MIS 3 and MIS 2 human occupation and environmental reconstructions. We present data from the 2005-2013 excavation including results of faunal, artifactual and sedimentary analyses. The spatial distribution of lithic and bone artifacts suggest sporadic, short term visits to the cave prior during most of the Early Magdalenian, Solutrean, Gravettian and Middle Paleolithic. The ungulate, rabbit, micromammal, bird and amphibian remains are used here to understand the taphonomic formation of the assemblages from Picareiro. Results suggest inputs by Neanderthals and anatomically modern humans, the Iberian lynx and raptorial and scavenging birds. Humans and lynx were likely responsible for most of the large mammal and rabbit as well as some birds. Raptorial birds likely preyed on the rodents, especially voles, amphibians and small birds. Vultures and carrion crows are present and also likely contributed many mammal remains. The fauna therefore derive from multiple sources and provide a balanced paleoenvironmental record to understand human responses to long-term environmental change in central Portugal.

[25] Prepared to Be Remembered: Trophy Head Production and Meaning among the Prehispanic Ramadas of Southern Peru
Although trophy heads in the Andes have been explored from multiple vantage points, few studies have focused on the technical aspects of creating trophy heads, nor the degree of specialization associated with this practice. Recent excavations in the Vitor Valley of southern Peru have uncovered several trophy heads in a single prehispanic cemetery. Both fully fleshed heads and skulls from male individuals were recovered and were processed in a way that appears to intentionally maintain the face, and thus the identity of the victims. Furthermore, the locations of the perforation in the frontal bone and the partial
removal of the occipital appear to be similar, suggesting some uniformity of practice. Still, a detailed osteological study of these human remains reveals enough variations in technique that we question whether there was any enforced standardization in trophy head production that would indicate that this was part of a highly specialized activity. We, therefore, propose that these recognizable heads may have been produced, curated, displayed, and used predominantly at the household level. We discuss what this distinct practice says about body concepts within the socio-political milieu of the Ramadas tradition in southern Peru.

Hays-Gilpin, Kelley (Northern Arizona University), George Gumerman (Santa Fe Institute), Dennis Gilpin (PaleoWest Archaeology) and Lisa Young (University of Michigan) [202] Picturing Early Pueblo Communities

One of Linda Cordell’s ongoing “for fun” research interests was a set of Pueblo I painted pottery bowls that depict human figures holding hands in an apparent group dance. These figures often have butterfly hair whorls, today associated with Pueblo women’s puberty initiations. Similar groups also appear in rock art. The images have a very broad distribution from southwest Colorado to Houck, Arizona, where George Gumerman excavated such a bowl in 1966 during Interstate-40 salvage. In this paper, we explore what these depictions tell us about community dynamics at this critical time in the development of early Pueblo communities.

Hayward, Michele (Panamerican Consultants), Frank Cahieppati (Panamerican Consultants) and Michael Cinquino (Panamerican Consultants) [248] Rock Art and Location on Puerto Rico

Rock art is found at three principal locations throughout the Caribbean-ball court, cave and open air (river boulders; other location rock formations). These proportions vary by island with Puerto Rico possessing a substantial number of all three. Previous studies have identified similarities and differences among general rock art categories, such as between petroglyphs and pictographs. In this paper we explore via statistical measures possible locational assemblage signatures that might be expected to vary along a continuum from the large-scale open public ball court contexts, to smaller-scale, but still accessible and public waterway and inland rock formations, to more circumscribed and private caves.

Hayward, Douglas [288] see Chacon, Richard

Hayward, Anne (Pennsylvania State University) [336] The Textiles of El Gigante, Honduras

The El Gigante site was located in a shallow rock shelter in southwest Honduras. Eastern exposure and sandy floor insured excellent preservation of human, faunal, and botanical remains. Evidence of looting pits precipitated its excavation by the Instituto Hondureño de Antropología e Historia (IHAAH) in 1993 and 1994. In 1998, members of the Pennsylvania State University Anthropology Department joined IHAAH and excavated living areas and burials. Radiocarbon dating put human occupation from 9,220 B.C.E. to 230 CE. Among the many artifacts recovered were fragments of cordage and woven textiles, including petate, basketry, nets, and cloth. The majority of cloth fragments consist of single ply, Z-twist threads of varying thicknesses done in a plain weave. The fibers include cotton and possibly maguey (Agave sp.). The purpose of this presentation is to describe the heretofore overlooked El Gigante textile collection and discuss the possible sources, technology, and use of these fiber artifacts at the site.

Heacock, Erika (Arizona State Museum, University of Arizona) [234] The Repatriation-Process, Conflicts, and Resolutions

Since the Native American Graves Protection and Repatriation Act (NAGPRA) of 1990 was implemented, many museums are looking at their collections to comply with the law. Arizona State Museum (ASM) has taken the task of assembling information on sites in the collections, including the Tucson Basin area, and
other areas, such as the University of Arizona’s Grasshopper Field School that ran from the 1963 to the 1993. Many problems occur when taking on this task, such as identifying all the sites that have human remains and associated objects stored at the museum, formulating the best way to process these materials and projects, assessing the documentation, consulting with interested parties, conducting the actual repatriation, and acquiring funding to cover the process. This poster emphasizes the many issues that occur and the opportunities that arise from the museum’s perspective when acting in accordance with this law, the mitigation of problems, and how to create an organized process or protocol for future repatriations.

Headrick, Annabeth (University of Denver)
[167] Chichen Itza’s Osario: Where Warriors Danced in Paradise
Once considered the mortuary temple of Chichen Itza’s rulers, the Osario has more recently been identified as a Flower Mountain, the celestial paradise of Mesoamerican warriors. However, this identification has remained cursory, relying exclusively on a few visual features. This study will affirm the Osario as a Flower Mountain and the location of elite warrior burials by fully exploring the material and visual remains of the structure. Analysis of charred human remains and their associated artifacts within the cave situated underneath the temple reflects military cremation practices similar to the subsequent Aztec. Likewise, the grave goods associated with a series of burials above the cave are markedly similar to the costume imagery of warriors throughout Chichen Itza. In addition, the stone relief sculpture of the temple, including dancing warriors and a series of four distinct serpents, justify this identification, as they mirror ethnohistoric textual accounts of a valorous warrior’s afterlife. Not only will this study reveal this structure’s function as a vehicle to disseminate the state’s military propaganda through the public celebration of deceased warriors, it will also demonstrate Chichen’s unique appropriation of central Mexican strategies, imagery, and ideologies during a time of great social change in Mesoamerica.

[249] Sourcing and Beyond: Obsidian Use at Two Late Neolithic Sites in Northern Mesopotamia
In this paper we will present the results of our studies of two contemporary but contrasting sites in northern Mesopotamia, Domuztepe and Arpachiyah. Both are pre-urban sites, dating from the sixth millennium B.C., and both may have played the role of central settlements. At both sites obsidian is used extensively for tool manufacture along with flint and additionally for non-utilitarian items which are finished by grinding and polishing. Domuztepe is a large site and obsidian is found in most contexts. Almost 400 artifacts of obsidian, including a variety of non-utilitarian items, have been geochemically analyzed and the data suggests that a wide range of sources (at least nine) are involved although not all were used for the non-utilitarian items. Arpachiyah on the other hand, is a small tell and the majority of the obsidian is concentrated in one place (the ‘Burnt House’). Here the ground and polished items seem to comprise two (or perhaps more) composite objects; most of the debitage was found in the same structure. Our analysis of the obsidians confirms and amplifies Renfrew’s original analysis and indicates that five different sources were exploited, three of which were used for the ground and polished items.

Heaney, Christopher (University of Texas at Austin)
[57] Julio C. Tello and Indigenous Archaeology in Peru and North America
In 1942, a U.S. high school textbook celebrated the Peruvian archaeologist Julio C. Tello (1880-1947) as a “full-blood Quechua Indian.” This paper examines the stakes inherent in the North American celebration of Tello as such, exploring whether Tello’s recognition as one of the Americas’ greatest archaeologists was as much because of his indigenous heritage as in spite of it. Born in a highland Andean community, Tello began his career in Peru at a time of great discrimination towards the country’s indigenous population. As others have argued, he was part of a generation of intellectuals that chipped away at the overt expression of racial prejudice, replacing it—perhaps—with one based on class. Tello’s career, however, was deeply in dialogue with North America and its intellectual climate as well, beginning with his studies at Harvard from 1909-1911. This intervention in the history of archaeology argues that Tello used his indigenous ‘go-between’ status—in Peru, in the U.S., in his highland community—to advance Andean archaeology, as well as his career. In particular, he acted as a gatekeeper for Peru’s indigenous dead, forcing North Americans to recognize and praise his authority and pay increasingly earnest attention to
Peru's asserted ownership of the precolombian past.

Heath, Margaret (Bureau of Land Management)

Past, Present, and Future Directions of Heritage Education

In the United States and Canada heritage education is a young profession, emerging in the 1990s as archaeologists and federal and state agencies realized that reaching out to the public was important for protecting the vast prehistoric and historic resources of the Americas. The major professional archaeological organizations enthusiastically supported their fledgling public education committees and task forces and the SAA in particular provided a large venue for persons interested in practicing heritage education. Archaeologists worldwide explored the concepts of heritage and heritage values. Meanwhile, the expansion of the Internet provided a broad platform for public education as more people had the technological means to access it. After the millennium, the SAA Board began to question the size, independence, and purpose of its Public Education Committee. In 2008, it tasked the PEC with maintaining the SAA "Archaeology for the Public" web page, and it began reducing the size of all committees, requiring long-standing members to rotate off. The unintentional result was that the primary venue for heritage education practitioners disappeared. This paper will explore the past and present state of heritage education, compare it with the development of environmental education, and suggest possible future directions for the profession.

Hechler, Ryan (McGill University)

¡Salud! A Study of Aguardiente in the Western Montaña of Ecuador

Aguardiente is a pure cane-sugar alcohol introduced by the Spanish in the Americas and it spread wherever sugarcane production was present. The production and consumption of aguardiente was an integral part of early Spanish colonial economies in the Americas; the liquor was especially a source of income for lower class distillers whose customers consumed the alcohol socially and even sometimes ritually. With the imposition of colonial government regulation of aguardiente sales in the 18th-century Andes, many entrepreneurs resorted to smuggling the liquor by creating their own trails in the dense jungles of the western montaria of present-day Ecuador or simply appropriating forgotten local indigenous (such as of the Yumbo) and Inka trails to move their products undercover.

Aguardiente distilleries appeared throughout the fertile western montaria of Ecuador and many of these makeshift production centers still exist in the present. This paper is an historical archaeological examination of aguardiente production in the northern Ecuadorian Andes, with a particular focus on the archaeological and architectural remains of distilleries and their associated regional bootlegger trails near present-day Pucayacu, Cotopaxi, Ecuador.

Heckenberger, Michael (University of Florida)

The Measure of Amazonian Complexity

Amazonia has commonly been defined as a world area based on absences of traditional markers of socio-cultural development, such as a lack of productive agricultural systems, domesticated animals, writing, metallurgy, monumental architecture and cities. Recent studies suggest that rather than absent these features exist but in quite different form than other world areas. This paper explores ethnomathematical systems in the southern Amazon, in terms of units of measurement and relationship between elements of the built environment. It argues that pre-Colombian societies had complex relational mathematical systems that were the foundation for large-scale transformations of the natural environment and sophisticated systems of socio-ecological connectivity.

In the Wake of Lord 8 Deer: Postclassic Settlement Changes in the Lower Río Verde Valley of
Coastal Oaxaca
Around A.D. 1100, Lord 8 Deer “Jaguar Claw” established a Mixtec empire in the lower Río Verde Valley of coastal Oaxaca—known as Ñundeui (“Land of the Sky”) by 16th century Mixtecs (Reyes 1593:ii). Lord 8 Deer took advantage of the political instability caused by the collapse of Río Viejo (ca. A.D. 800), the Valley’s capital, to found a new center at Tututepec. Due to an influx of immigrants from the Mixteca Alta, population exploded in the lower Verde. By the Late Postclassic (A.D. 1100-1522), settlement concentration shifted dramatically from the floodplain in the western Valley near the former capital to the eastern piedmont around Tututepec. Areas were inhabited farther away from fertile floodplain lands than ever before, suggesting that political incentives behind settlement choice outweighed ecological concerns. Over the past two years, a continuation of the Valley’s full-coverage survey has shed new light on this phenomenon. This paper discusses Postclassic survey results, focusing on changes in settlement ecology and the political relationship of settlements with Tututepec and the greater Mixteca Alta. We investigate Joyce and colleagues’ (2004) hypothesis that population increases spurred leaders to move settlement off the floodplain in order to free up lands for agricultural production.

Reach 12A Sites and Ritual Deposition in a Regional Context
Data recovery investigations along Reach 12A of the Navajo-Gallup Water Supply Project north of Gallup, New Mexico revealed multiple rich and well-preserved floor assemblages. Complete excavations of two structures -- a Basketmaker III pit structure and a Pueblo II kiva -- exposed numerous discrete deposits, the content and architectural context of which alludes to their purposeful placement, possibly as part of planned ritual closures of associated spaces. The pit structure’s floor assemblage was exceptionally extensive, containing over 150 objects and object clusters including (in varying combinations) projectile points, whole and partial ceramic vessels, cloud blowers, mineral pigments, intact mammal crania, ground stone, polishing stones, and ornaments. This paper examines the social implications of observed depositional patterns, especially the use of specific objects and object associations, a number of which have analogs among ethnographically known ritual paraphernalia. The findings from Reach 12A are contextualized using ethnohistorical accounts and archaeological documentation of floor assemblages from excavated structures in the San Juan Basin and beyond.

Heep, Nathan (University of Texas at San Antonio) and Whitney Lytle (University of Texas at San Antonio)

Archaeology, Public Outreach, and the University
The benefits of outreach programs have been demonstrated to be multifold. Archaeology education and outreach can benefit grade school students by offering the opportunity to reinforce required curriculum with a unique hands-on approach. Community education also encourages respect and preservation of the archaeological record. As part of a university’s anthropology department, these programs can offer much more than grade school community outreach. Volunteer opportunities allow undergraduate and graduate students to add stock to their resumes while gaining valuable experience learning effective techniques to disseminate archaeological knowledge. Additionally, by acting as another educational resource where students enhance their own pedagogical methods, the outreach program reinforces their significance to the university. The Center for Archaeological Research at the University of Texas San Antonio offers these opportunities to students through their "LEGACY: Hands on the Past" outreach program. If education is considered the goal, then outreach can be seen as the method to reach this goal. Expanding public outreach goals to include both the public and student educators, the program creates a richer edifying environment. This paper will present the strategies utilized by the LEGACY outreach program to benefit the community and the university while enhancing the preservation of the archaeological record.

Heffter, Eric (The University of Arizona) and Kele Missal (The University of Minnesota)

Absolute Beginners: Indicators of Knapping Expertise in Simple Technologies
It is well known that the task of flintknapping requires time and some level of skill to properly execute. Several authors (summarized in Bamforth and Finlay 2008) have hypothesized that certain flake attributes are indicative of skill. Unfortunately, few researchers have attempted to confirm these
hypothesized markers of proficiency. Our experiment tests which flake attributes are indicative of expertise by comparing the debitage produced by 37 novice and 4 expert knappers during a simple flake removal exercise. While some novices were able to produce flakes comparable in size to expert knappers, aggregate data confirms that there are significant differences between novices and experts for several flake variables, including weight, size and platform type. Many other flake characteristics thought to indicate skill (such as termination type) were not significantly different between the two groups. The experimental results from this robust data set can help archaeologists understand the ways in which knapping expertise influences flake morphology and which flake attributes can aid in identifying episodes of novice knapping in the archaeological record.

Hegmon, Michelle (Arizona State University), Will Russell (Arizona State University), James McGrath (Arizona State University) and Michael O'Hara (Arizona State University) [66] Mimbres Pottery Designs in Social Context

In order to record and study the spectacular designs on Mimbres pottery, Steven LeBlanc and the Mimbres Foundation created the invaluable Mimbres Archive, a collection of photographs of Mimbres vessels. The Archive was the basis of the much larger recently created Mimbres Pottery Images Digital Database (MimPIDD), which facilities systematic analysis of the designs. Using data from MimPIDD this paper investigates the social significance of the pottery designs through spatial analyses of several design dimensions. Specifically, we classify the designs based on attributes normally considered by archaeologists (design layout and animal taxon) as well as attributes suggested by Southwestern and Mesoamerican indigenous sources, including folk-tales, cosmologies, traditional histories, and traditional ecological knowledge. These sources categorize animals according to appearance, habitat, clan affiliation, relation to humans, and other characteristics (e.g., elders, tricksters). We then consider the spatial distribution—at both inter- and intrasite levels—of those various dimensions, using a sample of over 4,000 provenienced vessels. Results reveal whether and how animal designs were used to mark social distinctions, and which dimensions of the designs were socially significant.

Heide, Poul (The Archipelago Museum of Southern Denmark) [29] Tying Precious Knots: The Resilience of Communication Systems in the North Atlantic Landscapes during the Transatlantic Migration in the Viking and Middle Ages

Establishing and maintaining communication systems is a crucial task to any society. ‘Communication’ can be as important as any other resource, not least to explorers and settlers. In this presentation I will discuss what my recent research has shown about how the communication systems were established and transformed during the Viking Age Transatlantic migration.

The natural conditions of the North Atlantic landscapes put any communication system under stress, even today. Whether we look into communication between new islands and homelands or the communication systems within the individual settlements, we see how it became harder and harder to maintain standards the further people move westward. Resilience of communication is the resilience of a system of habits and techniques. Communication systems are generally prone to immediate adaptation, and through the study of communication systems we get to discuss a social perspective on climatic changes that affected the ancient North Atlantic world.

The thirteenth century was an extremely volatile period in northern Europe. I discuss the specifics of the North Atlantic communication systems drawing on observations from Scandinavia, where both political, economic and technological developments were of such magnitude that they altered conditions for communication all the way out into the North Atlantic.

Heilen, Michael (Statistical Research, Inc.) and Phillip Leckman (Statistical Research, Inc.) [294] Cultural Landscapes of the Chuska Valley, New Mexico

In this paper, we examine cultural landscapes of the Chuska Valley, in northwestern New Mexico, through the concepts of persistent place and persistent community. Using data on more than 6000 sites recorded in the New Mexico Cultural Resources Information System, variation across time and space in
Archaic and Anasazi settlement location, clustering, intervisibility, and function is analyzed to identify where persistent places and communities emerged and to interpret long-term patterns of regional occupation and abandonment. Particular attention is paid to understanding potential relationships among sites, including the role that sites with integrative structures—such as plazas, great kivas, or great houses—likely played in influencing the organization of settlement across the landscape. The ways in which environmental and cultural factors may have affected the formation and abandonment of persistent places and communities are also considered.

Heins, Sarah

[113] Craft Bone Toolmaking at Post-Classic Mayapán

Recent studies have examined the integration of animal resources into crafting production at the household and community level economies of the ancient Maya. White-tailed deer (Odocoileus virginianus), in particular, was relied on heavily by Post-classic Maya based on their presence in high frequencies in mainland faunal assemblages. Bones of white-tailed deer are found in elite and non-elite dwellings, in ritual contexts, and in crafting contexts thus indicating their economic versatility. Some researchers suggest that the Maya may have been managing deer populations which would have provided a constant supply of deer to Maya communities. This study explores the extensive bone fragmentation of white-tailed deer remains and the bone tools found at Mayapán, a Post-classic Maya urban center on the Yucatán peninsula in Mexico. High frequencies of cultural breakage, differential skeletal element representation, and large numbers of bone tools suggest that much fragmentation at crafting houses is linked to bone tool manufacture and use. The spatial distribution of differentially fragmented bone assemblages reveals differences in activities of crafting houses and other dwellings. Formal and informal bone tools contributed significantly to the manufacture of other craft items, including textile embellishment.

Heisinger, Bryan (Gault School of Archaeological Research) and Anna Gilmer (Gault School of Archaeological Research)

[318] Fluvial Gradient Profile and Sedimentation at Gault Site, Texas

At the Gault site (41BL323) long term fluvial sedimentation in Buttermilk Creek Valley is inconsistent among low order streams of the Central Texas region. In first and second order stream valleys across the southern plains periphery it is uncommon to find surviving deposits that are older than early Holocene, but at Gault there are extensive Late Pleistocene alluvial deposits dating from at least 27,000 BP. A slight but distinctive reduction in the longitudinal gradient profile of Buttermilk Creek is the apparent explanation both theoretically and from observed patterns of deposition during recent flood events.

Heitman, Carrie (University of Nebraska-Lincoln)

[333] Layered with Meaning: Mediating Social Integration through Architecture in Chaco Canyon

My paper in this session addresses the question of how architecture served to mediate social integration during the Bonito Phase (A.D. 850-1150) occupations of Chaco Canyon, New Mexico. Taking a broad view of “public architecture,” I look at the practices by which built spaces were invested and layered with meaning through a shared language of religious symbols and ritual deposits. After outlining these patterns, I discuss the social processes that may have surrounded the use of these architectural investments and their role in both integrating groups of people at various scales and magnifying social inequalities over time.

Heller, Eric (University of California Riverside)

[37] A Practice of Polity: Demarcating Ideational Boundaries in the Classic Period Maya Lowlands

Foundation to identity, social relations, and the operation of political authority, practices related to the production and construction of community and polity boundaries are well documented via ethnographic and ethnohistoric sources in Mesoamerica. Increasingly, scholars are linking modern and historical practices to more ancient archaeological materials, extending practices of community demarcation deep into the Classic period in the Maya region. Using the ancient Maya site of La Milpa, northwestern Belize, as a case study, this paper examines several possible examples of spatial delineation on community and polity scales through attention to the arrangement of architectural features and monuments on the landscape. Employing a comparative lens that considers modern practices alongside ancient examples of boundary making and marking, this paper evaluates the extension of ethnographic and ethnohistoric practices into antiquity, raises the possibility that several polities within the Maya Lowlands shared and replicated concepts of an idealized city image, and explores the potential for disjunction between material
demarcations of ideational borders and patterns of settlement shaped by the realities of praxis.

[245] Preliminary Research at Samanco: An Early Horizon Seaside Center of the Nepeña Valley, North-Central Peru

Over the past decade, significant research has been conducted in the Nepeña Valley regarding 1st millennium B.C. coastal societies. Yet numerous questions remain regarding the role of maritime communities during a time period when inland developments are frequently emphasized. In 2012 and 2013 field operations were carried out at Samanco, one of the largest Early Horizon Nepeña sites, located adjacent to the rich Samanco Bay. Mapping data revealed a site core spanning over 30 hectares, comprised of dense quadrangular stone architecture organized into distinct compounds. Excavations confirmed Samanco’s Early Horizon occupation, and provide preliminary insights into the site’s identity as a focal point for maritime interactions with inland centers as well as a fully functioning, semi-autonomous residential center. This paper examines the preliminary data from Samanco which frame working hypotheses about Early Horizon economic networks and urban transformations.

Helmke, Christophe (University of Copenhagen)
[33] Speleothem Monuments at Yaxchilan, Mexico

Over the past two decades it has become increasingly clear that speleothems occupied a privileged position in ancient Maya culture. James Brady has been instrumental in drawing the attention of his colleagues to archaeological examples of flowstone and dripstone formations, such as stalactites and stalagmites, which were subjected to deliberate breakage and removal. Although the motivations behind these actions are still unclear, instances are known wherein large columnar speleothems were erected as monolithic monuments. The archaeological site of Yaxchilan, in present-day Mexico, provides several key examples of this practice. One such speleothem monument—designated as Stela 31—was carved with an elaborate iconographic program and a series of glyphic captions. This specimen demonstrates the importance of speleothems in royal rituals and reveals that erected speleothems, on par with conventional stelae, could serve to commemorate rites performed at important calendrical stations.

Helton, Erin (Versar/GMI) and Christopher Goodmaster (Versar/GMI)
[199] Geospatial Analysis and Landscape Archaeology in the Lower Pecos Canyonlands

Spatial analysis is useful in painting a holistic picture of a cultural landscape as it allows for synthesis between otherwise isolated collections of data. With renewed interest in archaeological field research conducted in the Lower Pecos Canyonlands, it is important to shift the focus of archaeological research from a site-specific scale to consider the cultural landscape as a whole. Observing archaeological data at a regional level can help researchers better understand the relationship between native groups and how they utilized their environment over time and space. Within a robust GIS framework, data can be presented in spatially meaningful ways, revealing patterns or trends that may not have otherwise been detectable. This presentation will discuss findings from spatial analyses conducted on archaeological site distributions in the Lower Pecos Canyonlands. Spatial analysis techniques include 3D terrain modeling, viewshed analysis and visibility, cost-path analysis, and distribution analysis of sites to other known resources.

Hemingway, Katharina (University of Denver, Department of Anthropology) and Lawrence Conyers (University of Denver, Department of Anthropology)
[196] Ground-penetrating Radar Efficacy for Mapping Graves in Variable Ground Conditions

Ground-penetrating radar is an especially effective geophysical method for locating and studying graves of many different ages and types, in wide varieties of sediments, soils and environmental conditions. In formal and informal cemeteries the overburden mineralogy and moisture is the most important variable affecting resolution. Electrically resistive ground such as sandy sediment is optimum, but even good results have been obtained from ancient Medieval English cemeteries in wet clay ground if amplitude analysis and frequency filtering is used. Roman burials in crypts and vaults are easily mapped in three-
dimensions in sandy or limestone ground. Frontier USA graves composed of deteriorated wooden coffins are particularly challenging due to the plethora of reflections from the remaining features. Informal Australian Aborigine graves can be differentiated from European internments based on their orientation, associated grave goods and depth of burial. In a formal California cemetery where all burial took place at the same depth, with the same burial features, the highly variable overburden chemistry produced extremely complex GPR images, with large changes in apparent depth and resolution. These could be predicted if the ground was studied in detail during processing. GPR is the highest resolution method for mapping graves due to its three-dimensional capabilities.

Henderson, A. Gwynn (Kentucky Archaeological Survey)
[96] Public Archaeology at the Kentucky Archaeological Survey
With the creation of the Kentucky Archaeological Survey in 1996, the Kentucky Heritage Council (SHPO) and the University of Kentucky’s Department of Anthropology initiated a state-wide proactive public archaeology program. In addition to providing students and the public with hands-on archaeological experiences, KAS has partnered with others to develop diverse educational programs and a variety of educational materials, including curriculum, lesson plans, booklets, webpages, and videos. Of particular importance has been an ongoing evaluation and assessment of program effectiveness, and the publication of these findings. KAS continues to develop public archaeology programs and to pursue research in this venue as part of its commitment to professionalizing heritage education.

Henderson, Lucia (The University of Texas at Austin) and Barbara Arroyo (Proyecto Kaminaljuyu, IDAEH)
[120] The Life Aquatic: The Archaeology and Iconography of Water at Kaminaljuyú, Guatemala
Although Guatemala City’s urban sprawl has destroyed much of Late Preclassic Kaminaljuyú, the remains of this early site nevertheless speak eloquently about the ideological, political, economic, and religious importance of water. Constructions within and beyond the city center demonstrate that enormous efforts were made to channel, direct, and utilize water at Kaminaljuyú. Stone sculptures reveal that multiple deities governed water at Kaminaljuyú and were used in art to legitimize the reigns of early rulers. In this paper, the authors integrate recent archaeological discoveries with iconographic analysis, investigating the hydraulic infrastructure of Kaminaljuyú and the interconnected movements of human bodies, sculpture, and water through the site’s built and natural environment.

Hendon, Julia (Gettysburg College)
[161] Traces of Local Histories in the Landscape of the Lower Ulúa Valley Then and Now: Multiple Perspectives on the Intersection of Past and Present
People have lived in the Lower Ulúa River Valley in Honduras for over 4000 years. We explore processes of place-making and landscape creation at several different times in the valley’s occupation. We focus on the people who lived in the valley at these different moments in its history as communities of practice, each bound together by shared sets of practices and relationships. This approach allows us to consider the connection between practice and meaning, landscape and history, daily life and ritual cycles, and social relations and economic ties without entangling us in claims about cultural continuity or rupture. In addition to data derived from archaeological research in the valley at such sites as Cerro Palenque, Currusté, and others, we also draw on ethnographic research and the educational outreach programs sponsored by the Instituto Hondureño de Antropología e Historia under its former gerente, Dario Euraque. We discuss the multiple ways that the valley’s residents incorporated the past into their present-day experience. Although the specific meanings may differ and the kinds of places created may vary, we argue that one thing that links together our examples is the importance of local histories grounded in a particular social and physical setting.

[159] Negotiating Historicism and Ritual Action: Assessing Dualistic Space at the Mount Horeb Earthwork Complex in Central Kentucky.
Middle Woodland earthwork complexes are prominent in Eastern Woodlands research. Nevertheless, we have numerous chronological voids in Woodland research on ritual landscapes. The Mount Horeb complex is a unique collection of earthworks in the Central Kentucky Bluegrass region, long considered important to social interpretations for Ohio Valley Woodland societies. However, the sequence of landscape evolution at this complex has never been investigated. Recent research at multiple earthworks in this complex allow for a fresh contextualization of geometric and irregular earthen enclosures. Using new data, historical understandings of landscape and ritual transformation—possibly grounded in social duality—are explored.

La Consentida and Initial Early Formative Period Social Organization on the Pacific Coast of Oaxaca, Mexico

Investigations between 2008 and 2012 at the archaeological site of La Consentida have produced evidence for the transition to domestic sedentism, social complexity, the adoption of an agricultural economy, and exchange of ceramic iconography during the Early Formative period (1900-850 B.C.) in coastal Oaxaca, Mexico. This presentation provides a summary of field and laboratory research phases of the La Consentida Archaeological Project, including site mapping, excavations, and analyses of artifacts and samples. Information regarding architectural stratigraphy, funerary practices, ceramic vessel styles, stone tools, and ceramic iconography indicate that La Consentida participated in the fundamental social reorganization of the Early Formative. Based on several radiocarbon dates from secure contexts, La Consentida has produced some of the earliest ceramics, mounded earthen architecture, and musical instruments thus far identified in Mesoamerica. Data from obsidian sourcing and the comparison of iconographic styles of decorated ceramics and other small-scale artifacts indicate La Consentida’s participation in broad spheres of early Mesoamerican interaction. Examples of these networks include ceramic iconography indicative of contacts with West Mexico and obsidian from central and Gulf coastal Mexico. These results will help to redefine the role of the Oaxacan coast in the critical social transformations of Early Formative Mesoamerica.

Why We Tell Them We're Divorced: When Local Expectations Clash with our Roles as Researchers

Fieldwork requires the archaeologist to engage with local communities on a variety of levels, many of which have little to do with the interests of the community or the aims of our projects. Often well-trained in theory and methodology but less prepared for the ethnographic reality of fieldwork, archaeologists who do not easily meet local expectations have historically navigated local conditions individually and on an ad hoc basis. In particular, community expectations of performed femininity can be in direct conflict with methodological expectations of performed archaeology. This paper presents a framework for the training
of archaeologists equipped to meet such challenges in ethical, culturally sensitive, and methodologically sound ways.

[242] Atoll Archaeology: A Summary Report of Archaeological Surveys at Rose and Swains Islands, American Samoa

This paper presents preliminary results of the 2012 and 2013 archaeological field seasons at Rose and Swains Island, American Samoa. Until this project, very little archaeological documentation had been undertaken on these outlying islands. Discussion of the results from the Swains Island project include the description of limited subsurface testing, as well as the identification of historic properties including, but not limited, to a historic church (ca. 1886), historic cemeteries, a cut beach rock pathway, and a traditional pre-European tupua. Survey results on Rose Island identified historic properties ranging from a U.S Naval Administration historic monument placed on the atoll in 1920 by Governor Warren J. Terhune to a fale foundation which is likely a residential structure associated with a 19th century German copra plantation. Additionally, basalt flakes, a basalt stone, and water worn basalt pebbles were discovered and collected. Some of the basalt collected was submitted for X-Ray Fluorescence (XRF) analysis. The elemental concentration data was analyzed to determine local or exotic provenance, and will be discussed in relation to other known basalt sources in Western Polynesia.

[189] Reflections on the Use of Full-Coverage Archaeological Survey in the Tequila Valleys of Jalisco, Mexico

A reassessment of the unsystematic surveys carried out in the Tequila Valleys between the 1960s and 1980s shows that pedestrian, regional, and systematic full-coverage survey is the best and most effective method for recovering large amounts of high quality data to solve anthropological questions at the regional scale. In the past six years, we have applied this methodology to the Tequila valleys of Jalisco, concentrating efforts in the valleys north of the Tequila volcano and, most recently, in the Magdalena Lake Basin. To date, we have recorded hundreds of sites some of which were known from past surveys, but many were not. However, in some cases we were unable to relocate previously identified sites for myriad reasons, including postdepositional factors. Yet, our surveys also demonstrate that large settlements without monumental architecture (especially Epiclassic and Postclassic sites) were ignored in favor of flashy places such as shaft tombs and guachimontones. Consequently, the data collected by our recent surveys provides a corrective to the biased view of the current Tequila valleys regional archaeological sequence.

Herlich, Jessica (College of William and Mary)

[125] The Kiskiak Site and Paleoethnobotany: A Multi-linear Approach to Environmental and Social Dynamics in Tidewater Virginia

Kiskiak is a multi-site area within the Naval Weapons Station Yorktown (NWSY) concentrated in the area of Indian Field Creek. It is compelling in Tidewater Virginia for its deep breadth of time and diversity of features, presenting facets of past Algonquian landscapes. From the Late Archaic period (ca 1300 B.C.) to the Early Colonial era (ca AD 1600), Kiskiak is a long term example of Algonquian peoples revisiting and settling coastal localities. The College of William and Mary’s excavations at Kiskiak are exploring how Kiskiak fits into the greater Chesapeake archaeological and historical past. This paper will discuss my dissertation’s focus on human-environmental dynamics at Kiskiak through a multi-linear paleoethnobotanical approach. Through macrobotanical remains, phytoliths, starch grains, and artifact data, this paper explores landscape and related changes in coastal hunter-gatherer and forager subsistence practices, use of natural resources, and labor divisions at Kiskiak. These various analyses indicate complex uses of space and changing human-environmental relationships over time at Kiskiak, which have intriguing implications for how coastal sites fit into conversations pertaining to tradition, movement, exchange, and subsistence in the Chesapeake.

Hermes, Taylor (University of Arizona / Russian Institute of Archaeology, Novosibirsk)

[20] Our Complexity Against Theirs: Neolithic Cultures in the Altai Mountains
This paper explores the transition to pastoralism in the Russian Altai Mountains through the cultural variability and interaction of autochthonous Neolithic populations. Unlike theories based in long-distant, permanent migrations, I argue that early pastoralism in this region is a social development rooted in the dynamics of pre-existing communities of hunter-gatherers. These groups in the Altai and adjacent regions have been unjustly overlooked by many archaeologists writing about transformative changes across Eurasian landscapes. Regardless of the geographic vector that domesticated animals and the knowledge to organize life around them was carried, Neolithic communities who foraged in the ecosystems of the Altai played a defining role in how culture change unfolded. I draw upon complexity science and network theory to suggest that local actors of the Altaic Neolithic mediated the receipt of new ways of living against their existing cultural logics. In this approach, subsistence change and concomitant cultural developments are byproducts of local systems fraught with histories of resilience, who differentially adopted pastoral subsistence but led to the seemingly uniform emergence of the region's first food producing societies.

Hernandez, Hector (Universidad Autonoma de Yucatan)

[72] Technological Change of Henequen Desfibradora Machine during Yucatan’s Gilded Age

Archaeologists conceive of technological change as a process that involves the transition of a certain technology through different stages, such as invention, development, manufacture, adoption, and abandonment. In this paper I discuss the technological change of the fiber processing machines that were invented during the first half of the nineteenth century in the Yucatan peninsula. The adoption and spread of the desfibradora machine was a key factor that influenced the growth of henequen production on haciendas and paved the way for other technological developments during Yucatan’s gilded age. My goal is to analyze the processes of invention, adoption and abandonment of the henequen processing machines based on documents, photographs and archaeological evidence recovered from haciendas in northern Yucatan. Finally, I consider how the technological development encouraged by Yucatan’s hacienda owners was part of a social process that brought different consequences to the peninsula’s native communities at the dawn of the modern era.

[254] Settling the Ucareo Valley: Early Classic Relationships between northeastern Michoacán, Mexico and the Eastern El Bajío

The legacy of Dan Healan’s ongoing work at the site of Tula in southern Hidalgo is well known and much celebrated. However, the impact of his investigations in the Ucareo-Zinapécuaro Obsidian Source Area (commonly referred to as the UZ source area) in northeastern Michoacán has yet to be fully appreciated. The UZ source area is perhaps best recognized as that corner of the Protohistoric Tarascan-Aztec frontier where Tarascan (Puréhpecha) led forces repeatedly defeated Aztec troops and successfully kept Mexican expansion further into the West at bay. The results of ceramic and chronometric analysis of data recovered by Dan’s Ucareo-Zinapécuaro Project (1989-1995) suggest that the cessation of friendly relations with Mexico was a very recent reversal of a longstanding history of strong cultural and economic ties between NE Michoacán and its neighbors to the east. Ceramics from sites in the southern Ucareo Valley reveal a split in the cultural trajectory of settlement in the UZ source area beginning in the Early Classic period (A.D. 200- 400). The implications for the role of early obsidian exploitation are considered as are relationships with a proposed Teotihuacan enclave at el Rosario in southern Querétaro.

Hernandez, Amanda (Crow Canyon Archaeological Center)

[268] Optimal Geophysical Methods for the Location and Identification of Basketmaker III Sites in Southwestern Colorado

This study will discuss the use of optimal geophysical techniques to assist in locating and identifying Basketmaker III sites (A.D. 500 – 750) in the Ancestral Puebloan region of Southwestern Colorado. The National Historic Preservation Act mandates evaluating these sites for their potential to provide information important in understanding prehistoric behavior. Since most archaeological investigations (surveys, testing projects, and data recovery) to discover and evaluate sites, are time sensitive and constrained by budgets, it is imperative that geophysical methods, which are both time and cost efficient, are integrated into research. The buried structures and features that comprise Basketmaker III sites are
often imperceptible from the surface, making the use of geophysical methods invaluable for their location and evaluation. This study is a synthesis of research and geophysical survey results coupled with ground truthing of anomalies to locate and identify a small number of Basketmaker III sites on the Indian Camp Ranch subdivision in Cortez, Colorado. Geophysical explorations on this property have included magnetic gradient survey, electrical resistivity, electrical conductivity, and ground penetrating radar. This study will contribute to understandings of Baketmaker III period site structure in southwestern Colorado by elucidating patterns in site size, layout, and location on the landscape.

Hernández Escontrías, Pilar (Northwestern University), Claudia Núñez Flores (Pontificia Universidad Católica del Perú) and Sofía Chacaltana (University of Illinois at Chicago) [256] Contested Space, Contested Bodies: an Archaeological Assessment of Indigeneity, Hispaneness, and the Conflicts of Spanish Colonial Governance in Peru

We argue that in order to understand the mechanisms of colonial governance, we must analyze how the differential manipulation of spaces served as a tool of hegemony. We consider the visual and temporal relationship between two colonial-period settlements in Moquegua: Torata Alta, a colonial reduction, and Sabaya, an Inka and colonial site. Torata Alta, a symbol of Spanish control over indigenous bodies, overlooks Sabaya, an important Inka settlement in the upper Moquegua valley. Despite its visual domination over the valley, Torata Alta (the most “Spanish”) did not survive as long as the more “Inka” site, Sabaya. Indeed, the site that was most successful at withstanding the test of time was the presumably more indigenous site, containing the characteristically Inka architecture. In this study, we use archaeological data to compare everyday life under two seemingly contradictory colonial gazes. We argue that, within the same valley, Spanish governance was not monolithic, resulting in differing lived experiences between the inhabitants of Sabaya and Torata Alta. By engaging in this comparison, we dismantle the heuristic boundaries existent between “indigenous” and “Spanish,” and regard colonialism as a dialectical process, whereby the indigenous become hispanicized and the Spanish became indigenized.

Hernandez Garavito, Carla (Vanderbilt University) [256] Colonialism and the Construction of Community: The Case of Huarochirí in the Central Andes (Lima, Peru)

Colonial Power in the Andes was constantly constituted, redefined, and negotiated, as different interests came into contact. Colonialism is built at the same time that it is experienced, leaving ample space for ambiguity and reconstitution of identity. In this presentation, I seek to explore the role colonialism played in constructing a sense of community and a shared memory through historical and archaeological evidence in the Central Andes. My main focus will be in the region of Huarochirí (Lima, Peru). Archaeological research provides clues to the impact Inka expansion (1440-1532 A.D.) had over the area, as they facilitated community formation at the same time that they made Huarochirí legible to the Empire by appropriating community memory. Later, Spanish colonialism created the conditions for a reenactment and recording of this order: the Huarochirí Manuscript, an early 16h century document written in quechua and filled with myths and rituals still practiced in the early colony, will provide an important backdrop to understanding how these communities conceived of themselves through time. I argue that community and identity were main variables in the constitution of colonial order, both creating and negotiating the ambiguous spaces generated by the process itself.

Herndon, Kelsey (The University of Alabama), Brett A. Houk (Texas Tech University), Mark Willis and Chester P. Walker [107] The Structure from Motion Solution: Mapping Structure A-5 at Chan Chich, Belize

In 2013 the Chan Chich Archaeological Project conducted photogrammetric mapping and excavations on
Structure A-5, a large range building in the Main Plaza at the ancient Maya site of Chan Chich, Belize. Prior to excavations, the project created a digital elevation model of the mound using pole aerial photography (PAP) and Structure from Motion (SfM) software. During excavations, archaeologists photographed each exposed architectural feature extensively and uploaded the images to an analyst who created photogrammetric blocks of the excavation units using the same SfM software. The photogrammetric mapping technique proved tremendously effective. At the structure level, the PAP system used for collecting data proved efficient and cost effective. In fact, we believe that the resolution and accuracy of the SfM technique is comparable to using a 3D laser scanner, but can be accomplished for a fraction of the cost. Additionally, the SfM system, when used to record individual excavation units, can replace the traditional system of drawing plan maps and profiles. Furthermore, this method allows researchers to present data in an interactive way through 3D models that can be viewed via a variety of digital platforms.

[34] Current Efforts at Defining Isthmo-Colombian Settlement Ecology
Recent investigations into prehispanic settlements in southern Costa Rica are providing new evidence of variation among local traditions dating back to the Aguas Buenas period (300 B.C.-A.D. 800). Differences between built environments in the area, which range from mortuary villages to possible ceremonial seats of centralized leaders, seem to suggest different social configurations within different groups, despite the relatively close proximity of these different communities. Although site attributes can be broadly identified as part of greater Chiriquí culture, the apparent heterogeneity of settlement patterns raises important questions such as how local traditions emerged and to what degree these practices interacted with and influenced each other. Data obtained from the site of El Cholo are used as points of comparison to evaluate how settlements and communities located close to each other could have adopted such varying social dynamics.

[41] Local and Imperial Dynamics in a Residential Neighborhood at Assyrian Sam'al (Zincirli, Turkey)
Household archaeology has transformed the study of ancient empires in the past two decades, turning these quintessential juggernauts upside-down by the addition of peripheral and quotidian voices and fine temporal and spatial scales. In this paper, this local perspective is trained on the Neo-Assyrian empire through analysis of the development of a residential neighborhood at Sam'al (modern Zincirli, Turkey) across its transition from local center to peripheral provincial capital in the late 8th century B.C. Archaeological evidence for agricultural and craft production, consumption of goods and resources, and social organization in this neighborhood is compared over successive phases of occupation. This analysis reveals striking continuities that indicate minimal direct Assyrian interference into provincial economic and social systems, supporting the view that imperial goals were limited to military control and defense in this already developed peripheral area. However, subtler shifts in local economic activities and social patterns can be attributed to the unintended consequences of the empire’s unprecedented territorial unification and centralization, in combination with purely local dynamics. This study of the Assyrian impact from the perspective of household archaeology on the periphery complements and complicates previous studies based on large-scale settlement patterns or documents from the imperial center.

Herrmann, Jason (Dartmouth College)
Ground-based remote sensing and three-dimensional visualization techniques have reinvigorated research on the interior structure of earthen mounds in the US Midwest as they provide a method for observing subsurface mound deposits without disturbing sensitive mortuary remains.
Archaeologists at the Center for American Archaeology in Kampsville, Illinois are documenting the internal structure of a variety of Middle and Late Woodland earthen mounds in the Lower Illinois River Valley to explore the benefits and limitations of the use of geophysical methods in mapping key mound elements. As part of this study, both large earthen mounds in the valley bottom, as well as burial tumuli along the valley bluffs, have been sampled with ground-penetrating radar (GPR) and electrical resistance tomography (ERT), each of which presents distinct advantages and drawbacks. The results of these remote sensing surveys confirm some prior interpretations of mound structure that were built on test excavations that can be extrapolated laterally across mound deposits in three-dimensional visualizations. Elements of mound structure that were not previously documented have also been identified. Finally, these surveys have proven to be an effective means trace the slow destruction of these structures as they succumb to natural and anthropogenic erosion.

Mortuary Variability in the Late Woodland to Early Mississippian Period in the Lower Mississippi Valley and Central Gulf Coast: A View from Morton Shell Mound

Mortuary facilities in the Lower Mississippi Valley from the Late Woodland to Mississippian Periods often present complex deposits resulting from varied burial treatments. One such facility is the Morton Shell Mound (16IB3), which represents a prehistoric settlement as well as a mortuary facility on the central Gulf Coast. The mound is a continuous shell deposit with several elevated mounds. The northwest mound, designated Mound B, contains a burial deposit likely associated with the Coles Creek to Plaquemine period of the Lower Mississippi Valley. The burial deposit is comprised of commingled remains and primary interments. Recent research has focused on an evaluation of the human remains in an attempt to decipher the sample demographics and health, body processing, burial treatment, and the depositional history of the mortuary facility. To address these issues we examine skeletal and dental pathologies, visualize skeletal and pathology spatial distribution, assess bone fracture patterns, perform intensive refitting, and analyze various quantitative measures using a three-dimensional surface fitting method to derive metrics. Through these multiple lines of evidence, we examine the mortuary behaviors and identity at Morton, relative to earlier Tchefuncte and Marksville, as well as contemporaneous Coles Creek and Plaquemine mortuary sites of the Lower Mississippi Valley.

Hester, Thomas (Emeritus) and Harry Shafer (Prof. of Anthropology, Emeritus Texas A&M University)

Late Preclassic Complexity: Views from Colha

We have documented in numerous papers the rapid expansion of stone-tool production in the Late Preclassic at Colha, Belize. We developed a “producer-consumer” model to illustrate the distribution of stone tools to other communities in the region. However, there are several other facets of the site’s socioeconomic complexity that have received less attention. Among these is the manufacture of lithic symbols (“eccentrics”) both for local ritual use, and for the elite’s use at other sites. Still another example is linked to the significance of persons who functioned as flintknappers at the site, and their involvement in ceremonial rituals. Economic data demonstrate change in faunal use from Middle Preclassic into the Late Preclassic. Our colleague, Leslie Shaw, examined the Late Preclassic animal bones for her dissertation, and the data she obtained are important in the study of complexity at Colha. The changes in dietary data may reflect interaction between Colha and its neighbors.

Skútustaðir: Considering an Icelandic Farm Across Scales

Skútustaðir has been a socially and spatially central farm in Mývatn, N. Iceland, perhaps since the middle ages (1000-1550 C.E.), though it was settled in the Viking age (871-1000 C.E.). Seasonally scheduled production at the farm combined the husbandry of domesticated mammals, collection of wild bird eggs,
fishing, and the movement of resources in from the coast, 60 km to the north. Using zooarchaeological evidence from this specific farm, the present work describes the particular strategies of resource use in the middle ages. Its production, ecology, and social life are described relative to the large-scale narratives in Icelandic history of that period.

Hicks, John (Univ. of Illinois at Chicago/The Field Museum) [298] Portable X-Ray Fluorescence (pXRF) Analysis of Lithic Materials from Easter Island (Rapa Nui)

This poster presents a geochemical analysis of lithic samples from prehistorically-utilized material sources on Easter Island (Rapa Nui), including obsidian, scoria, and volcanic tuff. Analysis was conducted using portable X-Ray Fluorescence (pXRF), which has not been used on Easter Island but is known to be effective in the Western Pacific. The analytical dataset consists exclusively of non-archaeological samples collected through raw-material survey; earlier studies have relied primarily on stone tools from archaeological contexts. The study had three objectives: (1) identify elements or element combinations indicative of provenance using samples from geologic sources; (2) determine if uncommonly-analyzed lithic materials—tuff and scoria—can generate meaningful data; and (3) compare the results of pXRF analysis to other, more sensitive techniques like PIXE-PIGME or TOF-LA-ICP-MS. Results of statistical analyses (e.g., PCA, DFA, and ANOVA) show that pXRF effectively discriminated between materials sources for all materials. Key diagnostic elements were Ti, Fe, and to a lesser extent Ca and Zr.

Higelin, Ricardo (IU) and Gonzalo Sanchez Santiago (UNAM) [293] The Omichicahuaztli (Scraper Bone as Musical Instrument) in Southern Mesoamerica: A Multiple-Method Approach to Interpreting Their Use and Significance among Prehispanic Cultures of Oaxaca

We analyze a set of relatively rare artifacts made out of human and animal bone found in different archaeological sites in Oaxaca, Mexico. To make these artifacts, people carved the diaphyses (shafts) of relatively flat long bones with a series of transverse notches, sometimes adding perforations within the notch to produce a musical instrument. Based on ethnohistorical accounts, such instruments are identified Omichicahuaztli, a Nahua language term translated as “scraper bones.” Given the frequent association of Omichicahuaztli within mortuary contexts, these artifacts may have been used as musical instruments associated with funeral ceremonies and ritual practices. In this paper, we examine the archaeological contexts in which Omichicahuaztli have been recovered, review examples of artifacts made out of human and animal femora found in other parts of Mesoamerica, identify the kinds of bones out of which Omichicahuaztli are constructed, and provide an organological description of the resulting musical instruments in order to try to better interpret meaning and use of Omichicahuaztli in Oaxaca and greater Mesoamerica.

Higgins, Howard (TRC Environmental Corp.) [50] Ethnological and Archaeological Inventory with the Mescalero Apache Tribe of Potential Traditional Cultural Properties in the Permian Basin MOA Area, New Mexico

In 2010, the Bureau of Land Management, in cooperation with the Mescalero Apache tribe, selected nine locations in Eddy County, New Mexico, for archaeological and ethnological inventory as potential Traditional Cultural Properties (TCPs). This paper reports on how this study was conducted and its results. Each of the nine locations was visited at least once by a team consisting of an ethnologist, an archaeologist, and tribal members. During these visits, each location was evaluated as to presence or absence of characteristics that would justify its recommendation to the NRHP as a TCP or sacred site. Among others, these characteristics included physiographic elements; local historic events; and the presence of rock art, Native American structural remains, and resources important in the practice of Mescalero culture. Subsequently, five of the locations were recommended as eligible for the NRHP and two were not. The remaining two could not be evaluated due to the limited amount of work at each of these locations and the resulting paucity of information. The paper discusses the justifications for these recommendations, examines the strengths and weaknesses of the study, and concludes with ideas concerning the design and implementation of future similar studies.
Highcock, Nancy (New York University) [257]  
**Preliminary Investigations at Kınık Höyük, Southern Cappadocia: Hellenistic through Medieval Periods**

The site of Kınık Höyük, a sizeable tell settlement with monumental architecture and walls, presents an unparalleled archaeological opportunity to better understand the region of southern Cappadocia, Turkey, which served as a crossroads between the Near East and Europe. Excavations beginning in 2011 have uncovered information concerning the Middle and Late Iron Ages, Hellenistic, and Medieval periods of occupation within the citadel walls. This presentation will report on the architecture and diagnostic material of the later periods from the summit of the mound (operation B) before introducing new data retrieved during the 2013 season. This past summer, the team extended the investigation of the northern slopes (operation A) and began excavation in the lower town (Operation D) of the site. The excavation of the latter revealed a domestic context with levels of occupation dating to both the Hellenistic and Iron Age periods. Unlike the previous results from the tell itself, however, the lower town also produced ceramic material dating to the Roman and Byzantine periods, indicating different diachronic patterns of habitation for this area of the settlement. Furthermore, this burgeoning operation uncovered substantial evidence for household craft production, particularly of textiles, and the re-use of domestic architecture over time.

**Construction of Megalithic Pillar Sites in the Middle Holocene of NW Kenya: Social Change on an Economic Frontier**

The middle Holocene of NW Kenya saw many changes in economy, material culture, and social life: the advent of herding, production of Nderit pottery, and construction of “pillar sites” with standing stones, large rubble platforms, stone circles, and cairns. As the earliest public or “monumental” architecture in eastern Africa, pillar sites herald important developments in social organization. Three seasons of fieldwork west of Lake Turkana have dated construction and use of four pillar sites (GeJi9, GeJi10, GcJh3 and GcJh5) to 4300-3800 14C bp; three of these sites were in use within a few human generations of each other. The sites differ, however, in portable material culture and architectural layout. Excavations have revealed stone pavements, burial pits, curbs, and ashy areas within the deposits of some pillar sites. Mortuary activities are clearly represented within the platforms of three sites; individuals are typically buried with personal adornments such as beads made from stone or ostrich eggshell, but the nature, degree of elaboration, and physical location of personal ornamentation varies. Because several of the pillar sites saw practically contemporaneous use, differences among the sites suggests a complex social landscape in which multiple commemorative practices were employed, possibly by distinct cultural groups.

**The Montana Experiment: A Geoecological Model for Exploration and Discovery**

The Kokopelli Archaeological Research Fund (KARF) was created by an endowment from Joe and Ruth Cramer and ultimately supported both the Paleoindian Research Program (PRP) and the Ice-Age Research Program (IARP) at Montana State University. The endowment provided the opportunity for a two-pronged, collaborative approach to the study of late Pleistocene and early Holocene environments and human populations. The relatively-stable private funding source served as effective financial leverage that led to cooperative agreements with federal agencies and support from the National Science Foundation. A long-term research agenda that focused on the stratigraphic and chronologic framework for the northern Rockies and Great Plains was developed. The goal was to integrate lithostratigraphic, geomorphic, chronometric and paleontological data with known archaeological patterns to produce a geoarchaeological potential model for regional landscapes. Detailed field studies of known archaeological and paleontological localities were combined with stratigraphic and geomorphic studies from a wide variety of paleoenvironmental settings in non-glaciated and glaciated Montana landscapes. Initially based on an interest in the discovery and study of evidence for the presence of late Pleistocene humans, the
goals of KARF evolved to include developing a model that could be applied to understanding long-term ecological change.

[42] Houses of the Holy: A Ceremonial Cave Complex in the Northern Rio Grande
The site, Houses of the Holy (LA 102342), is a cave complex in Pilar, New Mexico that has served as a center for ritual behaviors over multiple millennia. The cave and its surrounding landscape were repeatedly visited by Archaic hunter-gatherers, Ancestral Pueblo groups, the Jicarilla Apache, and most recently by a community of new age practitioners from the town of Pilar. Although displaced in time, many of the panels display Archaic icons overlain by iconography from later periods. Multiple shrine features and ceramic pot drops found around the site indicate the Precolumbian use for Pueblo ritual. Campsites immediately outside the cave complex provide evidence of further usage by the Jicarilla Apache during the 18th and 19th centuries. The patterns of occupation and use of the landscape demonstrate a particular interest by these groups to visit and engage in ceremony at persistent places where meanings appear to have accrued and amplified over time. Here I report on recent research at the site and consider its implications for our understanding of the development of ritual practices situated within the wider landscape.

[71] The Defender
The title of this session highlights the prominent consideration of conceptual frameworks in both Professor Clark’s research and his teaching. My goal here is to extend one circle of his career by reexamining issues in the American Southwest, where he began in the field, in light of lessons he offers from the Old World Paleolithic. Themes of extinction, abandonment and collapse are common in archaeology and in the public imagination of archaeology. In a commonly implied notion of disappearance they often presuppose oversimplified categories such as species, cultures and civilizations. Moreover, inquiries into such disappearance often simplistically presuppose failure in a way that biases subsequent research. The categories of Neandertal and Hohokam, and their ostensible disappearance, illustrate in distinctive ways the common pitfalls of such presuppositions among professional archaeologists. Yet, these are also precisely the topics of greatest intrigue to a public audience even less prepared to appreciate the subtleties of our epistemology. As a well-known defender of students, Neandertals, and science, Professor Clark has inspired careful consideration of our concepts that we would all do well to emulate.

[175] Elemental Characterization of Floor Sediments from Housepit 54, Bridge River Housepit Village, British Columbia
Elemental characterization of sediments from living floors can aid in establishing past spatial organization and human behavioral adaptations. In this study, we utilize EDXRF and WDXRF techniques to examine floor sediments collected from BR2 and BR3 occupations of HP54 at the Bridge River housepit village. HP54 demonstrates a long history of occupation, containing as many as fifteen occupational floors interspersed with seven roof deposits. While the final floor post-dates contact, the underlying floors pre-date 1100 cal B.P. During excavation, HP54 was systematically sampled for sediments across multiple floors. A preliminary investigation was conducted in 2012 on sediment samples (N=40) associated with the historic Fur Trade occupation. Additional samples (N=93) were collected during the excavation of underlying floors associated with BR2 and BR3 occupations. We detail our methods for sample preparation to obtain reliable XRF data and implement geospatial tools to examine the results. Results suggest that elemental composition of sediments from floor contexts can be a valuable tool for discerning activity areas. This permits us to examine patterns of continuity and change in the organization of household space over multiple occupations.

Hill, Rebecca (Tulane University)
[195] Geochemical Characterization of Obsidian Artifacts from the Bolonchén District
This paper examines obsidian procurement strategies and production technology from the Preclassic through the Terminal Classic in the Bolonchén District of the Puuc Region of Yucatán, México. Obsidian artifacts from the archaeological sites of Huntichmul, Kiuic and Escalero al Cielo have been geochemically characterized with a Bruker Tracer III-SD handheld portable X-ray fluorescence spectrometer (pXRF). The obsidian artifacts included in this analysis were recovered during the investigations of the Bolonchén Regional Archaeological Project from 2000-2013. The results of the geochemical and technological analyses allow for a detailed examination of the spatial and temporal variability in obsidian procurement strategies and production technology in the Bolonchén District, contributing to our understanding of interregional and long-distance exchange.

Hill, Katie (Eastern New Mexico University)
[230] Adobe Walls: An Example of Depression Era Parkitecture
The Civilian Conservation Corps (CCC) was part of FDR’s New Deal campaign to kick-start the economy through public works. The CCC ran from 1933-1942 and constructed structures that fit with the parkitecture theme. Parkitecture is an approach for designing structures so that they blend in or compliment the environment. It is a practice of the National Park Service, the National Forest Service and other public lands agencies to construct buildings that are in harmony with the surroundings or express the regional culture history. Outside of Portales, New Mexico are the remains of a CCC camp and the nearly forgotten Eastern New Mexico State Park that its enrollees constructed. Two adobe structures, a bathhouse and a custodian’s dwelling, still stand on the site. These Depression Era parkitecture structures are less than a century old, but are rapidly deteriorating due to the elements. This camp has been recorded, mapped and photographed, with detailed drawings made of the two structures in order to preserve them on paper. Future research hopes to compare these with other structures of their kind built by the CCC in New Mexico.

Hill, David (Metropolitan State University of Denver) and Thomas Fenn (The University of Arizona)
[237] Lead Isotope Analysis of Glazed Ceramics from the Deh Luran Plain, Southwestern Iran
A major portion of Dr. Neely’s career has involved the publication of research that he conducted resulting from his participation in the survey and excavation of sites located on the Deh Luran Plain in southwestern Iran. The De Luran project represented one of the first archaeological projects to integrate methods derived from materials science to examine cultural material. In keeping with the tradition, the current study will address the variation in the potential sources of lead used as the flux in pottery glazes dating from the Parthian, Sassanian and Early Islamic Periods recovered during the survey of the Deh Luran Plain. This study will present analysis results for the lead isotope ratios from the ceramic glazes and compare them with newly available ore analysis data from the region.

Hills, Kendall
[130] Place-Making at Minanha: A Contextual Analysis of Epicentral Material Culture
The ancient Maya city-state of Minanha, located in west-central Belize, demonstrates a dynamic culture history, punctuated by the establishment of a royal court during the Late Classic period (A.D. 675-810). Over a period of eight years, intensive investigations performed within the Minanha Epicenter have produced a wealth of data and material culture. Informed through a contextual frequency distribution analysis of the epicentral special finds artifact assemblage, this paper provides a synthesis of the long-term occupation of the physical “space” that would, during the Late Classic period, emerge as the center’s seat of power. Emphasis is placed on understanding the diverse economic, political, social, and ritual practices that were carried out in this “place” from its initial occupation in the Late Preclassic period (400 B.C.-A.D. 100), to its final abandonment in the Early Postclassic period (A.D. 900-1200). Ultimately, the general trends that have emerged from this analysis inform us as to how this segment of the greater Minanha community changed over time. This paper demonstrates that Minanha’s Epicenter was a dynamic locus; with an ever evolving community.

Archaeological Settlement Patterns in the Province of Tlapa, Guerrero

In this work we present a spatial analysis of the distribution and chronology of archaeological remains in eastern Guerrero, Mexico, in the region referred to as Tlapa by the Spaniards. Synthesis of the results of field research as well as laboratory analysis undertaken by the Archaeology and Ethnohistory of La Montaña Project will be presented.

Hirth, Kenneth (Penn State University)

Early Olmec Obsidian Craft Production at San Lorenzo Tenochtitlan

The manufacture of obsidian prismatic blades has always been an important feature of Mesoamerican craft production. Recent archaeological explorations at the Olmec site of San Lorenzo Tenochtitlan have uncovered evidence for early obsidian craft production dating to the Early Formative period from 1200-1000 cal B.C. This paper presents the archaeological and technological evidence for this craft activity. These materials represent the earliest evidence for obsidian craft specialization currently known from Mesoamerica predating previously known blade workshop remains by 500 years. These data provide new perspectives on the origin of obsidian craft production, the spread of prismatic blade technology throughout Mesoamerica, and the procurement networks by which raw material suitable for manufacturing obsidian blades reached the Olmec Gulf Coast.

Hiscock, Peter [71] see Barton, C. Michael

State Formation Process in Japan from Economic Standpoint

Recent advances in Japanese archaeology have made clear spatial and temporal distribution of production sites of the Kofun Period. These results lead the author to a conclusion that the growth of large-scale production centers in the fifth century played an important role in the state formation in Japan. These production centers were of iron smith, pottery production, salt production, raising and producing horses, and bead production. Many of these production systems were introduced from the Korean peninsula. In the fourth century, local polities in northern Kyushu played dominant role in trade and interaction with the Korean peninsula. During the fifth century, however, the central polity of Kinai (present Nara and Osaka) gained direct control over trade and interaction with the Korean peninsula. At that time, numerous production centers came to be concentrated in the Kinai region. These phenomena were highly significant in the state formation. In the sixth century many local production centers grew. This was made possible because tribute economy to maintain the central polity developed. This became the foundation of taxation system in the following century when a state-level society matured.

Geomorphological and Topographic Indicators of Potential Neolithic Occupation in Northwest Jordan: Survey Results from Wadi Quseiba and Their Significance for Future Research

Two seasons of archaeological survey in Wadi Quseiba and its surrounding drainages in Northwest Jordan have revealed both artifactual evidence of Neolithic occupation, and geomorphological features suggestive of ideal locations for such occupation and its modern recovery. The survival and recovery of archaeological material is a consequence of erosion and sediment accumulation. This is especially true of surface collection by pedestrian survey. Based on this, targeted survey of Wadi Quseiba and its tributaries has been conducted, starting with a predictive model that accounts for the long-term transformative effects of erosion and sedimentation on the natural/cultural landscape. This has led the researchers to the conclusion that several remnant Neolithic terraces likely survive in the Wadi system. Previous research conducted in the area has revealed long-term correlative patterns between geomorphological features and sequences of occupation. With this, several areas have been flagged as having a high potential for being Neolithic occupation surfaces regardless of whether artifactual evidence was located during surface survey. These geomorphological indicators will serve as criteria for future research in the form of excavation to confirm Neolithic occupation, bolster the record of such occupation in the region, and allow for new discussion of Neolithic landuse in the region.

ABSTRACTS OF THE SAA 79TH ANNUAL MEETING

Hlubik, Sarah (Rutgers University), Emily Wahler (Rutgers, The State University of New Jersey), Craig Feibel (Rutgers, The State University of New Jersey) and John WK Harris (Rutgers, The State University of New Jersey)

Survey and prospection can be both a rewarding and time-consuming activity in the life of the archaeologist. There is a constant need to identify effective prospection methods using remote sensing technology. Satellite imagery, using multi- or hyper-spectral technology may be able to increase efficiency of survey and improve discovery rates of potential sites. The spectra of sediments will differ according to mineralogical make-up; this can be used on a large scale to help discover sites, and on a small-scale to identify intrasite changes that could indicate the location of features. Given the high cost of high-quality satellite images, it is not always possible to obtain the most recent, highest-resolution imagery available. However, recent advances in digital camera technology may make it possible to mimic the functionality of multi-and possibly hyper-spectral imagery by modifying high-resolution digital cameras to take infrared and ultraviolet photos. These cameras can be used with visible spectrum cameras to take photos of survey areas and sites with low-altitude aerial photography. This project proposes a methodology and evaluates its effectiveness to identify different sediments on a large scale as well as the ability to identify intrasite differences that may indicate feature presence.

[148] A 13,000 Year Record of Subsistence Change at Bonneville Estates Rockshelter

Bonneville Estates Rockshelter (BER), eastern Nevada, was initially occupied by humans about 13,100 years ago. Intermittent occupations continued until very recently. All prehistoric phases recognized from the north-central Great Basin are present, and all contain an abundance of well-preserved faunal remains. Previous publications have identified two general trends in the early BER fauna exploited by human foragers: (1) high diversity in the Late Pleistocene-Early Holocene occupations, centered on the capture on large and small terrestrial mammals, birds (sage grouse), and insects (katydids) during a cool and moist climate; and (2) a focus on artiodactyls during the warm and dry Middle Holocene. I update these early records with a complete listing of the fauna recovered from the shelter, corroborating these trends. I present for the first time changes in human diet based on the faunal record throughout the Late Holocene at BER (ca. post-5,100 years ago). I then correlate trends in faunal use with nine climatic phases recognized in the Great Basin over the past 13,000 years, showing connections and disconnections between the two. I end the paper with suggestions on future directions archaeologists may wish to consider when interpreting human dietary decision-making in Great Basin foragers.

[326] From the Ground Up: Building a Community-Based Archaeology of Banks Island, Arctic Canada

Here, we discuss our attempts to overcome some of the challenges of developing a community-based archaeological research project in the small, remote Arctic community of Sachs Harbour, Northwest Territories. These challenges include research fatigue, local politics and logistical difficulties, which are doubtless faced by other archaeologists collaborating with local communities, whether the collaboration is initiated by the archaeologists (as in this case) or the community. We outline the specifics of these challenges in Sachs Harbour and illustrate how we are using non-invasive techniques including archaeological geophysics, 3D modeling and ethnography in concert with social media in an attempt to
build trust, encourage community participation, and facilitate dialogue.

[42] Resource Depression within the Ancestral Pueblo Goodman Point Community

Prior to the depopulation of the San Juan (Four Corners) region (circa A.D. 1300), Ancestral Puebloan people faced challenges of declining and changing faunal resources due to their increasing population density in the context of climatic shifts. Several recently excavated archaeological sites within the Goodman Point Pueblo Unit in southwestern Colorado, spanning a long temporal occupation (circa A.D. 1000-1280), contain thousands of animal remains. We explore local spatiotemporal variability in faunal resources within the Goodman Point community by examining taxonomic abundance and prey choice. These analyses facilitate an investigation into the differences in the exploitation of domesticated and wild animal resources. Our results indicate a decreasing reliance on domesticated resources and increasing diet breadth at the end of the occupation, mirroring results found within the larger San Juan region.

[24] In Pursuit of the First People on the Central Plains

During the past decade research in the Central Plains region supported by the Odyssey Archaeological Research Fund has targeted localities with the earliest known evidence and potential evidence for human occupation. Investigations include those at Kanorado, Burntwood Creek, Claussen, Vincent-Donovan, Brookings, SimmsHauser, Schuerman, Big Eddy, Coffey, and others. This paper reviews key evidence and findings from some of these sites, documents the scope of Odyssey-supported research and how the search for early sites has developed and been refined during the decade. The unequivocal documentation of pre-13,000 year old human occupation in the region through Odyssey research has not occurred, but arguments for why we believe such evidence exists are presented.

[316] Ancient DNA and the Origin of the Catalina Island Ground Squirrel

The Catalina Island ground squirrel is a form of the California ground squirrel (Otospermophilus beecheyi) found in mainland California and may be a fairly recent introduction to the island of Catalina. The differences between mainland and island O. beecheyi are limited, including a slightly larger skull and hind feet and an apparently darker color. Relatively few studies have investigated the ecology and natural history of Catalina Island ground squirrels and no studies of island ground squirrel genetics have been performed. The island squirrels appear to fill the same niche as mainland ground squirrels, but they occur in several archaeological sites and some bones which are burned or have possible cutmarks suggest they were hunted and/or scavenged by Native Americans. Here we report recent genetic analysis of ancient and modern ground squirrels and radiocarbon dates on archaeological ground squirrel bones. These data help evaluate the dispersal and evolutionary history of Catalina Island squirrels, as well as the relationship of such developments to changing human occupations (e.g., Native American, historical ranching, and modern).

Hogan, Patrick [87] see Worman, F. Scott

Hogan, Maura (Indiana University)

Grit tempering is a diagnostic feature of Late Woodland pottery, and is often used to distinguish earlier
occupations at multi-component sites within the American Bottom region and across the Southeastern U.S. Techno-functional analyses highlight how the inclusion of specific tempering agents will affect the performance characteristics of a vessel, and by extension, temper choice is most often interpreted with respect to these performance characteristics. In analyses of Late Woodland, grit-tempered ceramic assemblages, less attention has been paid to the non-technical considerations that guide temper choice. An alternative is to examine the social context of temper selection. Studies of materiality propose that the phenomenological properties and point of origin of substances are endowed with social and cosmological significance. This poster presents data collected on a sample of Late Woodland pottery from an upland, multi-component in Lebanon, IL, and considers the potential for tempering choice to provide insight into the social landscape. Preliminary results of this analysis suggests that, in some cases, the exclusive use of a single mineral or material for tempering and the placement of discarded sherds appear to be purposeful choices, informed by historical connections to places on the physical landscape and by social ties with neighboring communities.

Högberg, Anders (Linnaeus University)

[115] Children and the Materiality of Social Learning within the Evolution of Mankind and Behavioral Modernity

Recent research has re-written the history of evolution of modern humans. Studies have shown that early modern humans evolved in sub-Saharan Africa c. 200,000 years ago, that modern humans and Neanderthals existed simultaneous for more than 10,000 years in Europe, that behavioral modernity is to be seen as developed by environmental and social processes among both archaic and modern humans, and that modern and archaic humans interbred. But, few studies have been conducted that in an interdisciplinary and global manner focus on the essence of that which develops and maintains behavioral modernity, i.e. cultural and social learning and intergenerational transmission of knowledge. More research is needed on how social learning came about, which artifacts and technologies were handled, how knowledge of these was preserved, transmitted and further developed in the form of innovations from one generation to another and which evolutionary consequences this has had. In this paper I will discuss how an understanding of the role played by the children and materiality of social learning can contribute to interpretations on evolution of mankind and behavioral modernity.

[76] What Does Collaborative Archaeology Mean to You?

Archaeologists are becoming increasingly aware that archaeology affects living people, including descendant communities on whose lands they work. In British Columbia, Canada, First Nations are asserting treaty rights and titles, including their rights to proper consultation and accommodation before projects occur in their territories. These assertions, and consequent court decisions and government policy alterations, are obliging archaeologists to determine how to collaborate with descendant communities. However, as there is no mandated legal framework for collaborative practices, archaeologists and other stakeholders are creating informal and experimental policies and practices. Because these informal means of collaboration may become the next generation of law and policy, they deserve research attention to identify the most just and effective forms of engagement. Our project does just that, by using measureable attributes of collaborative practices to analyze information from British Columbia archaeology projects, including consulting, field schools, and research projects. Our assessment provides answers to how, to what extent, and to what ends archaeologists and descendant communities are working together, and highlights the diversity of community-engagement in British Columbia.

[21] Postclassic Settlement and Population Movement at Baking Pot and in the Belize River Valley

While most centers in the upper Belize River valley were abandoned during the Late and Terminal Classic, people continued to reside at Baking Pot for hundreds of years. However, Postclassic occupation was characterized by changes in the settlement pattern, along with distinct shifts in the material culture of households in the eastern settlement of the site. Burial patterns that endured for generations also changed significantly, suggesting broad changes in ritual practices. In this paper, we explore the origins of Baking Pot residents during the Postclassic period using biogeochemical and archaeological data. Strontium, oxygen, and carbon isotope values for three Postclassic burials provide a
comparison with Late and Terminal Classic migration patterns of 29 individuals buried in household and public contexts. Osteological analyses that include dental metric and non-metric epigenetic traits and a taphonomic analysis of funerary treatment provide insight into the changes that occurred during and after the sociopolitical collapse at Baking Pot and elsewhere in the Maya lowlands.

[148] Early Holocene Mobility and Technological Activities at Connley Caves 5 and 6 (35LK50), in South-Central Oregon

The Connley Caves consist of eight wave-cut rockshelters and caves located on the west side of the Connley Hills in the Fort Rock Basin in south-central Oregon. Here, we provide a first look at the lithic assemblage from Cave’s 5 and 6 and discuss the possibility of occupations during the earlier Paisley Period (16,000 - 12,900 cal. yr B.P.). Previous research in the late 1960s revealed deep, well-stratified cultural deposits potentially dating to this period. The site was reopened during the summers of 2000 and 2001 as part of a larger study of early forager lifeways throughout the Fort Rock Basin by the University of Oregon field school. Two cultural components, the upper and lower pre-Mazama (the Lunette Lake and Fort Rock periods, respectively), were identified during these excavations. The Lunette Lake component was directly dated to between 9000 and 8500 cal. yr B.P. and the Fort Rock component was directly dated between 11,000 and 9800 cal. yr B.P. We discuss the technological organization, toolstone provisioning, and settlement patterns of the Western Stemmed peoples that occupied the site during the early Holocene and place the site in a broader regional context.

[42] Preliminary Results of Survey and Excavations at a Late Bonito Great House in Chaco Canyon, New Mexico

Summer 2013 saw initial investigations at Roberts’ Great House, a Late Bonito subphase (1100-1140 CE) great house in Chaco Canyon, New Mexico. Initially explored by Frank H. H. Roberts in 1926, the site is threatened by severe erosion. Sections of the site have already collapsed into the main arroyo and proximal tributary bounding the site. Following extensive surface mapping, excavations were limited in scope and designed to assess erosional damage, occupation history, and inform a more precise map of the site. Initial results indicate that Roberts’ map, upon which subsequent researchers have relied, underestimated the size of the great house. Additionally, the scale of earlier Basketmaker III and Pueblo I occupations are more substantial than previously indicated. Artifacts and architecture reflect a long, complex, and episodic occupational history spanning 700 years. In this poster, we present preliminary findings of our excavation and mapping efforts, highlighting the potential for the application of leading edge 3D technologies in the assessment of threatened cultural resources.

Holliday, Vance (University of Arizona), Bruce Huckell (University of New Mexico) and Jesse Ballenger (Statistical Research Incorporated)

The Argonaut Archaeological Research Fund (AARF) was established at the University of Arizona by Joe and Ruth Cramer in 2001. AARF’s mission focuses on the archaeology and geochronology of First Americans in the American Southwest, including northwest Mexico. In central New Mexico AARF
supported excavation and stratigraphic mapping of the Boca Negra Wash and Deann’s Folsom sites in the Albuquerque Basin, and a long-term program of testing, mapping and coring of the extensive Mockingbird Gap Clovis site on the Jornada del Muerto. This research suggests that Clovis and Folsom subsistence in this region was focused on bison hunting carried out by small, mobile groups adjacent to playa wetlands and marshy draw environments. AARF work in the San Pedro Valley of Arizona has pushed the alluvial chronology of the inner valley back to Clovis times, mapped the distribution of “black mats,” and continued testing of mammoth sites in the valley. Inventories of surface finds map the occurrence of Paleoindian occupations throughout the AARF region. High concentrations of Folsom sites are documented along the Rio Grande Valley, but no Folsom artifacts are known from southern Arizona or northwest Mexico.

Holly, Donald (Eastern Illinois University) and Paul Prince (MacEwan University) [325] Separate and Unequal: Amerindian and Paleoeskimo Settlement and Subsistence Patterns on the Island of Newfoundland

For nearly a thousand years, Amerindians and Paleoeskimos shared the island of Newfoundland. During this time, Paleoeskimo peoples practiced a rather specialized maritime-focused settlement and subsistence strategy. In contrast, Amerindians pursued a more mobile and generalized approach that made greater use of interior resources. The reasons for these differences may be partly cultural, but it is suggested that they also reflect the relative power of Paleoeskimo peoples at the time. Through an examination of settlement patterns and an analysis of faunal remains from the interior of the island, we propose that the formidable presence of Paleoeskimo peoples on the coast effectively marginalized Amerindian peoples to the extent that their subsistence economy was jeopardized.

Holt Mehta, Haley (Tulane University) [275] Investigating Settlement and Identity at El Tesoro, a Classic Period Zapotec Settlement in the Tula Area

The Tula area is well known for its fluorescence in the Early Postclassic period and its significance to the Aztecs later in time. This region also was of great importance to the state of Teotihuacan in the Early Classic period, when it was colonized for agricultural land and lime extraction. Complicating the social landscape further, archaeological evidence indicates Zapotec people were part of this Teotihuacan incursion in the Tula area. Abundant Zapotec-style pottery and at least two Zapotec-style tombs have been recovered from three sites in the area, including at the Teotihuacan administrative center of Chingu. This paper presents ongoing research from one of these sites, El Tesoro, located 20 kilometers south of what would become the great Toltec capital. Recent investigations there show evidence for an apparent hybridized Zapotec-Teotihuacano settlement, which may indicate a strong relationship with the Oaxaca Barrio of Teotihuacan and its inhabitants.

Homburg, Jeffrey (SRI/University of Arizona), Michael Heilen (Statistical Research, Inc.) and Phillip Leckman (Statistical Research, Inc.) [294] Modeling Ancient Agricultural Land Use in the Southern Chuska Valley, New Mexico

The US 491 project provided an opportunity to model agricultural systems that supported settlements concentrated in the Chuska Valley in northwest New Mexico. We analyzed GIS data, soil data, and ethnographic information to model agricultural field locations, soil quality, and anthropogenic effects of cultivation on soil productivity. Soil survey-, topographic-, and hydrological-data were analyzed for known agricultural runoff fields to identify the salient characteristics of these fields and to model other potential field locations across the study area. Analysis considered factors such as slope elements, gradients, and watershed sizes, along with soil quality variables, such as available water content, pH, texture, and horizon depth. Long-term properties of soil quality were measured for suspected fields along the US 491 corridor using chemical and physical tests (organic and inorganic carbon, nitrogen, available and total phosphorus, pH, bulk density, and particle-size analysis) to assess the nutrient status, compaction effects, and soil-water characteristics of agricultural fields. Together, these analyses allowed us to evaluate agricultural potential and cultivation effects for different parts of the study area and to assess changing relationships through time of aboriginal settlements to potential field locations.

*Boodie Cave Archaeology in Its Biogeographical Context*

One of the principal aims of the Barrow Island Archaeology Project is the investigation of coastal societies of northwest Australia and resultant behavioral responses to changing sea levels, coastal productivity and then isolation. Boodie Cave lies on the boundary between two biogeographic regions, and despite climatic changes through time, comparisons between the existing biogeographical regions where a large body of surface archaeological corpus can be investigated. Further, the incorporation of data from the current mainland coastline dated to the late Holocene will provide additional insights into Aboriginal cultural responses and a counterpoint to the changes observed on Barrow Island during the early Holocene/late Pleistocene.

Hoppa, Kristin (University of California, Santa Barbara) [170]  
*Weaving Together the Macro and the Micro: Archaeobotanical Evidence from Middle Holocene Sites on Santa Cruz Island, California*

This study considers two lines of archaeobotanical evidence from four Middle Holocene sites on Santa Cruz Island, California: seeds recovered through soil flotation and starch grains recovered from the surface of groundstone artifacts. The low density of seeds recovered during initial macrobotanical analysis indicated scarce evidence for plant exploitation; however, starch grains recovered from the surface of groundstone artifacts provide direct evidence of plant processing. Indeed, these two lines of evidence tell very different stories about hunter-gatherer plant use. In order to contextualize these findings, this paper will discuss results of experimental processing and recovery of both seeds and starch grains from the comparative collection at the University of California, Santa Barbara. This paper explores preservation and recovery issues related to seeds and starch grains in terms of taphonomic challenges and laboratory methods, and suggests ways to weave together these multiple lines of evidence to gain broader understandings of prehistoric subsistence strategies.

*Rocking the Major Networks in Prime Time: Resource Mobilization and Socioeconomic Interaction in the Middle Preclassic Belize Valley*

Investigations in the Belize Valley reveal the Middle Preclassic (900–300 B.C.) landscape as the setting of dynamic interactions that shaped complex societies in succeeding periods. Evidence suggests that individuals, households, and communities participated in multifaceted, intertwining webs of socioeconomic networks that mobilized resources necessary for both basic subsistence and more esoteric pursuits. Participation in networks involving repeated, interpersonal interaction is an important factor in the creation of social personae within communities, and may have played a direct role in the development of social complexity in the Belize Valley and elsewhere in the Maya Lowlands. This poster presents a spatial analysis of artifact consumption patterns from Middle Preclassic contexts at the site of Cahal Pech, Belize. It compares the intra-site distributions of artifacts made from raw materials deriving from geographically circumscribed source areas in the broader Maya region. Delineation of patterning in the relative frequencies and geographic origins of artifacts deposited at different architectural features is used to reconstruct the spatial character and extent of the networks that linked different webs of producers and consumers. This study demonstrates that differential participation in socioeconomic networks acted as a catalyst for emerging social complexity and differentiation during the Middle Preclassic.

*Morphometric Analysis of Shape Variability Among Flaked Stemmed Obsidian Tools from Easter*
Island
It is often assumed that prehistoric Easter Island populations experienced intense warfare, particularly during late prehistory. One line of evidence that is used to make this assumption is the presence of mata’a, or flaked stemmed obsidian tools that are found on the surface by the thousands. Previous stylistic analyses and evaluation of use ware contradict claims of weapons and instead point to their use as either some kind of symbolic implement or as a part of cultivation activities. Here, we use shape morphometric analyses to examine mata’a variability and look for areas of shape that are constrained versus those that are free to vary. Our results suggest that mata’a were only functionally constrained in terms of the haft. These results continue to support the alternative hypothesis that these artifacts were not used as weapons.

Horowitz, Rachel (Tulane University)
[302] Technological and Economic Implications of Chert Extraction and Production at Callar Creek Quarry, Belize
Chert resources are fairly ubiquitous in much of Mesoamerica. Likewise, chert tools are found in many contexts, emphasizing their importance both technologically and economically. This paper examines the extraction and production of chert resources at a chert source, Callar Creek Quarry, in western Belize. Excavations at the quarry and surrounding households examined the extraction and production processes, through a technological organization approach, and how access to these materials was organized. Investigations demonstrate that Callar Creek Quarry, and surrounding household groups, were linked to regional political and economic dynamics. This paper will discuss the processes of extraction and production of chert at Callar Creek Quarry, the organization of these activities, and how these activities served to integrate this hinterland area into the broader regional political and economic sphere.

[302] Chair

Horrell, Christopher and Amy Borgens
The Monterey Shipwrecks are just a few of the many significant deep-water sites discovered in recent years due to offshore oil and gas exploration. Monterey Shipwreck A is only the second deep-water archaeological excavation conducted in the Gulf of Mexico. As a complete excavation of the site was not feasible, research questions and objectives were developed to formulate a recovery plan for the data and to collect diagnostic photography and video of items remaining on the seafloor. These questions and objectives were drafted within a larger theoretical and methodical framework providing context for the eventual findings. Due to a depth of 4,300 ft., a remotely operated vehicle (ROV) was utilized with purpose-built tools and equipment to recover archaeological and environmental samples. The ROV-artifact recovery effort was broadcast live from E/V Nautilus using telepresence enabling archaeologists to describe ongoing work, share initial site observations, and respond to public inquires.

Horrell, Christopher [307] see Hanselmann, Frederick

Horsley, Timothy (Horsley Archaeological Prospection, LLC), Casey Barrier (Museum of Anthropology, University of Michigan) and Alice Wright (Museum of Anthropology, University of Michigan)
Geophysical surveys have the potential to significantly contribute to archaeological research projects when effectively integrated with more traditional methods. In this paper, we identify three key components to maximize this potential: (i) begin with an extensive geophysical survey to establish the function, organization, and archaeological potential of a site; (ii) maintain collaboration between geophysical archaeologists and traditional archaeologists throughout the investigation; and (iii) adopt a flexible research design. Incorporating all three has allowed us to both prospect for new and appropriate research questions, and devise suitable strategies to address them. It has also encouraged continual feedback between the geophysical and archaeological data to improve interpretations and develop new hypotheses. This interdisciplinary methodology is demonstrated through two case studies from mound sites in the Southeast United States: the Late Woodland-Early Mississippian Washausen site in Illinois; and the Middle Woodland Garden Creek site in North Carolina.
Horton, Elizabeth (Arkansas Archaeological Survey)

[22]  *Weaving from Forests: Fiber Use and Fabric Production in the Ozark Plateau, Southeastern United States*

The dry caves and rockshelters of the Ozark Plateau in the Southeastern United States have yielded a remarkably well-preserved record of fiber use and fabric production by pre-Columbian peoples stretching back at least 3,000 years. Intensive ongoing studies of technological and stylistic choices in fabric production and fiber use raise important questions about continuity and change in these perishables technologies from hunter-gather to agricultural societies. Here I explore several case-studies in fiber use that link transitions in social organization and shifts in food pathways with conservation and innovation in the use, processing, and possibly management of fiber plant resources in the Ozark Plateau from the Late Archaic to the Late Prehistoric periods.

Horton, Elizabeth (National Park Service, Washington State University)

[176]  *Resistance through Subsistence: Modoc Resource Strategies During the 1873 Modoc War*

Nineteenth century Euro-American settlement of Northern California brought about significant social changes in the lifeways of the Modoc People, particularly during the 1873 Modoc War with the U.S. Army. For the majority of the war, the Modoc held their traditional defensive position in the lava beds on the south shore of Tule Lake, now known as Captain Jack’s Stronghold, currently in Lava Beds National Monument in northern California. During the four month siege, the Modoc acquired a small herd of cattle for consumption, and disposed the bone refuse into crevices within the stronghold. Zooarchaeological analyses of several campsites, including those occupied by Shacknasty Jim and the Hot Creek band, provided insight into the social processes at work amongst a people under siege, particularly the influence of oral traditions and risk management strategies on community consumption practices.

Houk, Brett (Texas Tech University)

[37]  *Patterns of Force: Deciphering the Geopolitical Landscape of the Eastern Maya Lowlands*

Reconstructing the geopolitical landscape of the eastern Maya lowlands is a difficult task. Not only are there few kingdoms with hieroglyphic inscriptions, but we also have little understanding of the geographic extent of political authority at most sites. Actual borders between kingdoms—or boundaries between competing groups of diplomatically aligned kingdoms—probably did not exist except as fluid zones of contested political and economic influence. While the search for boundaries may prove to be a frustrating on-the-ground exercise, studying the urban designs of cities on a regional scale may lead to the identification of clusters of affiliated kingdoms and, by extension, buffer zones between them. One weapon in the analytical arsenal of site planning studies is to look for evidence of political emulation, which may suggest affiliation. However, this paper proposes that identifying the rare architectural elements, or rare arrangement of elements, that co-occur at nearby sites may provide the best evidence for emulation and/or affiliation. Case studies from northern Belize and northeastern Petén offer an example of this approach. This paper also includes some speculation about how Maya architects acquired and transmitted planning ideas, and cautions that extending a political emulation model over great distances is inherently problematic.

[90]  *Rock Art as Solar Markers: Defining Cultural Intent*

Interpretation of rock art is one of the great challenges of cognitive archaeology. The most objective interpretations and evidence of intentionality of rock art are preserved in solar markers. We start by defining rock art solar markers and then we will discuss the use of astronomical analysis on rock art to
show how the solar interactions preserve the astronomical knowledge and define the cultural intent. We believe this astronomical evidence supports the intentionality of the culture and individual responsible for inscribing the rock art. We will discuss the concepts of anticipatory, confirmation, and resolving power in relation to rock art and how these in turn are established through horizon astronomy methods. We offer as tool or guide a matrix of intentionality to score rock art panels, which can be used in two ways. First, to grade known solar markers as to cultural intent and secondly, to help identify new potential solar markers. We will demonstrate the matrix concepts based on our investigation of the pictographs at Paint Rock, Texas.

Houston, Stephen (Brown University) [162] Chair

Howard, Joshua (SUNY University at Buffalo) and Caroline Funk (SUNY University at Buffalo) [173] Bone Tools of the Rat Islands
A study of the Rat Islands was conducted in 2003 and 2009 to examine the Aleut sites found in the area to better understand the subsistence strategies, use of the environment, and the importance of landscape and seascape to the Aleut culture. During this study, due to the excellent preservation of bone at the RAT-081 site, over six thousand faunal remains were recovered including a number of bone tools. The bone tools recovered date from 1000 to 300 years ago and are made up of fish, sea mammals, and bird species. The recovery of bone tools allows for a unique examination of the everyday lives of the coastal Aleut through perishable artifacts that are under most conditions lost in the archaeological record. The poster will discuss the current state of research being undertaken on the Rat Island bone tools in order to better understand Aleut history, use of bone tools, bone tool technology, and subsistence strategies.

Howard, Margaret (Texas Parks & Wildlife) [199] Prehistoric Settlement on Devils River State Natural Area, Lower Pecos Texas
The remarkable stability in technology, material culture, and diet during the 8,000 year Lower Pecos Archaic may mask changes in the cultural landscape over time and space. Two settlement models have been proposed based on distribution of water and plant resources: concentration of populations along rivers with logistical use of the uplands, and foraging by mobile bands. The preponderance of investigations in large sites along the deeply entrenched Rio Grande and lower Pecos River has skewed interpretation toward the sedentary model. Data from the south unit of Devils River State Natural Area are used to test these models on the perennial lower reach of this river, where the terrain is not as steep. A geodatabase from four years of survey covering ca. 8,000 acres, 300 dated projectile points, and rock art distributions are used to shed light on Lower Pecos Archaic population densities, settlement choices, subsistence strategies, and cultural landscapes.

Howe, Jessica and Jodi Barnes (Arkansas Archaeological Survey) [76] Pots and Pipes from the Austin Site: Public Archaeology in Southeast Arkansas
The Austin Site (3DR50) is located in Drew County, Arkansas along Bayou Bartholomew. The site, a late prehistoric Native American cemetery, was heavily looted for pots and no longer exists due to land leveling. Much of what we know about the site comes from one of its pothunters, Curly Birch, as well as scientific excavations performed by Birch and members of the Arkansas Archaeological Society in 1972. Birch donated his collection of pots and pipes to the Arkansas Archaeological Survey. The collection tells a story about the problem of looting, the importance of the Arkansas Archaeological Society, and the archaeology of southeastern Arkansas.

Howe, Mark (US State Department - USIBWC) [87] The United States International Boundary and Water Commission: Geoarchaeological Explorations along the US / Mexican Border from the Pacific to the Gulf Of Mexico
The USIBWC was established in 1848 after the Mexican-American War. The primary duties are to oversee issues along the International Boundary in land, water and treaty issues. As the border infrastructure has aged, attention to archaeology has been more focused for Cultural Resource Management. Over half of the boundary is the Rio Grande River in Texas with the rest consisting of the Colorado River and land, west to the Pacific Ocean from El Paso, Texas. Our projects in the past year
have primarily focused on resource management but also on geoarchaeological investigations. This presentation will address a history of some of the projects we have been working on. These have been geoarchaeological testing at and data recovery from Fort Brown, TX, (1846–1945), Fort Bliss, TX, (1879–1893) and Amistad and Falcon Reservoirs on the Rio Grande. Our final analysis is how sites are affected by the rivers along the border and the mitigation and research measures we are completing. This presentation will show that the USIBWC is focusing on Cultural Resource Management in both water and land use planning along the US / Mexican border with an emphasis on the rich history of the Borderlands.

Howell, Angelina
[331] Unknown Quantities: Critical Impacts of Science in Society
The principle questions raised in this presentation explore the short and long term impacts of archaeological research on the economic, social and political landscapes of the rural communities in which it is often conducted. Specific data and analysis will illustrate the empiric paths of the economic impacts of archaeological research projects and how these impacts are reflected back out into the economic, social and political systems of local communities. Finally, the presentation outlines basic models for identifying aspects of research that may help define a 'footprint' of activities related to scientific research.

[122] Instrument Morphology and Cultural Preferences
Information on aural preferences for pre-Contact Native American cultures can be partly gained through morphological examinations of archaeologically recovered soundmakers. For instance, unique to some Mesoamerican edgetone instruments, like flutes and whistles, is a ridge placed around the aperture (sometimes called the window), which dramatically affects tone quality, or timbre, by influencing the volume level of sound waves through the control of directionality and force of airflow at the point where the wave is split. The higher the ridge the fewer audible overtones are incorporated into the sound of the fundamental tone, the instrument's lowest pitch. There are many Mesoamerican instrument types that include components affecting sound quality, such that this speaker and others (O'Brien-Rothe, Rodriguez, Boiles, Franco) theorize that acoustic sophistication demonstrated in pre-Contact instrument design was largely aimed at producing sundry timbral effects. If true, there are implications in such a non-Western music affinity, which would be helpful in archaeological interpretations. In my discussion, I will examine ancient Mesoamerican soundmakers to determine what their morphology can tell us about cultural aural preferences in holistic terms, while assessing modern Western ones to determine what their morphology tells us about our own tastes, in music and beyond.

Howey, Meghan (University of New Hampshire)
[338] Sympathetic Magic in Indigenous Consumer Choice during Early Contact in the Northeast and Great Lakes
Research increasingly shows that from earliest contact with Europeans, indigenous peoples of eastern North America acted not as wholesale receivers of European goods, but as discriminating consumers of these objects. While indigenous people found themselves increasingly involved in a market economy, value was not solely directed by Europeans; it was frequently ascribed to European objects within indigenous frames of reference. Sympathetic magic was one such frame of reference that drove the economic valuation of European goods during early contact. Rather than interpreting magic as a naïve impulse of “primitive” peoples as many early anthropologists did, I argue the use of sympathetic magic in the valuation and consumption of European goods by indigenous peoples was sophisticated, meaningful, and functional. Two vignettes about one particularly popular European good, the kettle, are offered to show indigenous communities deployed both types of sympathetic magic, imitative and contagious, in their consumption of kettles. Through both imitation and contagion, indigenous peoples across the Northeast and Great Lakes used sympathetic magic to direct the consumption of European goods and to make these goods ones that registered and publicized the strength of their desire to exert control over the changing world they found themselves in after contact.

[123] Sitting on the Dock of the Bay: Ceramic Connections between Lamanai and the Chetumal Bay
Area over More Than Two Millennia

The advantageous geographic location of city centers situated in coastal areas and on river systems in northern Belize enabled participation in regional networks of exchange linked to large consumer markets in both the Southern and Northern Lowlands. At sites such as Lamanai, the presence of material goods deriving from geographically distant raw material sources provides evidence of connections to multiple and far-flung localities within the greater Lowland region. The movement of material commodities over these long distances, from their geographic origin to where they were ultimately deposited, over land and by watercraft, must have involved stops at multiple intermediary locations. These stops en-route would have provided additional opportunities to acquire and exchange material goods. These short-distance transactions have received less attention, although they are equally critical to our understanding of trade routes and travel. This paper examines the material evidence of short-distance exchange between the Chetumal Bay area and Lamanai, situated on a river system connecting coastal to inland areas to the south. Our focus is the petrographic evidence of pottery originating from the Bay area at Lamanai, examining patterns in its frequency and variability from Late Preclassic to Spanish Colonial times and identifying changes in patterns of consumption.

[65] Archaeological Survey and GIS-based Investigation into Site Formation Processes through Balloon Photography and Structure from Motion

The innovative combination of both new and tried-and-true methods can revolutionize the process of documenting, analyzing, and visualizing spatial archaeological data. New approaches can pay special benefits when surveying and planning excavation at archaeological sites that are relatively poorly-documented. Low-altitude aerial photography combined with photogrammetric Structure from Motion make up a workflow that allows for precise and accurate recording of both photographic and elevation data of archaeological sites with a great deal of speed and efficiency. Through these techniques, the researcher can create spatially-referenced orthophotos and digital elevation models (DEMs), which, among other things, can serve as the basis for investigations into site formation processes. Due to the newly-possible rapidity of creation of these datasets, analyses of certain cultural and natural formation processes can be completed over the course of hours or days and further archaeological investigation can be undertaken based on the results. This paper presents a case study of the application of these methods at two sites Wadi Fidan 61, a Neolithic site, and Khirbet Nuqayb al-Asaymir, an Islamic period site, both located in Southern Jordan and investigated as part of UC San Diego’s Edom Lowlands Regional Archaeology Project.

[315] Pennsylvania’s Shift from the Pleistocene to the Holocene: Using GIS Models to examine Cultural Continuity between Paleoindian an Early Archaic Peoples

Recent trends in research have described the first human beings to enter North America not as exclusively big game hunters, but as general foragers that used a plethora of natural resources. Accompanying this research has been the notion of regional variation amongst groups of the earliest North American people. Variation geographically in turn allows archaeologist to study trends of cultural continuity. The aim of this study is to evaluate the possibilities of such continuity between the people living in Pennsylvania in the late Pleistocene and those who lived in the same region in the early Holocene epoch. Pennsylvania utilizes a GIS (PA CRGIS) system to catalogue its cultural resources. Included in this database are locations of many known Paleoindian and Early Archaic sites. Previous work by Dr. Kurt Carr has examined the distribution of many of these earliest sites. Programs such as ARC GIS allow for further investigation into the landscape use patterns of the earliest human beings living in the late Pleistocene and early Holocene periods, and can add greater understanding of how these sites are related within the landscape. Beyond site distribution new variables will be tested to evaluate the cultural relation of Pennsylvania’s earliest inhabitants.

Hranicky, William

[133] The Arkfeld Site: An Early Paleoindian Quarry in Frederick County, Virginia
This paper presents a sample of artifacts and an overview of the Arkfeld paleosite in Virginia which offers an insight to the before and during the Clovis time periods in Virginia and the eastern U.S. The site consists mainly of shale and rhyolite quarry produced implements. The basic lithic method at the site is a blade technology with few bifaces. The site has no classic projectile points and contains artifacts which have not been reported in the literature. The site is classified as before Clovis and has produced numerous bipoints.

**[124] Shifting Land Use: The Role and Impact of Ecological Diversity in Ancient Mesopotamian Landscapes**

At the onset of the 4th millennium B.C., Sumerian civilization in southern Iraq exhibited a level of economic differentiation, socio-political complexity, and urbanization previously unseen anywhere in the ancient world. The processes that began at that time culminated a millennium later in the formation of a powerful, persistent city-state system across southern Mesopotamia in the 3rd millennium B.C. Past anthropological models attempting to explain the emergence of urban societies in this area have relied on a combination of data derived from circumscribed surface survey and later historical records, and emphasized the expansive and complex irrigated agricultural system and activities related to pastoralism as underpinning the broader social, political and economic developments. Recent changes in access to the Iraqi landscape allowing new fieldwork, the emergence of relatively new spatial analysis tools such as GIS, and increasingly high resolution, but low-cost remote sensing datasets enable the exploration of marsh environments and ecological diversity as a complementary and importance component of the Mesopotamian socioeconomic landscape.

**[267] An Investigation of Eolian Processes at Blackwater Locality No. 1, Locality X**

Locality X is a Late Prehistoric period lithic artifact scatter located within the east central boundary of Blackwater Draw Locality No. 1 (BWD) and consists primarily of thousands of very small (<1cm) lithic debitage. BWD is located in an area on the Llano Estacado prone to strong winds that could have potentially eroded, transported, and deposited the artifacts at Locality X from denser artifact deposits located upwind at the other localities of BWD. A geoarchaeological approach was used to examine the potential lithic artifact displacement by eolian processes, employing both empirical and experimental methods, including particle size analysis, wind tunnel experiments, and lithic analysis. The results showed that although the lithic artifact assemblage met some expectations for an assemblage deposited by eolian processes, the wind velocity required to entrain and transport the artifacts is greater than the velocity observed for the site; therefore, the lithic artifacts at BWD's Locality X were likely the result of cultural activities and not secondary deposition attributed to eolian processes. Locality X can be considered a primarily cultural manifestation, and stands to contribute to our understanding of human activity at BWD.

**[191] The Problem of Identity on the Motagua**

The most significant trade route for jade, obsidian, and other riches from Eastern Guatemala to the Maya Lowlands, Central America, and the Caribbean remains the least studied region in Southern Mesoamerica. This presentation describes a recent survey of the Lower Motagua and Rio Dulce river drainages, which constitutes the most complex and extensive frontier between “Classic Maya” and “Non-Maya” sites within the national boundaries of modern Guatemala. Issues of cultural affiliation associated with this cultural inter-zone are addressed in light of recent failures to characterize ethnicity in the archaeological record. Theoretical distinctions between “identity” and “identification” of local occupants are discussed vis-à-vis high-value goods that flowed through their architecturally distinct centers. It is argued, in line with past studies from Quirigua and the Lower Motagua, that the demand for prestige trade-items spurred on an unprecedented civic expansion in Eastern Guatemala during the Late Classic Period.

Hubbard, Amelia R. (Department of Sociology and Anthropology Wright State University) and Christopher M. Stojanowski (School of Human Evolution and Social Change, Arizona) [291] A Biological Approach to Identifying Kin: A Case Study from Modern-Day Coastal Kenya

The analysis of kinship is a complex endeavor. Kin can be interpreted "biologically" as genetically similar due to consanguinity, or "culturally" as spouses or partners (affinal kin) and/or close friends (fictive kin). As such, bioarchaeologists interested in kinship have a unique challenge- how to use biological datasets to evaluate an inherently biocultural construct.

The present study examines the concordance between estimates of biological kinship using paired genetic (nuclear microsatellite genotype) and dental (metric and morphological) data from 298 individuals representing four contemporary coastal Kenyan populations. Imbedded within the larger sample are four known kin groups.

Data from individuals were analyzed via cluster analysis using the CLUSTAN program, which allows users to evaluate both continuous (e.g., dental metric) and discrete (e.g., dental morphology) data simultaneously. Each biological dataset was evaluated independently and then compared to an analysis of the combined data to see if known kin groups could be identified.

Results indicate the identification of kin in archaeological contexts is quite complex and care should be used in ascribing too much relevance to patterns of dissimilarity based on phenotypic data. Though this study focuses on contemporary populations, these findings have important applications for studies of kinship in archaeological populations.

Huckell, Bruce (University of New Mexico), Duane Hubbard (U.S. National Park Service), Larry Ludwig (U.S. National Park Service), Jacob DeGayner (U.S. National Park Service) and Thaddeus Liebert (University of New Mexico) [79] Late 19th Century Apache Resistance as Seen from Chiricahua National Monument, Southeastern Arizona

Although written accounts of Chiricahua Apaches are common, few archaeological sites attributed to them have been discovered or investigated. Chiricahua subsistence was founded on hunting and gathering, but raiding, warfare, and trading provided both material goods from Mexican and American sources. Metal tools and goods, in particular, became increasingly important for Apache subsistence, and played a central role in their efforts to resist encroachment on their homelands. Since 2010, a collaborative National Park Service-University of New Mexico Colorado Plateau Cooperative Ecosystem Studies Unit project has been carried out in Chiricahua National Monument, located in the Chiricahua Mountains of southeastern Arizona. After a catastrophic wildfire in 2011, two small Apache sites were discovered after dense shrub communities were severely burned. The sites were subsequently investigated using metal detectors, mapped, collected, and protected from erosion. Recovered metal artifacts suggest that the sites date to the late 1860s–early 1870s, and include a wide array of artifact types. We use this record to explore Chiricahua Apache procurement and use of metal, and raiding, warfare, and trading as strategies to maintain their autonomy and lifeway in the face of post-Civil War American expansion.

Huckert, Chantal (Universidad Veracruzana) [62] Algunas Figuras en la Vestimenta de las Figurillas Sonrientes en el Museo de Antropología de Xalapa (MAX)

El MAX custodia una colección de “Figurillas Sonrientes” (Clasico tardío, 600–900 EC) procedentes de la tradición alfarera de las culturas de la sub-área centro-sur de Veracruz. Esta ponencia trata sobre algunas temáticas recurrentes de la imaginaria plasmada en los atuendos, que constituyen el ámbito representacional de las figurillas, en su mayor parte instrumentos musicales, portadoras de un vocabulario o más modestamente de un registro simbólico que comunica, informa, sobre la calidad social y religiosa de los protagonistas a los que representa y a traves de ellos, sobre referentes simbólicos propios de esas

[104] Comparing Fishing Strategies on the North Coast of Peru: Gramalote and Cerro La Virgen
Vertebrate remains from midden contexts at two north coast sites are compared, with a special focus on fishing strategies. The sites are Gramalote, dated to the Initial Period and interpreted as an autonomous fishing village, and Cerro La Virgen, dated to Chimú-Inca times and interpreted as a town of mixed economic pursuits embedded in a regional polity. Fishing strategies are presented within a framework of ranked goals, allowing exploration of both ecological goals (via ranked energetic efficiency) and social goals (contrasts of family autonomy versus community interdependence). Ethnoarchaeological research with modern Peruvian reed boat fishermen is incorporated in the ranking models.

Huffer, Jennifer (University of Washington)
[271] Settling Down? Understanding Patterns of Mobility in Highland Papua New Guinea through Chronology and Lithic Reduction
Models of subsistence change and the transition to agriculture for the highlands of Papua New Guinea often imply a concurrent and gradual increase in residential sedentism. However, it is not clear that a model of continuous increase in residential sedentism matches the archaeological record. While standard archaeological analytical methods such as typology of stone tools have often provided insight into changes in subsistence and mobility, the informal flake and core-based technology of the New Guinea highlands is not as tractable to these canonical methods as collections with more formal components. This paper will discuss new results from luminescence dating and measures of lithic reduction intensity—lithic analysis strategy suitable for informal collections—to evaluate models of changes in residential sedentism linked to environmental variability and the adoption of agriculture from the late Pleistocene through the Holocene.

[248] The Wallace Site: Caddo Rock Art in Southeastern Colorado
The Wallace complex includes a 12th-13th century hamlet of rectangular lodges, situated on a bluff near Pueblo, Colorado, and a rock art site below the bluff, connected to the hamlet by a midden of ‘ritual refuse’. This complex can be attributed to the Upper Republican taxon, and so the people were most likely Northern Caddoan. We use Pawnee ethnography as a general representative of this larger linguistic group to reconstruct the spatial distribution of artifacts and rock art in the chamber. The chamber itself was divided into a West Unit that contained shield-bearing warriors associated with dreams and visions that in turn provided supernatural power for low-level warfare. In contrast, an East Unit emphasized geometric images that most likely referred to the cosmological origins of humanity. This dual organization indicates that the West Unit was associated with doctors and the East Unit with priests.

[301] Breaking the Ingot Out of the Mold
This poster presents the analysis of the UCSD Levantine Archaeology Laboratory collection of ceramic molds used in the casting of copper ingots, recovered from Khirbet Hamra Ifdan, an Early Bronze II/III (ca. 3000-2000 B.C.E.) site in Southern Jordan. Useware damages in this collection include fragmentation, thermal stress, and production faults, presenting unique data for ceramic study. Through analysis of...
these features, we have attempted to identify the level of standardization in ingot and mold formation. Molds produced at KHI reveal a high degree of ceramic variability, in shape and composition. However, the standardized form of the crescent ingot impressions, and high degree of mold fragmentation, point to a unified manufactory process at this site. Analysis of the ceramic matrix has revealed the possible “engineering” of ceramic faults related to purposeful fragmentation of the casting mold. Through this study, we have attempted to define the craft techniques in use at KHI, and the relationship of these craftpersons within the greater copper industry of the Early Bronze Southern Levant.

[198] Borderland of Empires: Western Georgia and the Southern Caucasus in the 1st Millennium B.C.E.
The study of borderlands is essential to understanding the development of polities such as states, kingdoms and empires. More than just giving definition to the edges of polities, borderlands often become the focus of political ideologies and give justification to the limits of a polity’s power. In the 1st millennium B.C.E., Western Georgia found itself on the margins of the socio-economic spheres of larger, more developed polities from the Mediterranean, Russian Steppe and Southwestern Asia. Though a geographically isolated borderland, Western Georgia was deeply entangled in the larger economic and political spheres it bordered. This paper presents the archaeological evidence for the emergence of social complexity in Western Georgia in the 1st millennium B.C.E. in the context of borderland studies. Much has been made of the development of a state level polity in Western Georgia owing to four key archaeological indicators: 1) emergence of extreme wealth inequality, 2) production of coinage, 3) settlement stratification and hierarchy, and 4) similarity of archaeological material across the region. Rather than showing evidence of the emergence of a state level polity, it is shown that these changes were the result of borderland processes brought on by increased socio-economic entanglement with larger polities.

Hughes, Richard

[287] Obsidian Provenance Studies in California and Great Basin Archaeology
Since the inception of instrument-based analyses in the middle 1960’s, research conducted on obsidians erupted in California and the Great Basin has played an important role in the overall development of worldwide provenance studies in archaeology. Early work in California and the Great Basin focused on chemical identifications of archaeologically-significant obsidian which were then employed through artifact analysis to sketch the broad outlines of “exchange networks” in prehistory. Since these early days there has been growing sophistication in archaeological uses of provenance data, including more explicit awareness of the interpretive differences attending viewing of obsidian “sources” as geochemical vs. spatial entities, appreciation of the importance of segregating material by artifact class for analysis, and more sober considerations of the complexities involved in inferring the behavioral mechanisms responsible for observed distributions. All of these recent changes have contributed to the maturity and development of more anthropologically informed research agendas for obsidian provenance studies.

Hull-Walski, Deborah (Smithsonian Institution)
The National Park Service and the Smithsonian Institution: Partners in Salvage Archaeology

The River Basin Surveys (RBS) of the Smithsonian Institution and the Interagency Archaeological Salvage Program (IASP) began more than 60 years ago as an "emergency" program of archaeological reconnaissance, testing, and excavation in response to the nation's initiative to develop water resources throughout the 48 contiguous states. Under the IASP, the work of the RBS was augmented by the coordinated efforts of scores of colleges and universities, museums, and historical and archaeological societies, in conjunction with the National Park Service (NPS). The RBS assumed major responsibility for field investigations and providing scientific oversight and personnel. The primary role of NPS was as liaison between the construction agencies, cooperating institutions, and the RBS. As a result of the programs work, an estimated 20,000 sites were recorded and over 500 major excavations were conducted to further document significant prehistoric and historic sites prior to inundation. From California to Virginia, field workers collected over three million artifacts and specimens. The RBS and the IASP contributed in innumerable ways to the advancement of knowledge about America's archaeological past, and to the growth of American archaeology as a discipline.

Geoarchaeology of Urban Sediments and Soils

In New York City, urban development and land-building have some notable consequences for CRM efforts. These processes lead to rapid sedimentation, which preserves archaeological resources deep below the surface. Additionally, urban sediments and soils can convey valuable information about past landscapes and the transition from a rural to an urban environment, even when structural remains and artifacts are absent. To illustrate these points, we present a current case study from Manhattan.

Analysis of Dorsal Scar Patterns in 3D on Experimental and Middle Paleolithic Debitage

Flake scar directionality has been analyzed to determine how cores are rotated during reduction and production of flakes. Previous studies used two-dimensional directional data to infer reduction technology and how core treatment changed during reduction. This study treats the directionality of scars in three dimensions, allowing directionality to be assessed as a continuous variable, rather than categorical. Approximately 400 flakes from Tabun Types C and D from Jelinek's excavations of the Middle Paleolithic site of Tabun, Israel, housed at the University of Arizona, were scanned using a NextEngine Desktop 3D Scanner HD. These artifacts were compared with experimental assemblages representing different reduction methods (bifacial, levallois, blade, and discoidal). Flake models were produced using Rapidform XOR/XOV software. 3D vector data were taken for readable scars over 0.5 cm. This study characterizes rotational (strike or azimuth) and convexity (dip or inclination) data separately, with the aid of a visualization method called an equal area stereonet frequently used in the geosciences to study the three dimensional orientation of folds and faults, crystallography, and paleomagnetic directional data. These data allow for the comparison of assemblage level variability in directionality between different types of core reduction as well as diachronic change in the Tabun assemblages.

Hunt, Alice (University of Georgia) and Robert Speakman (University of Georgia)

Protocol for the Analysis of Archaeological Ceramics and Sediments by pXRF

Recently, there has been significant interest in the use of portable x-ray fluorescence devices (pXRF) for cultural materials applications, especially ceramics and sediments. Although modern instruments have lower detection limits and better resolution than those of decades past, portable instruments are subject to the same limitations of all ED-XRF instruments, particularly with respect to sample preparation, instrument calibration, and ability to accurately quantify low-Z elements. We have developed an analytical protocol for the accurate and precise pXRF analysis of archaeological ceramics and both as prepared samples and field specimens.

[22] **Tended and Untended Resources, Facilities, and Technologies for Plant and Animal Fibers**

Food-getting technologies can be understood as time and resource choices made by different societies. The same approach can be applied to craft-getting technologies because they run alongside and interweave with food choices. Many resources offer both food and craft possibilities and the choices made in one sphere will have direct consequences in the other. Thus the shift from collected to farmed resources for food could be expected to affect strategies for the production of fibers for crafts directly. Movements around a landscape and the seasonality of resources would also create constraints in obtaining craft materials, and then storing and working these into finished items. Wild, tended, and farmed resources can contribute to fiber crafts in complex ways. In this paper, I use ethnographic data from the Pacific NW coast, Mongolia and California to apply ideas to comparative studies of Mesolithic and Neolithic communities in Central and Northwest Europe. Particular attention is paid to different technologies for processing fibrous plants such as tree-bast fibers and nettles that can be retted in water, or processed manually and the way in which collected, plucked and shorn animal fibers likewise offer different qualities and possibilities.

[140] **Material and Social Capital at Postclassic Calixtlahuaca, Mexico**

Archaeologists have developed a number of different methods for measuring household wealth, including production step indices, measures based on the frequency of imported goods, and measures based on the evidence for particular activities, such as bowl/jar ratios. At the Middle-Late Postclassic site of Calixtlahuaca in Central Mexico, these three classes of wealth measurements produce widely differing results. These varying patterns suggest that the occupants of the site shifted the ways in which they chose to invest household capital over time, coming to favor increasingly larger events stressing non-local connections.

Hutson, Scott (University of Kentucky)

[143] **Masculinities, Symbolic Violence, and Ritual among the Postclassic Maya**

Ancient Maya leaders commonly legitimized their authority and gained prestige by taking captives on the battlefield. Though women occasionally went to war, Maya artists represented warfare as a masculine activity, and it was through warfare and other activities such as hunting and the ballgame that a particularly athletic and embodied masculinity took shape. This masculinity became hegemonic by the Classic period, coupled with rulership and hierarchical politico-ritual authority. In the Postclassic period, power relations became more heterarchical, and alternative gender identities became more prominent in rituals. Nevertheless, the archaeological record continues to provide instances in which violent masculinities bundled with politico-ritual authority. This paper places new data from the Uci Cansahcab Regional Integration Project, located in northern Yucatan, in context with published data from other studies to discuss the play of multiple masculinities and femininities among the Postclassic Maya.

[278] **Leading a Horse to Water: Hominin Activities at the Schöningen 13II-4 “Spear Horizon”**

Preliminary results of a new taphonomic analysis of the large mammalian faunal remains from the Schöningen 13II-4 “Spear Horizon” reveal an accumulation of more than 50 horses within lakeshore
deposits dated to roughly 300,000 years ago. Age and sex profiles of the horse population suggest multiple hunting episodes by Middle Pleistocene hominins. The remains of several other large herbivore species, primarily cervids and bovids, further attest to a more prolonged duration of accumulation rather than a single, mass kill event. The lakeside setting likely attracted large herds of ungulates, and in turn, served as a fitting location for ambush hunting by Middle Pleistocene hominins and other large carnivores. Systematic processing of animal carcasses is clearly indicated as the entire sequence of butchery is preserved, from filleting and disarticulation to the preparation of bones for marrow extraction. Also present is the widespread use of bones for the manufacture and resharpening of stone tools, including bone retouchers, soft hammers, and anvils. Further multi-proxy analyses are scheduled to explore the unique archaeological record at Schöningen and to provide a context for the functional organization of hominin behavior and adaptive mechanisms to Pleistocene interglacial environments in Europe.

Iannone, Gyles (Trent University) [235] From Pyu to Toungoo (A.D. 200-1599): Modeling Resilience in the Early State Formations of Myanmar/Burma

Adaptive Cycles and Panarchy Theory have recently emerged as key tools in the transdisciplinary examination of resilience and vulnerability in coupled socio-ecological systems, past and present. These analytical frameworks are, however, only heuristic devices, and specific case studies need to be examined in great detail, using a diachronic perspective, in order to highlight congruencies and divergences from the ideal expectations of these models. It is only through this means that archaeologists are able to generate a more comprehensive understanding of the factors involved in the formation and dissolution of particular complex adaptive systems. The ways in which different case studies map onto the expectations of the ideal models can then be compared using the bundled continua of variation approach in order to advance our general understanding of resilience and vulnerability in past communities. This broader perspective ultimately allows archaeologists to make some suggestions regarding how we might proactively address similar issues in the contemporary world. The rise and fall of various early state formations in Myanmar/Burma are used to illustrate these various points.

Ibarra Asencios, Bebel [38] Funeral Traditions in the Peruvian North Highlands during the Late Intermediate Period (A.D. 1000-1500): Perspectives from the Marcajirca Site, Huari, Ancash

The site of Marcajirca is located in the province of Huari–Ancash, in the Peruvian north highlands. The site has a long occupation sequence dating to between A.D. 1020 and 1640 A.D. Marcajirca contains one of the largest quantities of funeral structures in the entire region. At present, archaeological investigation has identified about 35 tombs and 21 funeral caves. The excavation in chullpas and caves combined with
radiocarbon dates has revealed a reuse of the structures over a long period of time. Osteological study suggests that the minimum number of individuals shows that multiple individuals were interred in the tombs. Furthermore, congenital deformities suggest that the individual were biologically related. The presence of at least two types of skull deformation makes Marcajirca interesting for understanding the nature of group ethnic identity before the Spanish times.

Ichikawa, Mitsuo (Center for African Area Studies, Kyoto University)

[73]  *Marks on the Landscape for Reconstructing the Past among the Hunter-gatherers in Central Africa*

While the Pygmy hunter-gatherers in Africa marked the landscape often "unintentionally," they extract various "meanings" from the resulting landscape. For example, when they clear the forest to build a camp, the vegetation changes, and such a site can be identified even after several decades from its abandonment. They put to each camp site a specific name, which often derives a large tree standing nearby, a stream from which they fetch water, or the name of a certain person, and remember well the locations of these old campsites. With these camp names, they clearly remember the past events: who were born, died, got sick at these camps, for example. Old campsites are in this way used as reference points for reconstructing their history. Without such references, they may find difficulty in keeping memories of their life history and past events. With old campsites and other human-made marks on the forest landscape, they articulate their past experiences, which might otherwise have been obscured in the monotonous time flown seamlessly. I will describe different types of marks made on the landscape by the Mbuti Pygmies, and discuss the "meanings" they convey to the Mbuti.

[311]  *Earliest Panamanian Pottery (ca. 4,500-3,200 14C yr B.P.): Sedentism and Circulation Patterns*

Following the abundant evidence of agriculture, archaeologists have argued whether the oldest Panamanian pottery, Monagrillo (ca. 4300-3200 14C yr B.P.), emerged among agricultural communities with a high degree of sedentism, or farmers who retained some level of seasonal residential mobility. This study assesses this question by studying the production and circulation of Monagrillo. Pottery and raw materials were examined using petrographic thin sections and geochemistry, laser ablation-inductively coupled plasma mass spectrometry, and portable XRF. The results suggested that pottery was produced on the Pacific side of the northeastern Azuero coast and Pacific foothills near Parita Bay. Pacific foothills pottery was transported to the Caribbean slope. Both Pacific foothills and Azuero produced pottery circulated to the Pacific plains site. It is interpreted that people of sedentary pottery producing communities around Parita Bay often visited the Pacific plains site, carrying pottery. They preferred to make vessels in the seasonally driest Parita Bay area. They transported Pacific foothills vessels to the Caribbean foothills because the Caribbean side of central Panama is almost perennially wet, and that condition is not optimal for pottery production.

[150]  *Political Change at the End of the Formative Period: A View from the Nepeña Middle Valley*

This paper presents preliminary results of a full coverage pedestrian survey of the middle section (Moro Pocket) of the Nepeña River valley carried out in 2012. The archaeological data obtained by a systematic collection of surface material is confronted with the expectations of current hypotheses explaining the drastic sociopolitical changes occurring at the end of the Formative Period after the disintegration of the Cupisnique-Chavín religious complex. By the exploration of demographic and architectural patterns I reconstruct the trajectory of political change in a restricted area of 89 km2 between the first millennium B.C. and the first several centuries of the Common Era.

[29]  *Climate Extremes for Archaeologists*

Extreme climate events are frequently cited as causal factors in social transformations and changing human trajectories in the archaeological and historical record. Given the explanatory potential of these extreme events, systematic methods of identifying, describing, and comparing climate extremes across
time and space are required. Without such methods and descriptions, climate-human behavior studies cannot investigate why some climate events are temporally associated with changes in human behavior while other events (perhaps similar) are not. Arguments about climatic influences on human history will be more convincing if robust examples of human responses to clearly identified extreme climate events can be offered. In this presentation, a methodology for extreme event identification in the contrasting climatic regimes of the North Atlantic and U.S. Southwest is presented. The approach was developed for non-specialist users of paleoclimatic data, especially those interested in potential human responses to climate extremes. A simple method of identifying how “surprising” an event may have been for people as well as quantitative descriptions of climate extremes (e.g., duration, magnitude, intensity) will be presented. The purpose of the presentation is to stimulate and advance systematic causal investigations of climatic impacts on human behavior with long-term climate and human behavior datasets.

[128]  *Interaction between the Maya Lowlands and the Isthmian Region during the Middle Preclassic Period*

Recent investigations at the lowland Maya site of Ceibal revealed substantial evidence of interaction with groups occupying the Grijalva River basin in Chiapas and the areas beyond. The available data point to close connections among diverse groups. For studies of the Preclassic period, we should not impose or presuppose ethnic or cultural boundaries seen in later times. Instead, we need to examine how diverse identities are created and negotiated through actions of individuals and groups who participated in these webs of interaction.

[178]  *Symbolism of Shark Teeth in Olmec Iconography*

The shark is one of the most common animals in Olmec iconography. Although the Olmec artists are proficient in naturalistic expression, the Olmec shark is always highly stylized and standardized and often fused with other animals and deities by taking advantage of pars pro toto principle. While its frequent occurrence in the Olmec art suggests the importance of the Olmec shark in their religion, little is known about the meaning, symbolism and functions. In this presentation I will focus on the shark tooth motif marked in the celtiform maize ears to investigate the role of the Olmec shark. Archaeologists have long interpreted shark teeth as major paraphernalia for bloodletting rituals; however, I will argue that symbolism of shark teeth is more than a bloodletter. The shark tooth motif in the cardinal celtiform maize ear represents a v-shaped overlap of maize husk and the eye of the personified maize ear. For the Olmecs, shark teeth are strongly associated with the maize cult and clearly played a key role in the development of the cosmology, which also influenced later Mesoamerican religion.

[143]  *Fierce Killers of the Wari Empire: Professional Soldiers or Real Men?*

Trauma is frequent among the skeletal remains of Wari citizens, revealing a high level of violence during Peru’s Middle Horizon. Iconographic representations of armed men associated with aggressive animals, appear in ritual contexts, implying high value on hostility. Humans were decapitated and body parts, especially heads, were processed into ceremonial objects, perhaps war trophies. Scholars have argued that these data document the emergence of warrior associations – constituting a military “class” of hierarchically organized specialists consistent with a V. Gordon Childe model of activity professionalization during Peru’s Urban Revolution. However, examination of how gender was
represented in the Andean past implies a long tradition of contrast between male and female identities that sheds a different light upon the iconographic data. Perhaps more than a professional military class, what promoted the apparent increase in militaristic violence was a redefinition of masculinity—and surely femininity as well—idealizing Wari men as fierce and bloodthirsty warriors who killed and maimed in order to display their manhood.

[75] Past Amazon and Future Earth
Archaeological and anthropological research in the Amazon region over the last two decades have fundamentally reshaped our understanding of human-environmental relationships and early social complexity in the Neotropics, and continue to offer major stimuli for the ongoing development of historical ecology as a poly-disciplinary research program. In this paper, we summarize some key insights the revised paradigm of the Amazonian past and cultural landscape generate on resilient and sustainable resource management that are both regional and global in scope. We focus on pre-Columbian soil management practices enhancing soil nutrient holding capacity and the cultural management of biodiversity in the Neotropical landscape, emphasizing the study of long-term social-ecological processes, applications of historical ecological research results, and the impacts of these lines of investigation in changing the broader human/environment discourse.

Ives, John (University of Alberta)

Our current interdisciplinary research concerning the Promontory Caves in Utah is focused upon assessing whether or not Apachean ancestors created the Promontory Phase deposits there, as Julian Steward suspected. Yet, the abundance of perishables in the caves is extraordinary even by Great Basin standards. Matters of cultural identity and the abrupt shift in material culture that accompanies the Promontory Phase should not overshadow efforts to answer a range of anthropological questions limited only by our imagination. Steward proved remarkably prescient in his 1930s work in two other respects: estimating the age and duration of the Promontory occupations and assessing the economic focus of the cave occupants. More than 80 AMS dates allow us to show that Promontory Caves 1 and 2 were intensively occupied over a period of one to two human generations ca. A.D. 1240-1290. Equally striking are the evidence for heavy reliance on large game, especially bison, with the virtual absence of evidence for seed processing. Ceramic geochemistry, carbon isotope data, obsidian sourcing and rock art reveal an array of external, sometimes distant interactions. Moccasin size data permit demographic inferences about the Promontory Caves population structure with a precision even mortuary records cannot match.

[341] Sociocultural Resilience to Natural Disasters: A Case Study of the Aztec 1506 Drought
This paper examines an archaeological example of sociocultural resilience to natural disasters by analyzing functions of some major Aztec monumental sculptures related to the 1506 drought. The Aztecs (A.D. 1325 to 1521) recorded in their historical accounts that large-scale droughts occurred every 52 years, which accords with the Aztec traditional calendric cycle. These repeated abnormal weather events have been also attested scientifically by the recent tree-ring analyses. Among the historical droughts those of 1454 and 1506 are the best described in Aztec pictorial manuscripts, Colonial documents and archaeological remains. The year 1454 corresponds to the reign of Motecuzoma I, who, in spite of the fatal damage to the kingdom caused by the disasters, successfully reinforced the political-economic influence of the kingdom over the city-states outside the Basin of Mexico by invading fertile regions, modifying religious practices to justify the militant strategies, and developing technologies in building aqueducts and chinampas. His grandson, Motecuzoma II, who experienced the 1506 drought, not only followed the strategies of his antecedent but also created some monumental sculptures to mythically commemorate both the disaster and victory of the kingdom. These monuments might have a
sociocultural function to reconstruct and repeatedly share the Aztec environmental cognition.

[227] La importancia política de las unidades mayas de parentesco en un sistema de gobierno heterarquico en la época Clásica
Esta ponencia tiene como objetivo mostrar que la organización política maya del Clásico tardío se puede conceptualizar como heterarquica. Por ello las formas de gobierno al interior de las comunidades eran mixtas, es decir había una línea de mando vertical, que ahora ha sido detallada por epigrafistas, arqueólogos e historiadores del arte y una línea de mando horizontal desarrollada en los grupos corporativos, cuyas formas de autoridad y maneras de funcionamiento están por descubrirse. Por ello para desentrañar sus características, además de analizar los datos arqueológicos a la luz de nuevas teorías sociales, se alude a los rasgos de los grupos de parentesco, que aportan la etnohistoria y la etnología.

[102] Bioarchaeology, Nutrition, and Urban Food Systems in Roman Britain: A Rural Perspective
The current analysis centers on nutritional health status, bone robusticity, and dental health in skeletal remains (n = 73) from excavations of a rural Romano-British population at Alington Avenue, Farington, Dorchester (A.D. 43-410). By comparing my results to those from other contemporaneous urban and non-urban populations, I discuss nutrition and social difference among Romano-British populations and suggest that the Alington Avenue population experienced relatively good nutrition. I conclude that it is possible that Farington’s place as an early farming population with an economy derived primarily from its role in the rural food economy and distance from large urban centers (e.g., coloniae) allowed its citizens to more easily fulfill their nutritive needs.

Jackson, Sarah (University of Cincinnati)
[164] Classic Maya Material Meanings (and Modern Archaeological Consequences)
Ideas about materiality and the material world are variable and locally created, and include culturally-defined assumptions about how the world is organized (e.g., the division between humans and objects). For the Classic Maya of southern Mexico and Central America (ca. A.D. 250-900), we have clues about the distinctive views on the material world that they embraced (e.g., at times attributing personhood to material objects); however, to date we have lacked the details of their cultural model of the material world. This paper proposes a new reconstruction of details of a Classic Maya worldview on materiality, derived from primary source epigraphic and iconographic evidence, with an emphasis on the organization and boundaries of what are considered culturally-meaningful materials, and the relevant qualities thereof. This reconstructed worldview suggests ancient indigenous perspectives on excavated materials, changing our understandings of materials, focusing modern attention on salient qualities of recovered objects, and yielding an ability to describe human-object and object-object networks of relationships. The results of this reconstructed worldview offer innovations in terms of both theoretical models and practical/methodological archaeological approaches, paving the way for transformations in the field in the inclusion and synthesis of multiple perspectives, voices, and types of evidence.

[260] Tracking the Mississippian Period in the Lower Yazoo Basin: Results of Mound Testing by the Mississippi Mounds Trail Project

The Lower Yazoo Basin of the Lower Mississippi Valley is postulated to encompass a relatively unitary cultural expression, a conclusion largely based on investigations at the two primary mound centers of the region, Winterville Mounds at the northern end of the basin and the Lake George site in the southern portion. However, there are a number of smaller Mississippian mound centers dispersed along the modern Mississippi River course as well as scattered along one of the main interior waterways, Deer Creek. These minor sites are largely represented by surface collections, these mainly being the product of Philip Phillips survey of the 1940s and published in 1970. In his assessment of these collections, Phillips hinted at a possible cultural division between north and south, one that the available data could not clearly substantiate. Recent testing of a number of key minor mound centers between Winterville and Lake George, afforded by the development of the Mississippi Mound Trail by the Department of Archives and History provides a fresh opportunity to examine both cultural and chronological patterns in the Yazoo Basin during the Mississippian period.

[320] Subsistence, Culture, and Environment: Faunal Analysis of the Fish Creek Slough Site (41DL436)

The Fish Creek Slough Site (41DL436) was identified during TxDOT's cultural resources assessment of a proposed transportation project in Dallas County, Texas. The deeply buried, well-stratified site dated from approximately 1270 A.D. to recent historic times. While a paucity of lithic artifacts were noted during data recovery efforts, over 8700 well-preserved bone fragments were recovered and analyzed by TRC. Approximately 5 percent of the bones recovered were unbroken and over 53 percent of all bone, including that recovered from heavy fraction, was identifiable to class, marking it as one of the best-preserved archaeological faunal assemblages recovered from North Texas. Shifts in species presence and availability, notably bison; human modification of bone; and technological changes in butchery and hunting tools from the late prehistoric to protohistoric to historic periods are examined.

[331] Land Recognition, Identity, and Diverse Understandings of Materiality: Archaeological Practice in a “Quilombola” Community, Brazilian Amazon

Researchers during fieldwork have commonly been facing situations that challenge our understanding of archaeology as a science that investigates the past. Local communities and different publics through their demands and traditional ways of living call our attention to different ways of understanding the world and interpreting heritage. Through people’s daily activities and materialities involved in local practices we can think of archaeology as strongly connected to the present. This presentation aims to discuss approaches that include reflexivity, dialogue, and respect for cultural diversity based on doctoral research that is taking place at an African American community in the Amazon region called Comunidade Quilombola de Cinco Chagas do Matapi. This community is located in a place with archaeological finds related to indigenous and African American history of the Amapá State. Issues about land recognition and identity lead us to a diverse understanding of contemporary materiality and landscape. It is questioned how archaeologists can engage in a collaboration that makes sense to local communities in the context of the Brazilian Amazon region.

[304] Minimum Requirements: Experience and No Expectations?

For a growing generation of young Cultural Resource Management (CRM) professionals, the catch-22 of
the typical CRM job description can seem unnecessarily daunting. With minimum requirements for supervisory experience and technical expertise, many “new” professionals are as frustrated as the potential employers that cannot seem to find the workforce they require. Providing multiple opportunities for archaeological internships and fieldwork experience, PennDOT is one of the too few employers to explore the different ways to foster the type of potential employees they require for their continued practice in CRM. PennDOT’s central office-based internships and PennDOT Highway Archaeological Survey Team (PHAST), an internally-operated PennDOT archaeological survey crew staffed by graduate and undergraduate students, are two examples of innovative approaches by employers at mentoring and developing a new generation of CRM practitioners, while also providing an invaluable and cost-effective service to the state government and ultimately the public. By taking advantage of opportunities like PHAST and other internship programs, the next generation can begin to prepare itself for its “coming of age,” as it heads into the familiar, yet ever-changing future of CRM.

[140] Deer Species at Mayan Postclassic Mayapán  
Two species of deer (Cervidae), white-tailed deer (Odocoileus virginianus) and brocket deer (Mazama americana) have been identified in the Mayapán faunal assemblage. The size range of the osteological remains from these two deer species does not overlap, resulting in the accurate identification of faunal remains from archaeological contexts. Previous faunal analyses found that some deer bones recovered from Mayapán were of an unexpected size that was between the size ranges of brocket and white-tailed deer. This study used metrical and statistical analysis of Cervidae long bones recovered during excavations in 2008 and 2009 as well as the mortality profile of the sample based on epiphyseal suture closure to determine the presence of a third deer species at Postclassic Mayan Mayapán.

[301] Comparing Methods of Enthesis Analysis: An Example from Early Neolithic Iran  
Traditionally, lesions at the site of muscle attachment (enthesopathies) have been interpreted as musculoskeletal stress markers, and as evidence of specific occupations in past populations. Rather than being an indicator of specific occupation, present consensus focuses on identifying correlations between repetitive motions and high frequencies of lesions. The present study investigates the relationship between gender-based activity patterns and enthesopathies using a skeletal sample of 23 individuals from Ganj Dareh Tepe, a Neolithic village site of sedentary pastoralists in the central Zagros Mountains of Iran, ca. 10,000 BP. The methods of visual, tactile and fractal dimension assessment of enthesis morphology are compared and used to assess the relationship between enthesopathy presence and sex. The entheses from the upper arm and leg are examined for size, rugosity and robusticity using metric and non-metric techniques, while fractal dimensions, obtained through NextEngine laser scanner evaluation, allow for assessment of the relative complexity of the attachment sites. The interpretive challenges and benefits of each method are compared. The sex-based differences in enthesopathy frequency and distribution patterns are discussed. These bioarchaeological data provide specific understanding of the habitual activities of individuals and the lifeways of a population during a transitional period in time.

[58] Iron Age Frontier Landscapes and Complex Societies in the Mandara Mountains (North Cameroon): Plains and Mountain Relationships  
In northern Cameroon, the Mandara Mountains provide a testimony to the geographical and cultural encounter between two worlds: mountain peoples, pagan and ‘egalitarian’, and those of the surrounding plains, living under the hierarchical control of Islamic states. Through their construction of sixteen imposing dry-stone structure, the people who built the DGB sites (13th to 16th century A.D.) developed mountain landscapes independently of influence from their powerful plains neighbors. However, several clues suggest the existence of a relationship between these two complex cultural areas. The discovery of two new mountain sites in the same area contributes new elements to our understanding of the phenomenon of monumental architecture in the Mandara region. Finally, preliminary results of comparative ceramic analysis from plains and mountain Iron Age sites provide information on the relationship that existed between these two communities.

Janusek, John (Vanderbilt University)  
[288] Centering “Complexity”: Ritual, Materiality, and Emergent Urbanism in the South-Central Andes  
The term 'complexity' is way overdue for a makeover. It is integrally tied to evolutionary narratives and is easily construed as a stand-in for its problematic conceptual partner, “civilization.” In this paper I analyze the concept of “complexity” as an abstract touchstone for evolutionary narratives. I discuss centrality and urbanism as material manifestations of what archaeologists term ‘complexity’ in the prehispanic south-central Andes. I seek to define some of the key elements of emergent centrality and urbanism in this world region. I argue that ritual practice was critical to the production and transformation of centers in the region. By ritual, I refer to charged events that gather together all sorts of activities, be they economic, political, or religious. In addition, I argue that specific material elements of built monuments, including the very material constitution of their stone facades and earthen cores, were critical to their significance and transformation. I argue for a relational and material approach to “complexity,” one that emphasizes the ritual production of proto-urban centers as anchors for emergent complexity.

[40] Moving Herds: Ancient Pastoral Mobility in Kenya Assessed through Stable Isotope Analysis  
Specialized pastoralism emerged in Kenya around 3000 years ago and has adapted with changes in the social and ecological landscape to this day. Ethnographic research has documented significant changes in herding strategies among pastoral groups throughout colonial and post-colonial periods. Stable isotope analysis can shed light on how crucial mobility was in maintaining herds before the encroachment of iron-using and --producing peoples. Intra-tooth sequential sampling of enamel of herd animals presents an
isotopic record of diet during tooth formation, and can thus track movements across the landscape. These analyses were conducted on enamel of livestock teeth from several Savanna Pastoral Neolithic sites in the Central Rift Valley and Athi Plains of Kenya. Some sites are clearly the result of specialized pastoralist pursuits, and other sites indicate a mixed economy of pastoralism and hunting-gathering. While carbon stable isotope ratios do not indicate seasonal altitudinal mobility up the sides of the escarpments flanking the Rift Valley, this does not preclude movement of livestock long distances at low elevations. 87Sr/86Sr ratios can reflect movement across geologically distinct soil complexes, thus showing such mobility. Here, analysis of the strontium isotope composition of tooth enamel provides another line of evidence for pastoral mobility.

[321] The Ceramic Dynamic: A Synthesis of Recent Research on Ceramic Production and Distribution at Three Chaco-era Great House Communities in the Southern Cibola Region of New Mexico

Recent studies of ceramic composition and technological style on the southern fringes of the Chaco regional system have revealed striking patterns in ceramic production and distribution that also shed light on community organization and regional interaction. Through these and past studies, a strong case has been made that Puebloan and Mogollon people lived together in these communities during the Pueblo II period. Settlements within this region of cultural overlap provide a unique opportunity for the study of identity and interaction along both spatial and historical scales. In this paper, we offer a comparison of studies conducted at three Chaco-era (1050-1130 A.D.) Great House communities in the Southern Cibola region of west-central New Mexico with the aim of synthesizing the results to address these patterns at the level of the broader research area. A suite of analytical methods, including visual temper analysis, analysis of elemental composition via electron microprobe, as well as low-tech analysis of technological style offer several complementary lines of evidence. Our results indicate varied patterns in plainware ceramic production and distribution at sites across the study area. These differing patterns have implications for understanding local and regional social dynamics.

Jarriel, Katherine (Cornell University)

[181] Terraces and Cycladic Social Landscapes: A Diachronic Perspective

Stone-wall terraces are dominant anthropogenic features of many Mediterranean agricultural landscapes. In the Cyclades, archaeologists often neglect the study of terraces due to unreliable dating and the assumption that they are modern phenomena (Frederick and Krahtopoulou 2000: 80). When Aegeanists do include discussions of terraces, they tend to describe morphology and function or assess dating techniques (e.g. Price and Nixon 2005; Kizos and Koulouri 2006; Frederick and Krahtopoulou 2000). A consideration of the social and ideological relationships between terraces and the agents of their manufacture offers a new perspective on this major feature of Cycladic islandscapes. This paper takes a diachronic approach to shifting land-use strategies and landscape ideologies of Cycladic populations from the first evidence of terracing (Middle to Late Bronze Age) through the 20th century, when increasing mechanization led to widespread abandonment of ‘traditional’ terracing. Aerial and satellite photography and survey data reveal the diversity of terrace uses at varying moments in history. Economic, social, and environmental factors influenced how local people acted to modify the countryside, which in turn altered their perception and experience of the landscape. An integrative approach to terraces in their social contexts promises to nuance a major aspect of Cycladic landscapes.

[73] Initializing the Landscape: Chipewyan Construction of Meaning in a Recently Occupied Environment

What happens when hunter-gatherers move into a new territory? Over what period of time, and by what means, do such people make their new environment culturally meaningful for themselves? What kinds of markings, modifications of landscape, and other conventions might be involved in this nascent process? These questions will be addressed by considering the recent history of the Kesyehot’ine group of Chipewyan, hunter-fishers of the subarctic. Prior to the mid-18th century, their ancestors had occupied the forest-tundra ecotone in what is now the Northwest Territories. By the end of that century, however, these people had moved south and southwestward several hundred miles into the full boreal forest and
along the headwaters of the Churchill River in what is now northwestern Saskatchewan. In little more than eight generation, then, the Kesye'hot'ine have adapted to a new set of biogeographical and political economic circumstances. Cultural marking or "initializing" this unfamiliar environment, arguably, involved a complex interplay of wayfinding by landscape features, construction of habitations and sites with profound social identity and spiritual resonance, and significant cognitive mapping of the landscape through oral lore linked to place names. Special consideration will be given to the emergence of a mortuary-based pilgrimage complex.

[316] Central Place Foraging and Shellfish Processing on California's Northern Channel Islands

We examine the processing and transport costs of two shellfish species collected on California's Northern Channel Islands during the Middle Holocene (7500-3500 cal B.P.), red abalone (Haliotis rufescens) and California mussel (Mytilus californianus), and how these costs can influence archaeological assemblages at coastal and interior settlements. Food resources can be processed in the field or transported back to settlements for processing and preparation. Decisions to field process may be based in part on time constraints and the ratio of meat and shell on the targeted organism. Our experimental data suggest that red abalones are less likely to be transported long distances (~3 km) without field processing. The transportation threshold is farther for California mussels based on published experimental data. Archaeological data from three Middle Holocene sites on Santa Rosa Island, SRI-50, SRI-109, and SRI-338, are consistent with these expectations. Coastal red abalone midden sites (SRI-109 and SRI-338) are dominated by large red abalone shells and California mussels are most abundant at contemporaneous inland sites (e.g., SRI-50). This study suggests that transportation and processing of costs of food resources should be carefully considered when interpreting archaeological faunal assemblages.

[30] The "Cookhouse" at the Tom Jones Site (3HE40)

In 2001, under the direction of Dr. Tom Green, the Arkansas Archaeological Survey and the Arkansas Archaeological Society began a three year project that included remote sensing surveys at the Tom Jones site (3HE40), a small fifteenth-century Caddo mound group located precisely on the divide between the Red River and Ouachita River drainages in the Grandview Prairie Wildlife Management Area in southwest Arkansas. These led to the discovery and excavation of the remains of three deliberately burned pole, daub, and thatch buildings. Two of these were probably elite residences of the type generally found at Caddo ceremonial centers. The third was a small, archaeologically unique, "cookhouse" that had stood adjacent to the single platform mound at the site and had evidently been burned with all its contents, which included over twenty pottery vessels and other ceremonial elements, still inside.

[28] Contexts, Needs, and Social Messaging: “In Situating” Iroquoian Human Bone Objects
Typically categorized as trophies, human bone objects recovered from archaeological sites across southern Ontario represent a continuous shared Northern Iroquoian tradition. Human bone was manufactured into items of personal adornment, musical instruments and utilitarian tools. Most were recovered within villages in large middens, interior longhouse refuse pits and other public spaces. My study of archaeological literature assembled an inventory of human bone objects providing detail on provenience and descriptive attributes. The rationale was to investigate human bone objects in their recovery contexts to search for temporal and spatial trends and to provide insight into cultural processes that created the assemblage. To accomplish this, I studied human bone objects in context employing two case studies of contemporary Iroquoian village sites to identify spatial trends and provide interpretative value. I discovered that human bone objects were important indicators of group identity and their disposal signified a terminating group identity, marking new alignments in the social and political structuring of the people. Whether enemy or ancestor, repositioning human bone objects within a broader contextual framework, as opposed to standalone artifacts, allows a more holistic explanation as to why some Iroquoians were deposited in a context considered set apart from “normal” burial practices.

[168] A Tale of Two Villages: Considering Land Tenure in the Spanish and American Periods

When attempting to explain the layout and distribution of settlements, archaeologists often consider geographic limitations, economic needs, and the enduring influence of cultural traditions. A fourth factor—one that may be irrelevant in prehistory but is inescapable in the historical period—is the role of land tenure laws. The influence of these laws is especially evident in the Southwest, where settlements were established during periods of Spanish, Mexican, and American rule. This paper considers the roles of new laws and old traditions in shaping two Hispanic New Mexican villages—one established by a Spanish community land grant, and the other settled by homesteading families.

[24] Paleoindians in Central Texas: Research at the Debra L. Friedkin and Hogeye Sites

The North Star Archaeological Research Program, created by Joe and Ruth Cramer, has recently supported research at two sites in Central Texas that are providing new insights into Paleoindian archaeology. The Debra L. Friedkin site has yielded stone tools and debitage associated with Pre-Clovis, Clovis, Folsom, and Golondrina occupations. At the Hogeye site, one of the largest Clovis biface caches discovered to date has been found and documented. Through analyses of these collections, we are addressing the question of Clovis origins, identifying regional Clovis technological and adaptive signatures, and tracing changes in post-Clovis Paleoindian technologies.

[68] Nuvuk, Walakpa, and Beyond: Heritage and Archaeology on the North Slope of Alaska

This paper uses recent projects in the Barrow area of Alaska as examples of interaction between the archaeology community and the broader public. The Nuvuk Archaeology Project began in 1998 at the request of the local community and provided opportunities for high school students to participate in archaeology at a rapidly eroding village. The Walakpa Archaeological Salvage Project was initiated in 2013 when a structure was found eroding at Walakpa, causing local concern. Timing made students unavailable, but the expanded use of volunteers to stretch limited funds for a crew was successful. The Inupiat Heritage Center also provided a staff member as part of the crew.

These projects include extensive public engagement efforts. Public and classroom talks are standard, but recent efforts go much further. Large segments of the North Slope community are keenly interested in their heritage, but lack time to participate directly in excavations or preservation efforts. Many people are fascinated by the Arctic. A combination of traditional print, broadcast and new media, including Facebook Groups and Pages, a blog and Twitter is proving to be particularly useful in reaching and engaging these
groups.

Jeremiah, Kristen (SWCA Environmental Consultants)
[232] The Archaeology of Fort Travis
Located at the western tip of the Bolivar Peninsula, Galveston County, Texas, Fort Travis is the best preserved coastal military fortification along the Gulf Coast. Active in WWI and WWII, protecting the inlet to Galveston Bay, Fort Travis accommodated troops and interned German prisoners of war. The fort is listed on the NRHP under criteria A and C and is designated as a Texas State Antiquities Landmark. Recent investigations conducted by SWCA Environmental Consultants (SWCA) include metal detecting, subsurface testing, and a thorough inventory of remnant structural features, including 12 concrete building foundations, two water tanks, four batteries, an observation tower, an anti-aircraft gun emplacement, the caretaker’s residence, the Old Hwy 87 brick road, and the seawall constructed following the Great Storm of 1900. This poster presents the overall results of SWCA’s investigations including features and artifact assemblages identified within the fort.

Jeske, Robert (University of Wisconsin Milwaukee) and Katherine Sterner Miller (University of Wisconsin Milwaukee)
[255] Microwear Analysis of Bipolar Tools from the Crescent Bay Hunt Club Site (47Je904)
The Crescent Bay Hunt Club site is an Oneota village, occupied ca. A.D. 1200-1400, near Lake Koshkonong in Southeastern Wisconsin. Microwear analysis of a sample of artifacts from Crescent Bay has demonstrated that, in general, morphofunctional typology has limited value for the assessment of tool function at that site. Triangular artifacts commonly called “Madison Points” sometimes show hide scraping, cutting, and other use wear. Nonretouched debitage commonly shows evidence for hide scraping. One variable that may impact tool use is the method of manufacture and consequent constraints on tool form and size. In this study, both low power and high power microscopy are used on several morphological variants of bipolar tools, including cores and/or pièces esquillées, to determine if a bipolar manufacturing origin is correlated with tool function and/or use at the site.

[120] Ritual Processions in Ancient Tollan: The Legacy in Stone
The many sculptural images which are conserved in the ancient city of Tula indicate the existence of at least two types of ritual processions led by kings or nobles, priests, and warriors. Depicted in stone, the processions were placed in buildings of the sacred precinct, which are located on the highest points of the ancient settlement, thus giving the sculpted processions great symbolic value. A specific type of sculpted procession seems to represent personages who have participated in very emotive events (such as military conquests) which were celebrated with the exhibition of the warriors, their weapons, and their uniforms to the public in the principal plaza. Another procession group appears to be composed of symbolic personages, such as warriors who are being transported on the backs of feathered serpents. In these processions, the serpents are probably guides and protectors.

[128] Fluid Boundaries and Shifting Frontiers: Reflections of the Middle Usumacinta
The Maya sites of Chinkihá, Pomona, Yaxchilan and Piedras Negras, located along the margins of middle Usumacina, generally are considered polities of the Late Classic Period that conceptually mark the boundary between the western lowlands and the “Petén Usumacinta”. However, certain ceramic materials, specifically those common classes, express a changeable mosaic of social, economic and political interactions. Sometimes, these utilitarian ceramic classes can be seen as similar across a wide area. At other times, however, depending on the subclass, properties of form, decoration or paste may be highly variable, elaborating or simplifying according to the specific sociocultural environment and the analytical methodology used in the investigation. A critical question addressed in this paper is whether or not it is possible, based on the pottery, to discern boundaries among the sites considered or between the “Western Lowlands” and the Central Petén. To address this question we discuss the ceramic parameters
that might be used to infer a shared ceramic cultural tradition by these polities and those that differed at various times according to local histories of these riverine Maya centers.

[339]  Aztatlán: Inroads on Its Encroachment

Thirty years after J. Charles Kelley’s seminal paper "Hypothetical Functioning of the Major Postclassic Trade System of West and Northwest Mexico" was presented in the XVII Mesa Redonda of the Sociedad Mexicana de Antropología in Taxco 1983, returning Aztatlán to attention, significant advances have been made concerning its highland manifestations in both the West and Northwest. This presentation will focus on the recent archaeological excavations in the Cerro del Teul in southern Zacatecas pertaining to Aztatlán’s Early and Late Postclassic components and compares them with neighboring regions. The concluding section will assess the present evidence for Kelley’s proposed Aztatlán connections to Tula via Jalisco and Michoacan, while considering an alternative nexus to the Valley of Puebla-Tlaxcala and the Mixtec regions through the Balsas Depression.

[192]  Let the Fishes Speak: Prehispanic Maya Fisheries in Xcambó, Yucatán, Mexico.

The relationship between humanity and the sea during prehispanic times in the Maya area is well supported through iconographical and ethnohistorical sources. However, the nature and importance of fish resource exploitation during the Classic Period (250-900 A.D), the apogee of Maya history, remains largely unknown. This paper presents evidence of fish remains recovered from Xcambó (250-750 A.D), an important commercial port located on the north coast of the Yucatán peninsula. Fishing efforts in Xcambó were oriented to catching sharks, snook, and catfish, using particular fishing methods, and they represented an important part in the diet of the ancient Maya. Although it has been proposed that marine resources, including fish, could have been traded and transported from coastal to inland localities, evidence from Xcambó indicates that fishing was an important local subsistence activity.

[92]  Echoes in Eternity: Stone Monuments and Social Memory in Bronze-Iron Age Mongolia

Funerary monuments are constructs that by their very nature are vehicles for commemorative narratives. Moreover, social memory is typically yoked to expressions of individual and group identity, as well as ostentatious displays of authority and power. Mortuary monuments commemorating deceased leaders thus represent ideal venues to examine potential differences in how social memory was produced in funerary ritual. Here I will discuss how social memory was inscribed in mortuary practice during the Late Bronze-Early Iron Age (ca.1200-200 B.C.) in Mongolia, and subsequent changes associated with the formation of the first nomadic polity in Inner Asia, known as the Xiongnu (ca. 200 B.C.-200 A.D.). I adopt a scalar perspective that emphasizes that monuments produce social memory at different temporal scales simultaneously, which offers insight into how they were envisioned, experienced, and used by those who produced them. By adopting a scalar approach to social memory, I will demonstrate that in comparison to preceding periods, Xiongnu mortuary ideology restricted the capacity to produce commemorative narratives in the longue durée. Whereas previous monument types represent grand architectural narratives relying on flexible funerary ideologies to produce idiosyncratic narratives, Xiongnu monuments are inconspicuous, standardized, and only produce social memory on a small scale.

Johansson, Lindsay (University of Colorado, Boulder)  
[262]  Faunal Perspectives on the Promontory

Following excavations in the Promontory Caves and at several open sites in the Provo River Delta region,
Steward (1937) characterized the Promontory culture as large game hunters. He based this on the high number of bison bones recovered within the caves. Excavations at additional Promontory sites along the Wasatch Front contain faunal assemblages which differ significantly from those in the caves, showing that people living at open sites relied more heavily on small game, waterfowl, and aquatic resources than large game. These differences have been mostly attributed to Steward’s sampling strategy and lack of screening, but faunal material recovered during 2011 excavations at the caves support Steward’s initial assessment: the people living in the caves were hunting large game and little else. Using faunal data from seven sites, I discuss how the faunal assemblages differ and the implications of hunting practices in discussions of Promontory culture.

Johnson, James (University of Pittsburgh)
[20] Disassembling Community and Complexity in the Eurasian Bronze Age: Social Transformations during the Middle through Final Bronze Ages, Southern Urals, Russian Federation
The Middle Bronze Age, in particular the Sintashta period (2100–1750 cal. B.C.), has often been portrayed as the apex of social complexity with the appearance of twenty-two fortified settlements in the southern Urals. In addition, this period is seen as foundation for later cultural developments but with receding tendencies towards complexity. This paper, based on my dissertation research, retroactively explores the emergence of the Sintashta phenomenon and its relation to later developments in the LBA and FBA. The roles of demographic dispersion, changes in visibility and territory, and differentiation in techniques of pottery production are used to highlight the importance of social memory and technical practices in the establishment of new social and political communities in the region and beyond. This paper suggests that current models of complexity may be inadequate to address the social and political changes noted in Bronze Age societies. I focus on the development of and changes to communities at the local and micro-regional scale to evaluate changes “on the ground”, rather than speculate on changes noted at the meta- or grand narrative level.

Johnson, Jay (University of Mississippi) and Bryan Haley (Tulane University)
While elevation and soil type have long been recognized as strong predictors of site location in the Yazoo Basin of northwestern Mississippi, little attention has been paid to the impact of annual flooding on the subsistence strategies and social segmentation of late prehistoric populations in the region. Ethnography, historic accounts, ceramic phase distributions, and computer simulations of flooding events will be used in this first assessment.

[41] Mobility and Settlement before the Lakes and Marshes: Sediment Deposition in the Closed Basins of the Yalburt Yaylasi Archaeological Landscape Research Project
Beginning in the late Ottoman period, new communities settled in the area the Yalburt Project and canals were constructed to drain the waterlogged landscapes of the Çavuşçuğol Basin and the nested Ilgın Plain, Bolasan Valley, and Atlanti Plain. In these two closed basins on the western border of the Anatolian Plateau, sediment deposition in the plains and valley floors had turned cultivable areas into lakes and marshes. In 2013 the Yalburt Project concentrated on the drained Kurugol seasonal lake. The profiles of numerous wells with wedged-shaped trenches facilitated the study of sedimentation in the lake area and the finding of the edges of a Hittite mound and Roman land surfaces under the 30 cm deep sediments of the drained lake dated by the project to the medieval and modern periods. The road from the southwest wound by the Hittite settlement at Uzun Pınar and cemetery of Çalli Ağil before crossing this plain to the Hittite settlement of Misafirli. After retreat in the Iron Age, this landscape of mobility and settlement starts again in the early Hellenistic period with hollow ways marking the reuse of Hittite roads and forming a northern branch of the common road from Ephesos to the east.

[59] Figures of Moche Past: Examining Identity and Gender in Domestic Artifacts
Artistic themes and cultural icons depicted on domestic artifacts are reflective of larger social and cultural ideologies, especially those related to gender roles and identity. Although representations of women are rare in Moche elite-sponsored art, they are abundant in household artifacts throughout all time periods.
Additionally, female figurines were one of the main avenues for artistic expression of feminine identity in Moche art. Male figures, on the other hand, are found in the form of decorative whistles and reflect a distinct masculine identity embedded in warrior-related themes. Excavations at Pampa Grande and the Pyramids of Moche have revealed that figurative artifacts were produced in middle-class households, outside the realm of state-sponsored production. They were distributed locally and addressed the needs and desires of the average Moche citizen. Whistles allowed non-elites to actively take part in ceremonies thus fostering a sense of inclusive identity for participants, while figurines allowed women to engage in activities and rituals pertinent to their primary concerns not addressed in the more prominent ceremonies carried out at the temples.

The Making of "6 Generations": A Collaborative Filmmaking Experience

Archaeologists who wish to produce video documentaries that appeal to a broad audience have much to learn from professionals in the film industry. One of the challenges in converting a script to film is to engage the audience immediately during the film’s introduction. "6 Generations" is a documentary film sponsored by the Santa Barbara Museum of Natural History, which won a special award for “Increasing the Awareness of the Ethnographic Record” and was first runner-up for Best Film at The Archaeology Channel's 2013 International Film and Video Festival. In “6 Generations,” Ernestine Ygnacio-De Soto, who collaborated on the script, narrates the history of her Barbareño Chumash family beginning with the Spanish colonial era and continuing down to the present day. Family oral tradition, twentieth ethnographic interviews, and mission records provided the source material, but it took an experienced cinematographer working with a film editor to craft a compelling opening. A comparison between the first attempt at an introduction and the final version illustrates what is needed to draw in the viewer.

All Hail the Ajaw? Shifting Political Strategies between Late Formative and Classic Period Sites in the Cucuyagua and Sensenti Valleys of Western Honduras

The transition between the Late Formative and the Classic period was tumultuous in Copan's Periphery. Late Formative monumental centers in the El Paraiso, La Florida, Sensenti and Cucuyagua valleys were abandoned. Shifts in material culture in these valleys reflect an increasing stylistic influence from the Lowland Maya. Shifts in political organization also occurred. However, the lowland Maya model of centralized power wielded by ruling local lineages was not uniformly adopted. Rather, in some regions political fragmentation and decentralization also occurred. This paper will explore shifts in political organization in Copan's periphery. It will draw on data collected during three seasons of survey in the Cucuyagua and Sensenti valleys, two extensive valleys south of Copan and will explore changes in settlement pattern, site nucleation and monumentality between Late Formative and Classic period sites in both valleys. Data from the Cucuyagua valley indicate an increase in centralization from the Late Formative to the Classic period. However, data from the Sensenti valley suggest greater centralization during the Late Formative period, and fragmentation during the Classic period. Ultimately, these data suggest a greater heterogeneity than previously thought in political forms within Copan's periphery.

Emal, Yucatan: Recent Investigation of this Center of Ancient Maya Salt Production

The modest site of Emal, Yucatan appears to have been one of the largest centers of ancient Maya salt production. Recent field research has focused on understanding the production and export of this salt, as well as local subsistence strategies and the long-distance trade passing through this site. This report draws data from our recent mapping, surface collecting, and soil sampling to begin to answer questions related to these three research topics. It outlines the method, evidence, and logistics of salt production at Emal, and discusses the methods we are using to understand the production of one of Yucatan's most important exports, as well as the problems we have encountered trying to trace a commodity with almost no archaeological correlates. The report concludes with a look forward to the research questions the project will be tackling in the coming field seasons.
Johnson, Phillip (Texas A&M University)

[242] Organization of Basalt Adze Production at the Lau'agae Quarry Complex on Tutuila, American Samoa

Archaeological research in Samoa and throughout Polynesia has provided evidence for prodigious and potentially specialized basalt adze production on the island of Tutuila, American Samoa. Although there are a multitude of recorded basalt quarries across the island, research on adze production has primarily focused on the western region of the island, and the potential for specialized adze production intended for off-island export. This paper presents the investigation of production, distribution, and consumption of basalt adzes from the Lau’agae basalt quarry complex (AS-21-100) located in far eastern Tutuila. Technological analyses of debitage, blanks, and preforms collected from two production locales at AS-21-100 were used to investigate the organization and potential standardization of production at the site. Elemental concentration data derived from EDXRF analysis of basalt artifacts was employed to explore the distribution and consumption of basalt adzes produced at AS-21-100. These data were compared to similar data from other Polynesian basalt adze manufacture sites and evaluated against multiple models of economic specialization to understand the organization of and impetus for adze production in this region of Tutuila.

[291] Kinship and Heterogeneity of Frailty: A Case Study from Spanish Florida

Bioarchaeologists have spent considerable effort identifying kin in archaeological sites and generating methods for doing so. Questioning why it is important to do so has been given less emphasis in the literature. In this paper we present data on a kinship analysis from a mission period site in Spanish colonial Florida. Multivariate methods are used to identify kin groups within the church, ground-truthed with archaeological data, and then compared with patterns of stress and health indicators within the site. These analyses demonstrate the presence of family groups within the church cemetery, that some families experienced higher mortality than others during the period in which the church was used for interment, and those families that suffered higher mortality rates also exhibited significantly higher rates of stress, thus reflecting heterogeneity and heritability of frailty within an archaeological sample. Using these data we argue that the identification of kin groups in archaeological sites should be the first step toward a “bioarchaeology of community” that addresses issues of relevance to contemporary society: inter-generational inequality, intra-community economic and political dynamics, and the role of family in determining the life course of individuals.

[23] Picks, Shovels, and Computers: Data Mining the Alpine Archaeological Record of the Colorado Rocky Mountains, USA

The prehistoric record of the Colorado alpine ecosystem is well known in regards to Altithermal refugia and communal hunting, among other topics. Much of this knowledge is due to the efforts of the late Jim Benedict, with his work based in the Indian Peaks and Rocky Mountain National Park, the mountainous regions west of Boulder. However, the Southern Rocky Mountains contain other ranges, ecologically distinct from that of the Colorado Front Range. As part of an ongoing baseline investigation, this project summarizes over 2,200 prehistoric and 5,000 historic archaeological sites located above 3000 m in Colorado. Classifying the Colorado mountains into 26 zones, we statistically analyze the abundance and types of sites to identify land use patterns related to prehistoric subsistence and mobility, in addition to gaps in the present data. Rather than demonstrating a normative “mountain adaptation”, ancient peoples exhibited diversity in their use of Colorado ranges.

Johnston, Philip (Harvard University)

[332] Production Practices and Colonial Societies: Phoenician and Indigenous Potters at Castillo de Doña Blanca (Spain)

In this talk I will argue that producers constitute a crucial demographic for the study of social change in colonial settings, with a focus on my examination pottery production at the Phoenician colony of El Castillo de Doña Blanca (Spain) using petrography, NAA, and pXRF. Over the past two decades, comparative archaeological research on pre- and proto-historic colonies has placed heavy emphasis on mundane and conspicuous consumption practices, and on the way consumption patterns reflect processes of social renewal and genesis in colonial settings. This focus on consumption has left the
social consequences of another important colonial economic sphere – production – relatively unexplored. Drawing from a rich tradition of comparative archaeological research on specialized production and technology, and from ethnographic studies of production activities in traditional societies, archaeologists today are in a position to precisely reconstruct the social and material contexts of many ancient production activities. In the study of colonial settings, such reconstructions can provide a basis for identifying and describing producer communities, for describing the social boundaries and technology exchange, and for investigating the consequences of the colonial setting on their activities.

Jolie, Edward (Mercyhurst University)

[202] Matting Matters in Chaco Canyon, the American Southwest, and Mesoamerica

Due in large part to its perishability, woven matting has long been a neglected artifact type in Southwestern archaeology. Early archaeologists noted it, but few collected anything but the largest or best preserved fragments. Matting assemblages of significant size were unavailable until excavations at sites such as Pueblo Bonito and Aztec Ruins produced dozens of examples, but these remained unstudied for decades. Although ubiquitous in mortuary contexts, poor preservation and a perception that matting reveals little about ancient peoples except that they worked, slept, and were buried on mats has only contributed to their neglect. This presentation revisits the subject of woven matting and its importance to pre-Hispanic peoples of the Colorado Plateau during the Pueblo era by drawing on insights obtained from the reanalysis of matting from Pueblo Bonito and Aztec Ruins. Consideration of technological stylistic variation in conjunction with evidence for matting’s likely symbolic content suggests that matting had heretofore underappreciated significance in Chaco Canyon and beyond, with further implications for our understanding of certain ceramic decorative motifs and the influence of Mesoamerican belief systems.

Jolie, Edward A. [336] see Urana, Lauren

Jones, Travis, Daniel Bigman (Georgia State University) and Jeff Speakman (The University of Georgia)

One of the most popular applications of near-surface geophysical survey in archaeology is the identification of unmarked burials and the delimitation of cemetery boundaries. Traditionally, archaeologists have utilized ground-penetrating radar, electromagnetic induction, resistivity, and, in some cases, magnetometry to survey sensitive historic remains located in cemeteries. Despite the success of these techniques, the archaeological community should continue to develop additional non-invasive strategies for the identification of unmarked graves. This poster presents the results of an experimental study at the Prior Family Cemetery located in Morgan County Georgia. We compare field magnetic susceptibility measurements, lab magnetic susceptibility measurements, and total phosphate counts from a variety of different locations including known burials, suspected burials identified by ground-penetrating radar, and non-burial areas. Our study indicates that field and lab susceptibility can distinguish between burials and non-burials in this soil context and are useful supplements to traditional geophysical techniques. However, the utility of total phosphate in measuring variation between burials and non-burials is limited.

Jones, Olivia (Groningen Institute of Archaeology, University of Groningen, The Netherlands)

[28] Piles of Bones: Materiality as an Aid to Assess Meaning from Commingled Confusion

Commingled human remains are found in diverse combinations and contexts; how can researchers analyze and understand these assemblages? In this paper, the specific question is: how can bioarchaeologists interpret a large enclosed tomb, in which disarticulated and commingled human remains are placed in piles? The case study derives from a Late Bronze Age, approximately 1550 B.C., stone tomb (Petroto, in southern Greece) in which one level of the tomb floor consists of piles of human remains placed near the eastern edge of the tomb. Are these piles the result of purposeful human action? Why are the dead placed in this way? The context and human remains are examined to determine the actions involved in the secondary burial(s). The case study is placed in its wider context: norms and variation of secondary treatment in Mycenaean tradition. Lastly, by viewing “the body as artifact” and utilizing materiality theory, researchers can interpret the piles of human remains as indicative of complex ideology, symbolic use of the dead and the lived experiences of tomb reuse. The social theory of materiality can be an important tool for interpreting bone commingling and placement as culturally
meaningful and purposeful in the lives of the Mycenaean people.

Jones, Eric (Wake Forest University)
[34] Multiscalar Settlement Ecology Study of Late Pre-Contact Piedmont Village Tradition Communities in North Carolina
This research uses regional and local survey data and site-level excavation results to explore the settlement location choices for Piedmont Village Tradition (PVT) communities and households from A.D. 1200 to 1600. Analysis of regional settlement patterns in the North Carolina Piedmont with reconstructed past landscapes provides a general baseline for determining what factors were influencing PVT community decisions of where to live. An analysis of settlements in the upper Yadkin River Valley (UYRV), allows for the exploration of local variability within the regional patterns as well as community-specific variability with regard to settlement size and sociopolitical organization. Discovery of a potential structure at the 31YD173 site also allows us to examine location choices at the household scale. The results of these recent investigations enable an explanation of PVT settlement location choice, they shed light on what those findings tell us about cultural patterning and development, and they demonstrate the benefits of multiscalar settlement ecology research.

Jones, Bradford (Texas Historical Commission)
[95] The Aranama and the Art of War: Local Knowledge, Colonial Practice, and Lithic Technology in Late Prehistoric and Spanish Colonial South Texas
The establishment by the Spanish colonial government of a presidio and mission along the lower Guadalupe River in the south coastal plain of Texas in the 1720s redefined the daily lives and material traditions of local Aranama groups. From an archaeological perspective, this includes the not unexpected decline in the diversity and use of lithic tool assemblages compared to preceding periods. However the manufacture of lithic projectile points likely persisted at least until the secularization of the Texas missions in early 19th century, but with an early and distinct stylistic shift to the use of what regionally are referred to as Guerrero points. This paper focuses on historically contextualizing Aranama projectile point use in order to explore how local lithic technologies and projectile point styles were re-imagined by the convergence of local and Spanish colonial knowledge and practices, particularly warfare.

[103] Stable Carbon and Nitrogen Isotope Analysis from La Playa, Sonora, Mexico
The La Playa site (SON F:10:3) represents a massive Early Agricultural period (1600 B.C.-A.D. 200) settlement in northern Sonora that includes a large mortuary component and evidence of substantial early reliance on agriculture, including irrigation features. Bone samples from 14 individuals from the osteological collections at the Centro Instituto Nacional de Antropolig1a (INAH) in Hermosillo were processed at the Center for Archaeological Research, University of Texas at San Antonio for 13C and 15N collagen and 13C apatite stable isotopes. The sample is representative of the San Pedro phase (1200 B.C.-800 B.C.), the Cienga phase (800 B.C. - A.D. 150), and the Ceramic period (A.D. 200-A.D. 800). The results indicate that 13C and 15N values are consistently elevated throughout the sequence. Substantial use of C4 and CAM plants, including wild resources and maize, is inferred. The potential sources of the elevated 15N values are discussed.

Jones, Terrah (UCLA Cotsen Institute of Archaeology), Benjamin Nigra (UCLA Cotsen Institute of Archaeology) and Jacob Bongers (UCLA Cotsen Institute of Archaeology)
[105] Paints, Dyes, and Ochers: Red Pigment Analysis from Late Chincha Valley Mortuary Contexts
Tombs, bones, and paint, three things that when combined often indicate deliberate mortuary practices that can be associated with many different cultural groups. During a small scale intensive survey of the Chincha Valley, Peru, a team of UCLA and San Marcos archaeologists stumbled upon a series of these signs. Within this survey, that included the identification of over 70 sites, researchers observed at almost every mortuary site the application of red pigment to human skeletal remains. The repeated occurrences of this phenomenon within mortuary contexts is not unusual, however, the abundance of cases for this
particular practice within the mid-section of the Chincha Valley is staggering. As a result, UCLA researchers seek to both identify the composition of the red pigment through XRD and Raman analysis and to ascertain the significance of this pigment application in the broader mortuary practices of the Chincha Valley.

Jones, Ian (University of California – San Diego)  
[127] Outdoor Miners: The Last Day of Work at a Medieval Copper Producing Village in Southern Jordan  
In the late 12th century A.D., a small settlement dedicated to copper production was founded in the copper-rich Faynan district of southern Jordan. This site, now known as Khirbat Nuqayb al-Asaymir (KNA), was the center of the latest copper industry in the region. In order to better understand this relatively modest episode of copper production, the UC San Diego Edom Lowlands Regional Archaeology Project conducted excavations at the site in 2011 and 2012. These have provided significant insight into the daily lives and work of the site’s occupants. During the 2011 excavation season, our team uncovered a copper-smelting workshop, evidently still in use at the time of its abandonment. Piles of charcoal, ready to be charged into a well-preserved furnace, and lumps of partially processed copper waiting to be refined hint at the work left unfinished. They also provide a unique opportunity to reconstruct specifically how copper was produced at KNA. This paper uses data from this workshop, as well as several late 12th-early 13th century A.D. domestic contexts excavated during the 2012 field season, to present a snapshot of the daily life of copper miners and smelters in medieval Jordan, which until now was not well-understood.

[149] Human-Environment Interactions through the Epipaleolithic of Eastern Jordan  
The multidisciplinary approach of the Epipaleolithic Foragers in Azraq Project has given humans and the (ir) environment equal importance in reconstructing the prehistoric landscapes of, what is today, the desert of eastern Jordan. Working at three separate locations, we have attempted to integrate archaeological sites directly into the local offsite stratigraphy and, therefore, the evidence of the environment in which the sites exist today and existed in the past. The wider Levant has seen much interest in the Epipaleolithic and the correlation of societal change with large-scale patterns of post glacial climate transitions. With increased data availability, "big picture" hypotheses become increasingly questionable. To avoid their continued entrenchment, we advocate a local, bottom up approach to theory and practice. Based on observing the pressing environmental issues in the region today, we assess the human-environment relationships of the Epipaleolithic in terms of resource sustainability. Resources, cultural as well as physical in nature, vary based on supply and demand, allowing or restricting human habitation patterns. In this regard, periods of resource and human population stasis are as important as periods of change in understanding past human relationships with the environment.

Jones, Geoffrey (Archaeo-Physics, LLC)  
[196] Data Sampling Strategies in Geophysical Survey of Historic Cemeteries  
Geophysical mapping is an important tool for study and preservation of cemeteries, but human burials can be very challenging targets for detection. Historic cemeteries in the in the Euro-American tradition share commonalities of patterning that must be considered in geophysical survey design. Data sampling strategies that consider the scale, composition, and patterning of cemetery features and their environment will provide optimal resolution. Consideration of research objectives and funding also informs sampling strategy, and cost-efficiency is achieved by balancing these needs and limitations. The different types of instrumentation that might be used differ in their resolution, response, and rates of survey. GPR, electrical resistance, magnetometry, and Lidar are considered, each with its unique implications for sampling strategy.

Jones, Emily Lena (University of New Mexico)  
[286] Coming to Terms with Imperfection: Comparative Zooarchaeology in Early Historic New Mexico  
Many questions to which zooarchaeology is applied are regional in scale; for instance, was there
resource depression in artiodactyl populations, or can we see evidence of climate impacts on these same populations? While single-site analyses can provide insight into such questions, evidence from a suite of sites across the region of interest will allow a stronger argument. But comparing data from different archaeological contexts is notoriously difficult: differences in site function, site formation, excavation history, and (in some cases) data recording can make comparative studies a challenge. In this paper, I use examples from an ongoing comparative project in early historic New Mexico to illustrate both the problems and the potential of comparative zooarchaeology.

[7]  The Emerging Archaeology of Ford Dry Lake: Recent Results from California’s Chuckwalla Valley  
Ford Dry Lake, located in California’s eastern Colorado Desert, is part of a system of ephemeral Holocene playa lakes that supported prehistoric peoples across the southwestern United States. Periodically infilling to support habitats that sustained natural resources suitable for human exploitation, these playas were connected by networks of trails that carried goods and people from the interior deserts and Colorado River to the California coast. While broad swaths of the desert were examined by Malcolm Rogers in the early 20th century, recent archaeological research at Ford Dry Lake is bringing new data to light in an area that has not been comprehensively studied in the past. Pedestrian surveys, controlled grading, geoarchaeological trenching, and artifact analysis are yielding important information about the geomorphological history of the area and the human use of this locale in the prehistoric era. LIDAR, soil analysis, patterns of flaked and ground stone deposition, and ethnographic research combine to illustrate the use history of this local environment and provide comparative data for other playa geographies. This continuing work will develop a landscape-level picture of the Ford Dry Lake area which can be integrated into a more refined region-wide understanding of prehistoric land use in the southwest.

[138]  Ceramic Petrographic Analyses at Uxbenka, Belize  
Uxbenká, an Early Classic to Late Classic period Maya polity, is the most extensively excavated site in southern Belize. Recent ceramic analyses have succeeded in refining our understanding of the extent and duration of occupation at Uxbenka (through the creation of a ceramic chronology based on attributes of style and form) as well as its position in regional interaction spheres. The chronological data is corroborated by an independent, high-precision AMS radiocarbon chronology. To date, little effort has focused on paste variation and attributes of ceramic technology. Macroscopic analyses suggest a technological shift around the 5th century A.D. This poster presents results of petrographic analyses on a sample of 20 ceramic rim sherds derived from stratified, site core contexts. The goal of these analyses is to explore macroscopic technological variability using microscopic techniques and to determine the extent of technological change between the Early Classic and Late Classic Periods.

[246]  From Black Point to Fraser Point: Fishing and Coastal Sedentism on Western Santa Cruz Island  
Why did sociopolitical complexity develop among hunter-gatherers? Intensive agriculture, with its ability to generate food surpluses, is one of the pathways to such complexity. Among California coastal communities, however, other factors were at work. On the California Channel Islands, sedentism—often perceived as a unidirectional process of responding to shifting environmental and demographic circumstances—is strongly correlated with intensive fishing and social ranking. Whereas Middle Holocene fishing strategies are more diversified in the use of nearshore environments; Late Holocene procurement is characterized by intensified strategies and expansion into offshore, pelagic environments, facilitated by the introduction of shell fishhooks and plank canoes. Archaeological data from western and eastern Santa Cruz Island provide insights into intra-island settlement and subsistence variability. Despite the
abundance of chert and other lucrative resources on the eastern end, a comparatively higher density of substantial midden deposits occurs on western Santa Cruz Island. This difference may stem from environmental factors such as dependable freshwater, kelp forest fishing grounds, and shorelines providing access to boat launches. Documenting regional settlement variability serves as the basis for developing an interpretive framework that will contribute to understanding sedentism, intensive fishing, and hunter-gatherer complexity more holistically in coastal settings.

Joyce, Arthur [8] see Brzezinski, Jeffrey

Joyce, Rosemary (University California Berkeley)

Honduran archaeology has been shaped since the late nineteenth century by a number of broad agendas, all of them converging to ask questions concerned with how and why most societies in Honduras remained less advanced, complex, or stratified than their immediate western neighbors, including the Maya of Copan. One outcome of these views of the significance of Honduran archaeology has been a less sustained attention to how Honduran societies related to those of neighbors to the east and south, in lower Central America. In this presentation I build on my recent arguments concerning how to think about Central America as an object of archaeological investigation, exploring what taking Central America as the focus does for understanding prehispanic Honduras. Relatively restrained inequality; patronage of craft skills; the significance of spirituality as an integrating force; and a greater importance of social relations, including marriage alliance, than of political relations, especially those that are hierarchical, allow for a more comprehensive discussion of societies across prehispanic Honduras— from Copan to Nicaragua. A corollary of this argument is that the units of analysis appropriate to understanding prehispanic Hondurans will be multiple, overlapping, and will exist at multiple scales, best captured by modeling as networks.

Joyce, Arthur (University of Colorado at Boulder)

This paper takes a comparative perspective to consider the emergence of urbanism in later Formative Oaxaca (500 B.C.-A.D. 250). At this time throughout many regions of Oaxaca the archaeological record indicates population aggregation at sites including Monte Albán, Rio Viejo, Yucuita, Huamelulpan, Cerro Jazmin, Monte Negro, and Cerro de la Minas among many others. The size of these communities came to dwarf earlier settlements. These urban centers also exhibit evidence for an increase in the scale of public, ceremonial architecture and spaces that were the locus of communal rituals and political administration. Despite these similarities, Late/Terminal Formative centers exhibit considerable variability in aspects of their layout and organization, expressions of inequality and political hierarchy, and evidence for the nature of interaction both with people of outlying settlements and those in more distant regions. The history of these urban centers also varies. Most were relatively short-lived and were de-populated after only a few hundred years. Monte Albán, however, continued as a demographic, political, ceremonial, and economic center until the end of the Classic period. This paper describes the diversity of later Formative urban centers in Oaxaca and considers the ways in which they can be considered to have been urban formations.

Juengst, Sara (UNC-Chapel Hill)

The Formative Period (1500 B.C.-A.D. 200) in the Titicaca Basin was a time of important social and economic changes, such as the establishment of sedentary settlements and long distance trade routes, increasing horticultural investment, and an emerging regional ritual tradition. While archaeologists have described these changes, there has been little success disentangling the impacts of these changes on local populations. How did increased regional integration affect local communities and their relationships to each other? What impact did the Yaya-Mama Religious Tradition have on Formative Period communities? Who were the people buried at temples and what was their relationship to others in the lake basin? Were they local, autonomous individuals or drawn from different populations? This paper will report preliminary findings from several sites around the Copacabana peninsula, using health, diet, and biodistance analyses as measures of community relationships and interactions. By combining these multiple lines of evidence, we can reconstruct the daily lives of peninsular populations and see whether different burial communities shared food, disease, habits, and genetics between themselves in life.
Alternatively, burial communities may be drawing individuals from disparate living communities, which would have significant impacts for interpretation of the increased regional integration of this period.

Archaeological and Historical Perspectives on “Urbanism” in Early Historic Southeast Asia

Early historic Southeast Asian states and chiefdoms of Southeast Asia, lying at the intersection of sea and land routes linking the expanding empires of China and northeast Asia, India, East Africa, and the Middle East from the mid-first millennium A.D., challenge many traditional assumptions about the relationship between urbanism, high regional population concentrations, centralized and hierarchical socio-political structures, the ideological /religious foundations for “cities,” and the types of political economies necessary to sustain urban centers. In early Southeast Asia, hyper-large primate centers (typically housing well over 20% of the regional population) grew as trade ports or gateways to “low-density,” ethnically diverse hinterlands only loosely integrated into polity centers. These polity centers were not generally defined in terms of fixed geographic territories, but leaders and would-be leaders relied on the shifting control of labor, resources, and alliance through political gifting, religious pageantry, slave-raiding, and militarism to maintain their often relatively ephemeral regional influence and economic ascendancy. This paper presents an overview of this pre-modern Southeast Asia form of “urbanism” using several case studies from both mainland and island Southeast Asia to illustrate how these organizational features are reflected in an archaeological record that often lacks visible site architecture and perishable technologies.

Impacto Social del sitio Tlalancaleca en el Altiplano Central durante el Clásico temprano

El sitio arqueológico de Tlalancaleca en Puebla fue uno de los centros más grandes del Altiplano Central durante el Formativo tardío y terminal, y es conocido por la presencia de cultura material heredada por Teotihuacan. Para esclarecer la dinámica de la transición de Tlalancaleca hacia Teotihuacan, es necesario enfocar las investigaciones en la continuidad y la discontinuidad cultural entre estos dos sitios. A partir de investigaciones realizadas en los años 2012 y 2013 en Tlalancaleca, donde se recuperaron tiestos de Anaranjado Delgado, suponemos que este sitio puede haber tenido cierta ocupación en el Clásico temprano. Por lo cual, nos surgen interrogantes: ¿Es posible que ambos sitios coexistieran en cierto periodo histórico? Por otra parte, con base en los datos de los materiales líticos recuperados en Tlalancaleca, cerca del 50% de la obsidiana de este sitio ha sido identificada como procedente del yacimiento de Pachuca. Se sabe que dicho yacimiento que fue controlado por el Estado teotihuacano, entonces ¿Es posible que Tlalancaleca tuviera un papel como nodo de intercambio para Teotihuacan? Los objetivos principales de nuestro proyecto en Tlalancaleca intentarán contestar dichas preguntas considerando la perspectiva de la continuidad histórica. En esta ponencia presentaremos algunos resultados preliminares de dicho proyecto.

Middle Epipaleolithic Technological Variability in the Northern Levant: New Data from the Middle Euphrates

This paper presents Epipaleolithic assemblages from two sites (Wadi Kharar 16K and 16AT’) discovered by our survey of steppic areas stretching to the south of the middle Euphrates. The surveyed area (10 km x 20 km) on the Bishri Plateau is cut by a number of wadis, along which we located more than 100 spots associated with Paleolithic artifacts on the surface of the terraces. We conducted both random and systematic surface collections at some sites with high artifact density. Site 16AT’ consists of three lithic clusters, two of which comprise Epipaleolithic artifacts with some Upper Paleolithic tools. Retouched tools from this site are dominated by microliths, particularly trapeze-rectangles, which are not associated with the microburin technique. These features are consistent with those of already known Middle Epipaleolithic assemblages from adjacent areas (e.g., Palmyra Site 50 and El-Kowm). On the other hand, microliths from Site 16K are characterized by broad scalene bladelets made through the microburin technique, as indicated by the recovery of microburins and La Mouillah point. We compare these technological characteristics with those of Layers 8-3 at Yabrud III and the Mushabian to discuss the technological variability during the Middle Epipaleolithic in the northern Levant.

Kahn, Jennifer (The College of William and Mary)
[85] Monumental Architecture, Ceremonial Nodes, and Ritual Specialists: Avenues to Social Complexity in the Society Island Chiefdoms (Central Eastern Polynesia)

In complex societies, political consolidation often went hand in hand with increased efforts by elites to consolidate other aspects of socio-economic power. One strategy is to appropriate ritual spaces, ideas, and practices. My case study from the complex Society Islands chiefdoms (Central Eastern Polynesia) focuses on the materialization of ideology at the community level, concentrating on the role of monumental temple sites. Spatio-chronological analyses of temples document the enlargement and elaboration of temple architecture through time. The role of ritual specialists, particularly priests, becomes more pronounced and is materialized on the landscape with the construction of priests’ residences and specialized houses for storing ritual paraphernalia near temple sites. In later prehistory, aggregate ritual centers constructed by competing elite lineages allowed for manipulation of the political economy and integration of community economic practices within the regional ritual calendar. Aggregate complexes served as ceremonial nodes, or centers of economic, ritual, and political activities where elites and ritual specialists engaged in both sacred and secular activities, leading to a more formalized socio-political hierarchy. Similar trends are discussed for Tonga and Hawai‘i, where the onset of large monumental ritual construction correlates with the intensification of chiefly power and authority.

Kaiser, Luke (University of North Carolina Greensboro)

[181] Renovating Architectural Theories of Minoan Fortifications

The history of Minoan socioeconomic interpretations has relied heavily on the theory of a “Pax Minoica,” developed by the father of Minoan archaeology, Sir Arthur Evans. However, more recently, there has been a trend towards interpreting some Minoan structures as enclosure walls, towers, bastions, and guard houses which adds a more militaristic aspect to the traditional interpretations of a peace-loving Minoan culture. During the Bronze Age, the eastern Mediterranean was rife with warfare. Therefore, a militarized Minoan culture lies within the scope of reason. Contrarily, to subscribe to the notion of a bellicose Minoan society in the absence of significant evidence of a standing military or participation in a land war in the Mediterranean would be to oversimplify their development into a world power in the Aegean during the 2nd millennium B.C. These two opposing theories create a dualistic model that places the Minoans into a more moderate sociopolitical pattern that avoids labeling them as either pacifists or warmongers exclusively. Additionally, this multi-faceted approach, when applied to the supposed fortifications of the Minoans, provides a much deeper interpretation of their manipulation of landscape and architecture.

Kakaliouras, Ann (Whittier College)

Recent bioarchaeological work has moved the discipline intriguingly closer to current archaeological and sociocultural theory, particularly research framing human relationships as affective, not just adaptational. Perceiving past peoples and their remains as subjects in relation to others—their contemporaries, descendant communities, and bioarchaeologists themselves—may mark the emergence of a true post-processual Bioarchaeology. The category “community,” though, has a long and troubled history within Anthropology proper, having been over-used and under-defined for much of the 20th century. A renaissance of anthropological concern for and focus on “communities” demands a thorough and critical analysis of our very particular purposes for utilizing the concept. Specifically, bioarchaeologists have a “population problem;” that is, the field’s historical orientation toward samples and populations, itself an artifact of New Physical Anthropology’s jettison of individualistic approaches, represents both a tension and a pivot point for exploring other theoretical frameworks in the field. Further, relationships between bioarchaeologists and descendant communities remain complex and sometimes fraught with suspicion that researchers objectify past people by defining them as populations. In this paper, then, using disciplinary histories, archival research, and current sociocultural theory, I sketch a theoretical, contextual, and ethical map for efforts toward a “Bioarchaeology of Community.”

Kamnikar, Kelly (Mississippi State University), Amber Plemons (Mississippi State University), Nicholas Herrmann (Mississippi State University), Derek Anderson (Mississippi State University) and Molly Zuckerman (Mississippi State University)

Many technological methods from fields such as odontology, toxicology, pathology and biology have been used in forensic sciences for analysis of material and biological evidence. However, these methods have not been uniformly applied in bioarchaeological or forensic anthropological contexts. In this presentation, we show the importance of applying methods rooted in forensic sciences, like Scanning
Electron Microscopy (SEM), Energy Dispersive Spectrometry (EDS) and isotopic techniques, when analyzing historic burials in the Southeast and interpreting their results. We compare osteological data from three cast iron coffins and caskets dating to the mid-19th century in Mississippi to understand life histories. Two burials are from the small rural Gale Family Cemetery near Jackson, Mississippi and the third is a single cast iron coffin burial from Monroe County, Mississippi. We demonstrate the utility of transition analysis (TA) aging, a method developed in bioarchaeology and refined by recent forensic anthropology research. TA is beneficial when sample size is limited as it provides an unbiased age range based on multiple criteria. By combining methods from both subfields, as well as those developed in other areas of forensic science, information generated from the limited sample size may supplement our understanding of the individuals in their historical context.

Archaeology of Childhood and the Concept of Personhood

Recent studies have begun to apply the concept of personhood to the archaeological record as part of the continuing attempt to examine socially constructed roles. Research on children at Amache, a WWII Japanese Internment Camp, is used to explore how the concept of personhood can enrich the archaeology of children by eliminating a broadly-defined focus on “children” or “childhood”. This paper will examine whether it is possible to identify the impact of gender, age, and other social and economic variables on the archaeological record to interpret the varying activities and social roles of children.

A Non-equilibrium Framework for Analyzing Cultural Change

Neutral evolution is a frequently used model to analyze changes in frequencies of cultural variants over time. Here we present a non-equilibrium neutral model which accounts for temporally varying population sizes and mutation rates and makes it possible to analyze the cultural system under consideration at any point in time. This framework gives an indication whether observed changes in the frequency distributions of a set of cultural variants between two time points are consistent with the random copying hypothesis. We find that the likelihood of the existence of the observed assemblage at the end of the considered time period (expressed by the probability of the observed number of cultural variants present in the population during the whole period under neutral evolution) is a powerful indicator of departures from neutrality. Further, we study the effects of frequency-dependent selection on the evolutionary trajectories and present a case study of change in the decoration of pottery in early Neolithic Central Europe. Based on the framework developed we show that neutral evolution is not an adequate description of the observed changes in frequency.

Studies of Black-gloss Pottery from Monte Pallano (Italy) I: Archaeological Setting and Macro-morphology

This is the first of a series of four papers that report multi-faceted studies of a collection of 200 sherds of black-gloss pottery (a type of fineware that was used for dining and wine consumption from the 5th century B.C.E.-1st century B.C.E.) excavated from the Monte Pallano ridge in the Abruzzo region of eastern Italy. The study region includes two distinct areas: a hilltop settlement and a nearby sanctuary precinct. Some of the ceramics were made locally; others made elsewhere. The studies apply three different methodologies: macro morphological examination (this paper), petrography (Agostini), and x-ray fluorescence (Conley). Traditionally, pottery analysis begins with classification of the sherds into fabric groups based upon macroscopic examination, i.e. creation of a fabric series. Effectively the analyst considers the physical attributes of the sherds and groups them based upon a subjective assessment of their similarities. Individual analysts may well classify the same assemblage into different groups, some using a relatively large number (“splitters”) and others using a smaller number (“lumpers”). Here the analysis begins with a quantification of physical characteristics (Munsell color, texture, compactness, hardness, inclusions, and voids) and applies multivariate statistical techniques to establish the groups used in subsequent analysis.

Kansa, Sarah (AAI / Open Context) [286] Documenting and Disseminating Zooarchaeological Data in the Digital Age

Thirty years ago, Caroline Grigson wrote what was to become a landmark essay providing guidelines for reporting animal bone analyses in archaeology (Grigson 1978). Grigson aimed to improve the quality and comparability of information scholars shared and to ensure that it was sufficient for future analyses and interpretations. She saw data presentation as “the most important part of a zooarchaeological report” and recognized that unless data is “published or archived in full, much of the value of the excavation will be lost” (Grigson 1978, 122). Although zooarchaeologists have long-recognized that full description is critically important, the limits of conventional publication have usually prevented sharing such detailed information. Lack of full disclosure of data, and of the methodological procedures used in its collection and analysis, means that vast amounts of documentation are lost between data collection and its ultimate dissemination. The Web offers new opportunities to efficiently and comprehensively document and disseminate our work, but simply archiving datasets is not enough. We discuss how the implementation of systems of formalized data publication and peer review, such as those in development with Open Context (http://opencontext.org), can create comprehensive, well-documented datasets that are more comprehensible and useful to our peers and future researchers.

Kansa, Eric (Open Context / UC Berkeley) [81] Navigating and Visualizing Archaeological Data on Vastly Different Scales

Archaeological research can focus on scales ranging from observations on individual objects to macro phenomena that span millennia and continents. Such scalar differences pose a great challenge in digital data dissemination, particularly in finding and visualizing relevant data. This poster presents common data indexing strategies to hierarchically nest time-span and geographic coordinates on very different levels of temporal and geospatial resolution. The approach presented here simplifies interface, visualization, and interoperability and will be demonstrated with Open Context (http://opencontext.org). This poster illustrates applications on micro-scale data from within individual archaeological sites as well as continental scale site-file data from the Digital Index of North American Archaeology (DINAA). DINAA aggregates site-file data from multiple State Historical Preservation Offices (SHPOs). The nested indexing strategy demonstrated here enables visualization and discovery at a level of spatial resolution that does not compromise site location security, but is useful for map visualization of multiple dimensions of data. Kansa, Eric [36] see Wells, Joshua

Kantner, John (University of North Florida) [56] Borderlands in the Chaco World: The Case of the Dutton Plateau

Archaeologists have long struggled to define the character and range of influence of Chaco Canyon, an impressive monumental site located in the San Juan Basin of the northern U.S. Southwest. Often imprecisely referred to as the “Chaco phenomenon” with some undefined form of authority across a vaguely delimited “Chaco world,” Chaco Canyon is variously seen as the seat of a powerful state, the location of a widely revered ceremonial complex, and/or the center of a cooperative economic system. This paper proposes that viewing the broad Chaco landscape as a series of shifting borderland zones with fluid ethnic, political, economic, and religious boundaries may help to explain why Chaco Canyon has proven so difficult to characterize. The paper focuses specifically on the Dutton Plateau, the topographic feature that marks the southern edge of the San Juan Basin, and explores geographical, economic, and cultural evidence demonstrating the complex and fluid nature of this borderlands area.

Kantor, Loni (Arizona State University) [200] Words and Things: Archaeological Insights from Indigenous Languages

The hypothesis of language relativity holds that languages differ in the ways they encode objective experience, and that people sort out and distinguish things and experiences in large part according to the categories provided by the language they speak. It stands to reason, therefore, that indigenous language categories for things, insofar as they differ from our own, may offer unique perspectives on the
archaeological record. In this paper I examine linguistic categories pertaining to the landscape in Wixárika (Huichol) and Náhuatl, and I assess how they may enhance our interpretations of ancient sites. The findings presented here indicate that landscape-related linguistic categories in both languages have the potential to shed further light not only on the configuration of ancient settlement systems, but their symbolism as well.

Kappelman, John [109] see Kay, Marvin

Kappelman, John (University of Texas at Austin), Lawrence Todd (University of Texas at Austin), Jim Feathers (University of Washington), Anne Skinner (Williams College) and Hong Wang (Illinois State Geological Survey) [201] Ages of Late Middle Stone Age Sites at Shinfa in the Horn of Africa

Anatomically modern Homo sapiens left Africa during the Middle Stone Age (MSA). Although the dispersal point is broadly believed to be the Horn of Africa, with a route either north within Africa (Nile River or Red Sea coast), or east across the Red Sea at the Bab el Mandeb Strait, few sites are known from this region. We report a series of late MSA sites in the Horn on the lowland slope of Ethiopia’s northwestern plateau along the upper reaches of the Shinfa River, a Blue Nile tributary. These open air sites are usually in proximity to ancient river channels. Absolute dating using optically stimulated luminescence (OSL) of feldspars, electron spin resonance (ESR) on mammal teeth, and accelerator mass spectrometry carbon dating (AMS 14C) on ostrich eggshell (OES) together show a consistent pattern of ages, with river incision producing younger terrace deposits. A series of AMS 14C dates at SM1, an excavated locality, show that this site dates from 31–46 cal ka BP, while OSL and ESR dates suggest older occupations at higher terraces. These ages permit comparisons with local and global climatic records and provide support for the idea that these late MSA populations were riverine-based foragers.

Kara, Alex (Boston University) and Lauren Santini (Harvard University) [295] A Fistful of Data: Quantitative, Exploratory Analysis of Combined Remote Sensing and Archaeological Data

Imagery captured by satellite and airborne sensors has seen such widespread use in landscape archaeology that these data are now conventional to the discipline. However, the amount and complexity of information in multivariate raster files can be overwhelming, and applying this imagery to understanding past human behavior remains a challenge. Identifying the contributions of ancient human activity, represented as GIS vector files, to remotely sensed data further complicates analysis. Classification algorithms and more customized models have been used to extract concealed patterns from raw pixel values, but such rigid methods tend to diminish human interpretation and generalize over important data. This paper presents a versatile framework for quantitative, exploratory analysis that prioritizes both the interpretation and integration of data collected by fieldwork and remote platforms. This approach implements techniques established by applications within community ecology, and a case study of the region surrounding the ancient Maya sites of San Bartolo and Xultun, located in northeastern Petén, Guatemala, demonstrates their potential.

Karasik, Avshalom (Israel Antiquities Authority) [65] The Digital Era: Archaeological Documentation and Analysis at the Israel Antiquities Authority

As the largest archaeological organization that oversees around 300 excavations per year, the Israel Antiquities Authority visualizes the near future as the turning point from old traditional documentation methods into the digital era. The remarkable advantages of new technologies are self-evident and have been presented several times in the past. However, the huge amount of data accumulated annually at the IAA calls for a systematic and complete solution that goes beyond the feasibility test of scanning archaeological artifacts in 3D. The presentation will report on the innovative activity of a new lab – ‘The National Laboratory for Digital Documentation of Archaeological Artifacts’ – that was initiated last year by the Israel antiquities authority. The lab is running in parallel and with close connections with the ‘Computerized Archaeology Laboratory’ at the Hebrew University of Jerusalem. The mutual purpose of the twin laboratories is to harness mathematical and computational methods to support archaeological research, documentation, and visualization. The laboratory is equipped with modern, high precision scanners which provide digital models of archaeological finds. We apply and continue to develop several tools and algorithms which are used routinely as the ultimate procedure for the analysis, publication and digital storage of the finds.

The Lucas Gusher Spindletop Oil Field National Historic Landmark Archaeological Investigations of the Golden Triangle Storage Project 90-Acre Central Storage Site, Beaumont, Jefferson County, Texas

There are several unique aspects to the archaeological investigations of the Golden Triangle Storage (GTS) Project 90-acre Central Storage Site on the Spindletop Oil Field National Historic Landmark (NHL, nominated 1979), Beaumont, Jefferson County, Texas. Resulting from the explosion of oil spewing from the Lucas Gusher on Spindletop Hill in January 1901, many of the world’s leading oil companies got their start in the energy business and forever shaped the future of world energy production. Since 2008, William Self Associates, Inc. (WSA), on behalf of GTS, has conducted historic research and 21 separate archaeological field investigations including three mitigation projects. WSA identified 11 Archaeological Sensitivity Zones (ASZ’s) on the Spindletop Oil Field consisting of industrial and residential archaeological remains, and eight standing historic-age wooden tanks. The project included an extensive public involvement phase with local television media, the Boy Scouts of America and the Jefferson County Historical Commission. Project awards include the 2011 Texas Historical Commission (THC) Award of Merit in Archaeology, the 2012 Council of Texas Archaeologists (CTA) E. Mott Davis Award for Excellence in Public Outreach, and nomination of the project in 2013 as a Section 106 Success Story by the Advisory Council on Historic Preservation.

Prehistoric Earthworks in Wayne County, Ohio

Ohio is home to an impressive number of major earthworks that include burial mounds, geometric structures, and enclosures. Among the key sites known to all students of prehistory are Serpent Mound, Adena Mound, the Newark Group, the Chillicothe Group (Mound City), and Ft. Ancient. The majority of the sites, and much of the archaeological interest, are concentrated in the southern half of the state, the heartland of the Adena and Hopewell cultures of the Early and Middle Woodland periods (1000 B.C.-AD 500). However, a significant number of the more than 4000 earthworks are found in other parts of Ohio. An examination of the earthworks found in Wayne County (located in the northeastern part of the state) and their artifacts is useful for understanding regional efforts at mound construction outside the core area. This presentation discusses the variety of features, their common elements, their distribution in the county, and the types of artifacts they contain. Many of the earthworks probably served as ceremonial markers and gathering places in a landscape thinly populated by people.

Kari, James (Alaska Native Language Center) and Ben Potter (University of Alaska Fairbanks, Department of Anthropology)

The Prehistoric Implications of The Proto-Dene Lex Loci

Dene is largest language family in area of Native North America. The model that Kari refers to as the Proto-Dene Lex Loci (‘words of location’) is based upon linguistic and ethnogeographic data from 11 contiguous Alaska Dene languages that support long-term continuous and largely exclusive Dene occupation of most of Central Alaska. Watershed tenure and place name planning by early Dene bands can be detected by an array of ethnogeographic devices. Dene place names are astoundingly analyzable and hence constantly informative. These include a rule-driven sign+generic generative geography capacity; shared multilingual place names; and occasional founding place names, boundary-marking place names, or patterned duplications in place names. Proto-Dene geographic navigation is framed in a nine-point polyhedral riverine directional system. Potter comments that archaeological patterning between middle Holocene (Northern Archaic tradition) and late Holocene (Dene/Athabaskan tradition) suggests continuity among Subarctic Alaskan material cultural patterns as well as significant change around 1000 cal BP. In the context of Edward Vajda’s (2010) Dene-Yeniseian historical linguistic hypothesis, Na-Dene presence in North America at 12000 BP invites scrutiny.

[260] Food and Feast: Analysis of Plant and Animal Remains from Feltus

This paper presents the results of faunal and botanical analyses of feasting deposits at Feltus, a well-preserved Coles Creek (A.D. 700 – 1200) site in Jefferson County, Mississippi. Though it once consisted of four mounds surrounding an open plaza, excavations have shown that the most intense activity at Feltus took place before the mounds were constructed. During this early period, and extending into the period of mound construction, the site hosted ritual gatherings focused on feasting. Here, I explore the nature of that feasting through the plant and animals that were consumed. However, abundant bear remains in the deposits signify the importance of looking beyond the dietary value of certain species. Bears have been potent ritual symbols since people first entered North America, and their meaning has stayed remarkably constant—bears are food providers, they are kin to humans in a different way than other animals, and they have the ability to communicate and navigate between the human and spirit worlds. Their abundance, combined with the otherwise everyday nature of the food remains at Feltus, suggests that these events were communal in nature and functioned to stimulate group cohesion and a sense of identity and equality with participating community members.

[164] The Chicahuaztli: The Power of a Precolumbian Rattle Staff

Music is an important cultural element found throughout Mesoamerica. By studying particular instruments, we can begin to understand the role an instrument played within a society, and can then use our understanding of that instrument to further our analysis of the various iconographic scenes in which the instrument appears. I will focus on one of the instruments found in ancient Mesoamerica, the chicahuaztli. The chicahuaztli is a type of rattle staff that could only be used in elite religious ceremonies. This paper will focus on depictions of the chicahuaztli found in various precolumbian codices including the Codex Borgia, the Vaticanus B, the Fejérváry- Mayer, the Dresden, and the Madrid. By exploring the various aspects of the chicahuaztli I hope to achieve several goals: first, I intend to highlight the significance this musical instrument held in precolumbian Mesoamerican societies; second, I will explain
the role this instrument played and the deities associated with it; and third, I will demonstrate how the presence of the chicahuaztli can facilitate the understanding of several iconographic scenes within the codices. The chicahuaztli became more than just an instrument, it became an iconographic element.

Katz, Gregory
[211] Quartz Procurement and Reduction in the Potomac Fall Zone: A View from Langley, Virginia
The Louis Berger Group, Inc. recently conducted an archaeological survey and evaluation of Langley Fork Park in Fairfax County, Virginia. Two prehistoric quartz quarry workshops (44FX3635 and 44FX3637) were identified in the survey and were subjected to intensive research and excavation. Analysis of site data and curated collections indicates that the sites are part of a geographically diffuse, less-intensive industry of quartz procurement that focused primarily on non-bedrock sources. Chronological patterns are apparent. In addition to standard archaeological sampling, a geophysical survey was used to aid in identifying quarry features at the sites and was successful at locating a hearth dated to ca. 2260 B.P. Intrasite analysis found clusters of workshop activities with primary materials being collected from surface exposures and then reduced into early-stage bifaces. While fine-grained analysis of the sites is illuminating, understanding of the sites is only possible by appreciating the quartz industry on the macro-scale.

[12] Stable Isotope Analysis of a Middle Woodland Population from North-central Kansas
This study examines the paleodiet and temporality of a Middle Woodland group from five sites in north-central Kansas. This goal was accomplished by submitting 21 samples for stable isotope ratios analysis (SIRA) and 12 samples for bone collagen AMS radiocarbon dating. Results of AMS radiocarbon dating indicated a temporal range of cal. 349 B.C. to A.D. 376. Results of SIRA indicated mixed dietary patterns. Through visual assessment and statistical analyses, it was determined that their dietary patterns formed two clusters. Results were interpreted in terms of flora and fauna from the archaeological record of nearby contemporaneous sites. Other causal factors for stable isotope distribution were taken into account, including paleopathology, sex and age, time, social stratification, and multiple group usage. Based on the evidence available, it was determined that stable isotope ratio distribution was caused by limited nutritional stress, and a varied consumption of fauna and flora.

Kaufman, Brett (Cotsen Institute of Archaeology, UCLA)
[41] Colonialism Contextualized: From Punic African Empire to Roman Subjects at the Urban Mound of Zita, Southern Tunisia
The evolutionary history of Carthage is characterized by stages such as the Phoenician establishment of this Tyrian colony and its contact with the indigenous Numidian populations (~814-580 B.C.E.), the transformation of the colony at Carthage to an imperial capital (~580-264 B.C.E.), and eventually its collapse and defeat after over a century of war with Rome (~264-146 B.C.E.). Although the destruction of Carthage as a political center marked the end of at least a millennium of autonomous Phoenician-Punic cultural continuity, minimal research has been conducted on the assimilatory or resistive mechanisms adopted by the remnant African Punic populations that persisted for centuries under Roman rule. In 2013, the first archaeological research was conducted at the urban mound of Zita, providing evidence for both Carthaginian and Roman phases. Survey results from the first season have demonstrated an occupation horizon of ~500 B.C.E.–300 C.E., and excavations at the Punic/Neo-Punic child sacrifice precinct indicate that the Neo-Punic population continued to preserve Near Eastern ideological traditions despite their political incorporation into the Roman Republic and Empire.

[84] Lunate Seriation along the Natufian Sequence of el-Wad: Implications for Intra-Natufian Cultural Change
The Natufian culture of the southern Levant represents the transition from mobile hunting-gathering groups to the first Neolithic agricultural societies. While the general chronological span for the Natufian is now well established (15,000-11,500 cal B.P.), most of the major sites remain poorly dated, particularly
with regard to its sub-phasing. The culture was divided into two phases based on seriation of the lunates. The early phase was characterized by Helwan retouched lunates with minimal use of microburin technique and the late phase typified by small, abruptly retouch lunates and more regular use of microburin technique. This passage is also claimed to be marked by changes in various socio-cultural features such as degrees of mobility, architecture and burial practices. However, placing this transition within the stratigraphic sequence and its timing has proven elusive. We present here the detailed stratigraphic sequence of a large sample of lunates and microburins together with a series of radiocarbon determinations from a variety of contexts including living floors, structures and burials from our recent excavations at el-Wad Terrace and discuss their contribution to the understanding of the nature and timing of this transition and its possible relationship to various socio-cultural and paleoenvironmental factors.

[226] Nature of Authority during the Kofun Period from the Standpoint of Iron Agricultural Tools
Iron was a strategic and scarce resource during the Kofun Period (middle third to early seventh centuries A.D.) when a state-level society emerged. For this reason, analyses of the ownership of iron are effective in approach to chiefs’ control over commoners and the nature of their authority. I have analyzed social ranking system as evidenced by mortuary practices and the practical and ritual uses of iron agricultural tools, and observed the following: 1) in the Early Kofun Period (third and fourth centuries) the ownership of iron remained in the hands of high-ranking chiefs who loaned out iron tools to commoners; 2) in the fifth century and after low-ranking elites came to be in charge of loaning out iron tools to commoners, and high-ranking chiefs no longer interacted with commoners. The first is based on non-discoveries of iron tools at ordinary settlements and discoveries of large quantities of iron tools in elite burial mounds. The second is based on the observation that, while non-practical iron tools for ritual use are discovered in high-ranking burial mounds, practical iron tools are discovered in low-ranking burial mounds.

Kawell, Spencer
[138] Lithic Tool Production in a Domestic Context: Analysis of Group B’s Lithic Assemblage at the Minor Center of Waybil
Since its inception, the Social Archaeology Research Program (SARP) has focused research on understanding the roles minor centers play within larger city-state systems of the Maya. During SARP’s 2012 field season excavations were conducted at the site of Waybil, a minor center situated approximately 1.92 km southwest of Minanha in the North Vaca Plateau of Belize. Specifically, Group B located just west of Waybil’s epicenter was the focus of excavations, resulting in the recovery of a large assemblage of lithic artifacts. The proportion of these lithics to other artifact classes as well as the density at which they were recovered would seem to indicate that this area of the site was likely used for lithic production. The activities surrounding the production of these lithics may very well enhance our understanding of how minor centers functioned in a larger city-state system. To garner a better understanding of Waybil as a minor center as well as its relationship with Minanha, an analysis of the lithic assemblage was conducted this past field season with aims to address such issues. The results from that study will be presented as well as their implications for the role of Waybil in the greater Minanha regional system.

[109] Ethiopia MSA Production Chains Early and Late: Gademotta, Aduma, and Shinfa
Middle Stone Age Ethiopia exhibits technological continuity over time and space. Beginning with its early representation at Gademotta at >279,000 B.P., the overall production chain is dominated by Levallois manufacturing techniques. This continues in later time to places not so heavily invested in primary resource acquisition, whether or not the toolstone is obsidian. Here we compare the production chains exhibited at Aduma and Shinfa, which represent occupations near or at the end of the MSA, with that from Gademotta. Shinfa stands out for the diversity of local, or proximate, stream bar chipped stone sources and the opportunistic, rational production strategies dealing with either bipolar cobble reduction or unifacial and bifacial marginal retouch of tabular pieces. Aduma is material source size-dependent too.
with basalt items being local and big; obsidian distant and quite small. Even so, Aduma has general size overlap with basalt and cryptocrystalline silicate points from Shinfa. Other parallels are the Levallois micro-disc cores, and Levallois or bipolar core reduction at Aduma and Shinfa. Regardless of the sites, the point engineering design is consistent: the intent was to develop and maintain a longitudinal plano-convex profile for ease of penetration, and to return to this form whenever possible.

Keach, Levi (University of Nevada, Las Vegas) [332]  
Stone Blades and Social Space: Describing and Interpreting Two Stone Blade Caches at Neolithic Ais Giorkis, Cyprus

Ais Giorkis is an early Neolithic site dated to ca. 7,800 cal. B.C. It is uniquely located in the uplands of western Cyprus. During the 2013 field season, two caches of fine chert blades were discovered. The first cache was composed of 58 blades and three core trimming elements, while the second cache was composed of 26 blades and two shell beads. Both caches have been analyzed, with the second cache receiving refit analysis as well. The results of refit analysis demonstrate that the second blade cache was composed primarily of blades from two large cores of locally available chert. Both of these caches were found in the area northwest of the largest structure currently known at the site, an oval platform. This paper will compare the blades of the caches against each other, as well as blades found in other contexts at Ais Giorkis. In addition to providing descriptive data, this paper will explore the potential implications of these caches on our understanding of social space at Ais Giorkis.

AFTER XOC: Beyond the Olmec

The supernatural Shark Monster played a key role in Gulf Olmec religion. Archaeologist Philip J. Arnold III (2005) relates these predators to creation mythology and makes the case that sharks and their habitat have been overlooked in studies of Olmec iconography. Picking up after the Formative period, where Arnold left off, we examine shark imagery in Veracruz during the Epi-Olmec and Classic periods at Cerro de las Mesas, Las Higueras, and throughout the Gulf Coast in the context of contemporary regional beliefs. The Eastern Sea is associated with women and creation. In this presentation we also look at ways that these perceptions took shape in Classic Veracruz iconography as part of a gradual change in the visual record within a firmly established conceptual structure and cosmology.

Keene, Joshua (CSFA, Texas A&M University) [324]  
Technological and Obsidian Source Analysis of Lithic Artifacts from Veratic Rockshelter (10CL3), Southeastern Idaho

Veratic Rockshelter (10CL3), located in the Birch Creek Valley on the northern border of the Snake River Plain, has long been considered among the most significant prehistoric sites in southeastern Idaho. Initially excavated by Earl Swanson in 1961, this site produced over a thousand stone tools from stratified contexts, including hundreds of diagnostic projectile points ranging from the late prehistoric to the late Paleindian period. Swanson’s original age of the deepest Haskett component is 10,340 ± 830 14C B.P. (WSU-760), making it potentially the oldest known stemmed point site in the region. This initial study combines a recent re-evaluation of the chronometric association of stratigraphic layers at the site with an in-depth analysis of over 1100 artifacts from ten occupation horizons. Artifact types and occupation horizons are also compared with pXRF data to compare tool material with obsidian sources from the Snake River Plain to understand material preferences by artifact type as well as through time. The ultimate goal of this project is to compile a diachronic analysis of technology, subsistence, and mobility variation from Veratic Rockshelter and apply it to what is currently known of Snake River Plain prehistory.

Kehoe, Alice (University of Wisconsin-Milwaukee) [214]  
Wrong Words

American archaeologists seem mired in inaccurate colonialist terminology: garden beds for agricultural fields; forager for scheduled resource harvesters; shaman for priests; chiefdom for cacicazgos, kingdoms, or states governed parliament-style by councils with executive administrators; "prehistory" for pre-colonial histories (thanks, Peter Schmidt); and (thanks, Severin Fowles) "religion" for assumed "sacred" separate from mundane. All these terms derive from 19th-century imperial colonialist discourse, and they are racist and inaccurate. Historicizing American archaeology requires purging our discourse of inappropriate colonialist terms.
Keller, Angela (AECOM)

[252]  *Subtle Traces: Identifying Activity in the Plazas of Actuncan, Belize*

Formal plazas constitute the majority of public space in Maya centers and yet, until quite recently, plazas have not received the same investigative attention as the impressive pyramids and palaces that surround them. This neglect is largely due to the difficulty of investigating public plazas, which typically contain few artifactual or structural indications of their ancient use. Although the identification of activity in ancient plazas is technically challenging, a dedicated investigation of plazas is nonetheless essential to our understanding of how centers functioned in Maya society. Public plazas were the venues for the bulk of a center’s daily activities from ritual, dance, and sacrifice to market trade and the settling of disputes. This paper presents the results of two seasons of plaza-focused fieldwork at the site of Actuncan, Belize combining rapid systematic data collection, soil chemistry analysis, macro- and micro-artifact analysis, remote sensing, and targeted excavations. This research program has allowed us to detect subtle patterns that may reflect distinctive past practices in the plazas of Actuncan.

[34]  *Chanka Settlement Ecology: Disentangling Settlement Decision Making Processes during a Time of Risk in the Andean Highlands*

This paper presents results from recent survey and excavation work from the Andahuaylas region of southern Peru to explore the prehistoric settlement ecology of the Chanka ethnic group. This paper attempts to disentangle settlement decision making processes made by local Chanka populations as they reorganized their settlement arrangements during the Late Intermediate Period (A.D. 1000-1400), a period characterized by a heightened level of environmental, economic and political risk. While traditional models emphasize the salient effect that localized warfare had on settlement decision making during this time, this paper broadens the discussion by considering the role that a major drought and its impacts may have had on the integration and spatial patterning of settlement and subsistence strategies. Using GIS, this paper examines the spatial arrangement of densely occupied residential settlements, as well as subsistence production loci (agricultural, pastoral and agro-pastoral sites), and it attempts to identify and to quantify the importance that a range of cultural and environmental factors had on Chanka settlement patterns.

Kelly, Kenneth (University of South Carolina)

Following the “abolition” of the slave trade in 1807/8 by Denmark, Britain, and the United States, the trade in captive Africans underwent substantial realignments as the now largely “illegal” slave trade continued to service the ongoing demands from Brazil, the Spanish Caribbean, and to a lesser extent, the French West Indies and the United States. The focus of the slave trade shifted from the well-known, and highly visible, forts and castles of the Gold and Slave coasts, and entered a new phase of decentralized trade as American, European, and even African American traders established trading posts on the sheltered rivers of present-day Guinea. By entering into economic and biological relations with local elites, the traders profited from the “landlord-stranger relationship” to develop enduring settlements that continued to engage in the slave trade as late as the 1860s. This paper discusses survey and excavations at three important slave trade ports on the Rio Pongo, and reports the results of this first historical archaeological research program in Guinea.

[143] **Pre-Classic to Classic Period Shifts in the Economic Participation of Women in Hohokam Society**

This paper addresses changes in women’s participation in the Hohokam economy during the Hohokam Pre-Classic to Classic period transition (ca. A.D. 1100). It explores how women’s productive activities may have been differentially affected by dramatic shifts in the regional economy and in residential relationships. In a matter of years, the Hohokam economy transformed from a system reliant on the concentrated production and widespread distribution of specialist-produced pottery to a series of bounded economic spheres centered on irrigation communities. At the same time, Hohokam domestic arrangements changed from open pit house courtyard groups to habitation structures situated within walled compounds. This study combines ceramic sourcing data with extant research on Hohokam communities to investigate changes in female extra-household social and economic interactions. Results indicate that women, who are generally considered the authors of specialist-produced pottery, would have experienced a marked shift in their productive activities. Female tasks, which are generally situated in proximity to domestic spaces, may have become more conscripted and secluded with compound architecture.

[251] **The Embedded Nature and Context of Symbols in the Cahokia Cosmogram**

Following the theme of this session on iconography and ideology, we examine the configuration of Cahokia as expressed in its urban epicenter, and the manner in which this cosmogram accentuates various symbolic elements also evident in other more portable media. Cahokia and other Mississippian towns not only express the multi-layered nature of the cosmos but also provide the cultural context for symbols fundamental to various institutions and cults and practices related to them. This presentation draws on the recent investigations in the Cahokia’s East and West Plazas conducted by Washington University and the University of Bologna as an ongoing effort to better understand this incipient urban center, and to better understand how Cahokia is central to our visions of those other worlds.

Kelsoe, Camilla (University of Pittsburgh), Julia Clark (University of Pittsburgh) and Loukas Barton (University of Pittsburgh)

[23] **The Logic of Ceramic Technology in Marginal Environments: Implications for Mobile Life**

Explanations for the use of pots as beneficial tools permeate the literature of technological diffusion and change. Many arguments focus on the economic merits of pots as critical elements of subsistence in marginal environments, but waver on the relative importance of key variables, specifically return rates associated with resource extraction, investments associated with raw material acquisition and tool production, and trade-offs arising from opportunity costs and scheduling conflicts. For example, while durable pots produce greater returns over time, they likely require significant initial investment. On the other hand, production of expedient, and even ‘disposable,’ pots requires comparatively little investment, but offers little promise of long-term utility. The most efficient production strategy may therefore be predicted by environmental and social constraints, including access to raw materials and fuel, dietary needs, and residential mobility. We adapt an established model of technological investment to operationalize differences between expedient and durable wares under a range of ecological and social conditions. This study has important implications for the use of pottery in mobile populations faced with seasonal scheduling conflicts, tool transport, and both resource variability and uncertainty.

[248] **Integrating/Interpreting Community Ritual Space (Bedrock Mortar Station) and Individual Ritual Space (Shelter) at White Rock Shelters, El Paso, Texas**

The integration of the archaeological record to rock art is critical to the understanding of the site. Chippendale’s archaeological approach of formal and informal methods is utilized to give a preliminary interpretation of the White Rock shelters site in El Paso, Texas. The spatial distribution of features and the concept of visual prominence are used to quantify the location and position of rock art relative to bedrock mortar features suggesting mutuality. Informal methods are employed to suggest context to this relationship. In so doing, this multiple approach to White Rock shelters suggest that shelters with bedrock mortars and rock art were used for both community and individual ritual purposes.

Kendall, Aaron (CUNY Graduate Center)  
[29]  Early Medieval Exchange and Communication Networks in Iceland and Greenland
A quantitative approach exploring the utility of complex network theory is used to address exchange and communication between Norse farm sites in Iceland and Greenland. For this preliminary analysis the artifact assemblages from settlement sites in Iceland and Greenland are compared within the potential framework of an exchange network. Comparing Norse farms of various size and rank with emphasis on the non-local material component allows for testing of the strength of ties that may have existed between farms. Preliminary results indicate that early medieval farms on these islands may have exhibited more tenuous exchange and communication links than previously understood, thus making any existing networks vulnerable to systemic collapse.

Kennedy, Richard [44] see Willhite, Brenton

Kennedy, Sarah (University of Florida) and Nathaniel VanValkenburgh (University of Vermont)  
During the late 16th Century, Peru's sixth viceroy, Francisco de Toledo, ordered that all native settlements be destroyed and their inhabitants resettled into a series of planned towns called reducciones (reductions). Primary sources offer little about the effects of the reducción movement on indigenous populations. Thus, the archaeological study of reducción settlements can provide critical insight into how forced resettlement impacted daily life. This poster presents faunal data from the reducción site of Carrizales on the North Coast of Peru (Zaña Valley). The site contains contexts from both the Late Pre-Hispanic Period and the Early Colonial Period. We compare remains of meat consumption from both occupations to assess changes in household economies presumably due to 1) colonial mita, the Spanish imposed forced labor system; 2) the introduction of small deserted adapted Eurasian animals; and/or 3) the incorporation of Spanish tools during the food preparation process. The pursuit of these lines of research contribute to a better understanding of reducción's impact on Peru's indigenous populations and serve as a valuable case study of how imperial design projects impact the daily life of their subjects.

Kennedy, John (SWCA Environmental Consultants) and Paul Burnett (SWCA Environmental Consultants)  
[265]  The Carter Site (48NA1425): Data Recovery Excavations at a Multicomponent Open Camp in Central Wyoming
The Carter Site (48NA1425) is a multicomponent site located around a terrace of an intermittent stream in central Wyoming. The site is best known for its abundant Late Prehistoric ceramic component recovered during excavations in 1996. These ceramics share an affinity to Uncompaghre Brown Ware from the southern Rocky Mountains and northern Colorado Plateau and hint towards long-distance cultural interactions. In 2012, excavations of over 100 square meters near the previous excavation area added only one ceramic sherd. Three hearth features were documented, including a large pronghorn roasting pit. Other artifacts include butchered faunal remains from bison, pronghorn, and a large carnivore, as well as a sizable number of lithic artifacts. Additionally, an update to the surface record identified Paleoindian and Late Archaic surface manifestations. Here we present a summary of the 2012 findings in the context of the previous work conducted at this site. The picture that emerges is a series of spatially discrete Late Prehistoric occupation areas that are buried in a distinct terrace deposit surrounded by uplands that were periodically occupied throughout prehistory.

Kennedy Richardson, Karimah (Autry - Southwest Museum of American Indian/UCR)  
[142]  Shared Collection Management Issues, Policies, and Goals for Improvement
The Southwest Museum Collection at the Autry National Center has received much commentary from many academics, researchers, community members, and the public about its management policies regarding collections of human remains. Collection management practices have changed over the years since the museum's conception in the early 1900s. Due to changes in archaeological staff and museum professionals, the collection has become misunderstood. Much has been said about the collection without placing it in context. The work I have begun with the Catalina Island Museum collection, as well as others, shows that the Southwest Museum Collection condition is not unique, and there are many institutions in
southern California with shared museum collection policies and shared collections that are also currently rectifying collection practices of the past. I present the shared policies and collections management practices that will be applied to the Catalina Island Museum human remains collection as well as to the Southwest Museum Collection.

Kennett, Douglas (Penn State) [158] Climate Change and the Integration and Disintegration of Postclassic Period Maya Polities

Multiple proxy climate records across the Maya region now indicate that a series of multi-decadal droughts contributed to the asynchronous disintegration of Classic Period polities in the central and southern lowlands between AD 750 and 900. Smaller polities persisted in more coastal locations around the perimeter of the Yucatan Peninsula and in the Northern Lowlands where two centralized states reached their height of power during the Postclassic Period: Chichen Itza (A.D. 950–1000) and Mayapan (A.D. 1100–1448). In this paper we examine the development, resilience, and disintegration of these more centralized polities with the available archaeological and historical data and an integrated climatic record reliant upon atmospheric modeling and proxy climate records for the region. We also examine the economic, social, and political effects of a multi-decadal drought recorded in the Yucatan between AD 1530 and 1560. Based on these historical observations we conclude that multi-decadal droughts in the Northern lowlands undermined agricultural productivity, led to widespread famine and infectious disease, and the depopulation of towns and cities; mechanisms that would have destabilized more centralized polities during extended periods of drought earlier in the Postclassic Period between A.D. 1000 and 1100 (Chichen Itza) and A.D. 1325 and 1448 (Mayapan).

Kerig, Tim (Institute of Archaeology UCL) [187] Population Dynamics and the Flow of Knowledge and Substances: A New Perspective on Flint Mining and the earliest Metallurgy in Neolithic Europe

The paper aims to explain variation in the intensity of flint mining activity and the earliest metallurgy in Europe areas north of the Alps. It will be shown that the development of both industries is strikingly correlated in time. Instead of interpreting this as an indication of direct interconnections (e.g., in a shared market), flint mining and the exchange of copper will both be shown as being effects of / responses to changing population densities. The positive as well as the negative growth of Neolithic populations caused major transformations in the economic networks regulating the flow of technology and raw materials. The population density is derived from the EUROEVOL proxy of summed calibrated radiocarbon date probabilities. The model of the exploitation of Neolithic flint mines is likewise based on summed calibrated radiocarbon date probabilities as proxy for the industry’s activity, while copper use is approached by making use of quantities of copper finds mapped in narrow time slices from all over the area.

Kessler, Nicholas (University of Arizona) and Ronald Towner (University of Arizona) [176] Anthropogenic Landscape Change: Documenting the Effects of Small-scale Historic Logging in Western New Mexico

Archaeological features related to mid-20th Century logging were documented in the El Malpais National Conservation Area (EMNCA), New Mexico. These features include extensive slab piles (generated during the cutting of logs into rough lumber), outbuildings, living quarters, and artifact scatters. Logging was an important part of the western New Mexico economy during the first quarter of the 20th Century, but logging within this area has been little recognized by archaeologists and historians. We utilize dendrochronological, documentary, archaeological, and geomorphological information to illuminate the nature and scale of landscape change related to historic logging in the area. Based on our data, trees
were felled over a brief period during the mid-1940s by local residents. Processing was probably conducted using mobile equipment. Based on the size of the slab piles at the site, these activities significantly reduced ponderosa pine numbers from the logged parcels. More research is needed to determine specific ecological consequences of this relatively small-scale operation, but understanding the details and duration of timber harvesting at all landscape scales is a crucial step toward reconstructing accurate records of historic anthropogenic environmental change.

Ketchum, Sheena (Indiana University)

The Anatolian Double Horns of Consecration? Potstands at Neolithic and Chalcolithic Çatalhöyük, Turkey

The excavations at Çatalhöyük have uncovered an abundance of potstand artifacts which are often rectangular or rounded vertical well-fired clay objects with one or two protruding horn-like points. The potstands have been strongly associated with pottery vessels and cooking, both in terms of their primary context and the interpretation of their use and function. Potstands were likely used in groups of three or four to support the round-bottomed pottery vessels. During the latest Neolithic occupations, at Çatalhöyük, evidence suggests a shift away from the use of interior fixed architectural fire installations for cooking, towards the use of ceramic vessels balanced on potstands, placed over short-term temporary hearth features. The changes in cooking techniques are indicative of shifting patterns in daily life that may have been dramatic. This poster investigates these changes, examining the potstand use, manufacture, typologies, styles, and their relative chronology to gain a better understanding of the gradual transition from Ceramic Neolithic to Early Chalcolithic Çatalhöyük and the temporality of potstands. It poses the question: how did transformed cooking practices alter daily life and rhythms at Çatalhöyük? Without the potstand, where would you stand the pot?

Ketron, Caroline

Variability in North American Paleoindian Lithic Artifact Transport

That early Paleoindians are highly mobile and preferred high-quality toolstone seems apparent from the record. But to what degree is the lithic procurement behavior of early Paleoindian populations different from that of later populations? How does the distribution of fluted points from their geologic sources compare with that of later periods such as the Archaic? Using an expanded sample of fluted points from North America, I calculate the frequency of fluted points distributed in various directions from their geologic sources to see if significant directional patterns are present throughout North America. I then evaluate these results against raw material availability and paleoenvironmental variations across the continent, to see which patterns are specifically Paleoindian. For example, do point distributions and directions of fluted points from their geologic sources correspond to changes in resource availability or conform to least-cost pathways? How much are the directional trends influenced by the distribution of lithic sources on the landscape? Finally, I compare a sample of early Paleoindian fluted points to a sample of late Paleoindian points and early Archaic points, to continent scale diachronic trends in lithic resource procurement.

Key, Alastair, Ignacio de la Torre (University College London) and W. James Stemp (Keene State College)

Is Loading a Significantly Influential Factor in the Development of Lithic Microwear? An Experimental Test Using LSCM

Lithic microwear develops as a result of abrasive friction between a stone tool's working edge and the surface of a worked material. Variation in the loading (i.e., force) applied to a stone tool during its use alters the amount of friction created between these two materials and should subsequently either increase or decrease the level of any wear accrued. To date, however, no comprehensive account of the interaction between variable working loads and wear development has been undertaken. If such a relationship does exist, it may be possible to calculate the loading levels applied to stone tools during their use. Here, we use 30 basalt flakes knapped from raw materials collected in Olduvai Gorge, Tanzania, in a controlled experimental cutting task of standardized duration. Loading levels are recorded throughout with each flake being used consistently with a predetermined load, ranging between 150g - 4.5kg. Laser scanning confocal microscopy (LSCM), coupled with appropriate statistical analysis software, is used to mathematically document the surface texture of the flakes to determine whether variation in loading does in fact significantly affect the amount of wear on the flake surfaces.

[40] Forest, Field, and Fuel: Changing Landscape Use in Iron Age Central Africa

Tropical rain forests play an important role in the diffusion of novel technologies and the expansion of sociopolitical authority during the Iron Age in Central Africa. Rain forests not only provide the basis for the flexible subsistence activities upon which these societies are based, but they also serve as a source of nutrients for agricultural plots and fuel for the production of iron. Archaeological evidence for prehistoric subsistence and iron-production activities in this biome are limited by the taphonomic and logistical challenges presented by tropical vegetation. Acidic soils, high levels of biotic activity, and dense vegetation cover significantly constrain the effectiveness of archaeological survey and excavation. This presentation evaluates changing landscape use during the Iron Age in the Ngotto Forest Reserve, Central African Republic using paleoenvironmental evidence collected from deposits associated with known site clusters. This evidence underscores important links between sociopolitical organization and landscape use that contextualizes regional archaeological phenomena. These results also provide an empirical basis for unpacking the ecological impacts of technological and social change in order to facilitate a clearer understanding of how prehistoric societies shaped modern biomes.

[305] Transformations at a Secondary Center: Survey, Mapping and Excavation at Ucanha

Ucanha is one of two sites with public architecture found along causeway connecting Ucí and Cansahcab. Settlement survey conducted at the site shows that it covered 2.5km² at its apogee in the Early Classic period, making it twice as large as Kancab, the other site with public architecture between Ucí and Cansahcab. Beyond the central plaza, most of the architecture consists of domestic megalithic platforms though the site contains a variety of large features not seen elsewhere in the region. Although the site is similar in layout to Kancab, the site is also unique due to the presence of walls and other features circling the main plaza. These features restricted access to the main plaza either for defensive purposes or to partition a sacred place. Excavations in the central plaza of Ucanha show that the site was occupied by the end of the Middle Preclassic thereby suggesting this lived place was demarcated before the construction of the causeway. Interestingly, the ceramic data from megalithic platforms indicate they were most intensively used during the Late Classic and perhaps were loci for feasting episodes.

[267] A GIS-Based Approach to Modeling the Geomorphology of the Outlet Channel at the Blackwater Draw Site, NM

The Clovis-type site (the Blackwater Draw site) lies within a natural basin that once served as a catchment for flowing springs and stream waters during the Late Pleistocene, providing a water source for the occupants of the Southern High Plains. During episodes of high effective moisture, water flowed out of the basin through an outlet channel into Blackwater Draw. Coinciding with the increasingly mesic conditions of the Younger Dryas, the flowing waters of the outlet channel were obstructed and a pond formed within the basin; the causes of which are unknown. To trace the geomorphologic changes in the outlet channel, this research utilizes GIS-based spatial interpolation to create a series of topographic paleo-surface models from core data collected by C. Vance Haynes, as well as additional data from recent excavations. The geomorphologic changes represented by the surface models, combined with climatological data, may eventually provide a means to understanding the causal agents responsible for the formation of the pond. Additionally, more precise modeling contributes to understanding the parallels of a changing landscape and the human adaptive response at not only the Blackwater Draw site, but across the Southern High Plains.

[33] Tombs, Burials, Cemeteries, and Sacrifice: A Historical Perspective on the Changing Interpretations of Human Remains in the Karstic Maya Landscape
Archaeological interpretations of human skeletal material found in caves have changed over time. Prior to the 1990s, skeletal material discovered in caves was generally assumed to represent deliberate burial. This interpretation fit logically with the almost universal acceptance of cave function as being primarily habitational. The development of a Mesoamerican Cave Paradigm over the past thirty years has discredited the idea of cave habitation. In its place, the ritual use of caves has been stressed. The implications of the cave paradigm have not been lost on cave bioarchaeology. The paradigm has led to a wider consideration of the types of mortuary rituals that occur in Maya caves. The types of rituals that have been interpreted from the archaeological record, documented ethnographically and recorded ethnohistorically include various types of burials, ancestor veneration, and lineage burial. However, it is only recently that the possibility of sacrifice has been considered. This paper will review the major contributions that made way for this paradigmatic shift for bioarchaeological interpretations made from skeletal material discovered in caves.

[235] Geoarchaeological Investigations at Yangguanzhai, a Middle Neolithic Site in North-Central China

This paper presents the results of the first soil-stratigraphic investigation at Yangguanzhai (YGZ), a Middle Neolithic site (~5,500 cal years B.P.) in the Wei River Valley (WRV) of north-central China. Three main soil units are identified. The deepest is a grayish colored Ab horizon, which contains an abundance of Neolithic pottery sherds and may represent agricultural topsoil generated during initial Neolithic occupations. Overlying the Ab horizon is the most well-developed buried soil in these profiles (B2), which is thick, dark brown, and contains evidence of intensive Neolithic occupation. Finally, the uppermost buried soil is light brown, less structurally developed and contains Han dynasty artifacts. Between these buried soils is unweathered sediment, perhaps the result of heightened overbank deposition onto the floodplain and thus indicative of landscape instability in the lower WRV. Based on field observations and corresponding laboratory analysis, it is clear that YGZ inhabitants experienced several shifts in landscape stability and paleoenvironmental conditions, as the site underwent at least three cycles of sediment deposition followed by pedogenesis over the Middle and Late Holocene. Additionally, an interval of landscape instability may have prompted site abandonment between the Neolithic and Han periods, as ~3,000 years are missing in the archaeological record.

[267] Current Research and Investigations at Blackwater Draw, NM

Blackwater Draw Locality 1, a.k.a. the Clovis site, is widely recognized as one of the most significant archaeological sites in North America. BWD is actually a series of sites representing a hunting and camp area used throughout the Late Pleistocene and much of the Holocene. Archaeological investigations at BWD over the last 80 years have revealed an extensive stratigraphic record that established a sequence of archaeological cultures for the Southern Plains and the Southwest, including Clovis, Folsom, Agate Basin, Plainview, Angostura, and Cody as well as Archaic and later prehistoric cultures. This poster describes four avenues of current research by ENMU at BWD that build upon this history and investigate new discoveries: (1) renewed excavations of a Late Paleoindian bison kill in "Isequilla's Pit," (2) investigations into the age and cultural affiliation of the newly discovered Locality X, (3) laboratory excavation of a block of Folsom-age sediment and bone salvaged in the 1960’s, and (4) intensive paleoenvironmental research on BWD and a newly discovered Pleistocene locality to the north. This poster serves as an introduction to the other posters in this symposium, which present aspects of these projects in more detail.

[64] Communities of Foreigners in Roman Cemeteries (1st-3rd Centuries A.D.)

In spite of the massive influx of immigrants into Rome during the Imperial period, there is little information and much debate regarding their demography, living conditions, lifestyles, and burial practices. A growing trend in isotope analysis of human remains from Imperial-era cemeteries, however, presents a new data set for investigation of possible ethnic communities in Rome. Statistical tools available within ArcGIS 10.1 provide a way to objectively isolate spatial patterns in isotope data from individual graves within a cemetery. Using Moran’s I, for example, a statistically significant result ($p < 0.05; z = -2.28$) was found in the strontium isotope values in the Casal Bertone cemetery, which indicates anomalously high values tend to be clustered near low values. Further analysis of the data with Anselin’s Local Moran pinpoints
the location of the low/high strontium clusters in the cemetery. The challenge here is in interpreting the patterns in these osteological data against the historical backdrop of Imperial Rome. At Casal Bertone, spatial correlation in strontium isotope values may reflect a burial community of non-local Romans. This paper integrates osteological, spatial, and historical data to argue that previously unresolved questions about ethnic communities in Rome can be explored using new techniques.

Social Invisibility, Beatification of Death: Investigations of Large Unmarked Early to Mid-Nineteenth Century Cemeteries in Central Kentucky Urban Contexts.

Urban contexts can provide a challenge to researchers investigating historic cemeteries. Changes in land use patterns and an absence of historic records can result in a cemetery being rediscovered during construction. Within early historic cemeteries burial plots also were often reused. Both instances can result in the comingling and fragmentation of human remains. Two large Cemeteries, one in Frankfort and the other in Lexington, highlight some of the issues in dealing with commingled remains. We will address how we have addressed some these issues. The markerless Frankfort cemetery can be interpreted in the context of attitudes toward the working poor in the 1800 to the 1840’s and even today. Analysis of the remains, however, challenges those presumptions. A second case of Eastern States Mental Hospital is presented to contrast how the remains of those institutionalized are treated during the Beautification of Death movement. Descriptions of the “pleasure grounds” are contrasted with the burial context of the actual remains recovered. Each is illustrative of social constructions of death and the resultant recovery of mortuary remains.

Ancient Guinea Pig DNA as a Proxy for Human Migration in the Caribbean.

There are three main models about the human colonization and migration into the Caribbean during the Ceramic Age; north from the Orinoco basin into the Lesser Antilles, into the Greater Antilles followed by a southward movement, and long-term interaction between Columbia and the Caribbean. It is known that guinea pigs were brought into the area by humans sometime after A.D. 500. Studying the genetics of ancient guinea pig DNA can thus shed light on the human migration patterns. We have obtained 5 guinea pig mandibles from pre-Columbian sites in the Caribbean and extracted and amplified mitochondrial DNA from 4 of them. We will clone and sequence parts of the cytochrome b gene and d-loop to investigate the genetic differences between individuals on different islands, which should help to pinpoint the movement of the domesticated species over time. That data can then be used as a proxy for human migration.

New Materials – New Technologies? Postclassic and Early Colonial Technological Transitions in the Nejapa Region of Oaxaca, Mexico

The Nejapa region of Oaxaca, Mexico, has been continuously occupied since the Middle Formative period (800 B.C.). Although there were technological changes over time, no changes were as great as those seen across the Postclassic (A.D. 800-1521) and Early Colonial (A.D.1521-1650) transition. By comparing two sites on either side of this transition, we aim to show how Spanish colonialism impacted the raw materials that people had access to and/or chose to use for cutting tools, building materials, and costume ornaments. While certain materials were replaced (metal vs. stone cutting tools, adobe vs. stone fill construction, imported glass beads vs. locally-made stone beads), the new technologies still fit within the lifeways of Nejapa's native peoples. At the same time, some technologies remained largely unchanged, such as ceramic paste production and the use of stucco in construction. The adoption of new materials and technologies and the continued use of others demonstrate simultaneous restrictions in choice and the availability of opportunities within the politico-economic structures of colonialism. The technological changes also condition how current residents of the region view the past and acknowledge
ancestors, creating a gulf between notions of tradition and modernity.

[80] Archaeology Practicum: Teaching Undergraduates the Pleasures and Problems of Working with Archaeological Collections
Archaeology field skills are taught in any number of field schools in the Middle Atlantic, but post-fieldwork skills can be a bit more challenging to pick up at the undergraduate level. St. Mary's College of Maryland, a four-year public honors college emphasizing experiential learning, recently inaugurated a required course, Archaeology Practicum, to address this need. Partnering with the Maryland Archaeological Conservation Laboratory, the state's curation facility, students in Archaeology Practicum adopt and process an orphaned collection (including washing, labeling, and cataloging); research the materials; write, edit, and produce a major report; and prepare materials for long-term curation. Students learn important curatorial and research skills and responsibilities, new findings are generated about abandoned collections, and collections once considered of little use are made available to the broader professional community.

[96] Heritage and the Underrepresented: The Perspective from Howard University
Heritage studies programs are gaining in popularity worldwide as universities increasingly tap into this burgeoning interdisciplinary field. In the U.S. alone over a dozen universities now offer graduate degrees in heritage studies or feature centers that facilitate interdisciplinary collaboration on heritage issues. These programs all define “heritage” somewhat differently and have varying emphases, for example, museum studies or architecture. At its most fundamental, however, heritage has to do with identity; it is our link to our past and to who we are today. It is from that perspective that it makes the most sense to minorities and other underrepresented students, who otherwise have no reason to enter into heritage fields like archaeology, which are perceived as servicing largely majority—and wealthy—agendas and values. For many first-generation-in-college students, too, these fields lack visible career trajectories leading towards specific jobs. At Howard a successful undergraduate archaeology program was terminated because administrators could not see the significance of archaeology for identity nor its possibilities for employment. New work is now underway, however, to develop a program focusing on heritage as identity. Professionalizing heritage education would help give frame and substance to such programs, while providing a path for all students towards viable careers.

King, Robert (Bureau of Land Management) and Jeanne Moe (Bureau of Land Management)
In July 2013 four determined federal employees, including two each from the Bureau of Land Management and the National Park Service, and a dedicated private archaeological contractor, helped 250 Boy Scouts earn requirements for the Archaeology Merit Badge at the 2013 National Boy Scout Jamboree in West Virginia. It was a wonderful opportunity to teach certain basic information about archaeology while instilling a conservation ethic and an appreciation of what archaeologists do to preserve the nation's past. Planning for this participation began with observations made at the 2010 National Boy Scout Jamboree of how the Archaeology Merit Badge could be better taught. This paper tells what happened in 2013 and encourages seizing other such great opportunities to provide Heritage Education.

[291] Relatedness and Ideology in Middle and Late Woodland Period Societies in the Lower Illinois Valley
Kinship, or relatedness, is a fundamental dimension of social life, structuring and structured by the diverse range of interactions and practices that constitute it. These relations are not solely intergenerational genetic connections; they are culturally constituted over space and time, and may manifest differently depending upon context. Mortuary rituals are one such context in which relatedness may be constructed and represented by social actors. In this paper, I use mortuary and biological
