distance data from Middle (50 cal B.C. – cal AD 400) and Late Woodland (cal AD 400-1000) Lower Illinois Valley sites to investigate the interconnection between funerary practices, relatedness, and ideology over time. Emphasis is placed upon the manner in which these practices produced and materialized indigenous conceptions of relatedness between the living and dead, and amongst the living. Temporal change is then linked to transformations in ideas of community membership and associated ideology.

“Soon the Archaeological World Will Hear from New England”: Maurice Robbins and the Remaking of Massachusetts Archaeology

Although an electrical engineer by trade, Maurice “Doc” Robbins was at the center of Massachusetts archaeology for most of the 20th century. By 1945 he had helped found the Massachusetts Archaeological Society (MAS) and the Bronson Museum. His most notable fieldwork was at the Wapanucket site, where he led intermittent excavations with fellow MAS members from the late 1930s to 1960s. He also published The Amateur Archaeologist’s Handbook (1964), an influential albeit controversial book. Later in his career, Robbins sponsored legislation that ultimately led to the Massachusetts Historical Commission’s creation in 1969. He served as its first Commissioner (1969-1972) and was also the first Massachusetts State Archaeologist (1972-1979). Throughout his career, he worked to stop looting in the state, which may explain his desire to see an archaeological society started that could connect amateur and professional archaeologists. Robbins’ overall success was due in great part to the personal and professional relationships that he maintained throughout his life. He was not the only influential figure in Massachusetts however, which led to disagreement and conflict on various fronts. Through primary and secondary sources, this presentation offers a glimpse of Robbins the man, who helped begin an important chapter in Massachusetts archaeology.

Evidence of Interpersonal Violence in Pleistocene Populations: Introducing a New Skeletal Database of Modern Humans to Test Theories on the Origins of Warfare

The origins of warfare have been argued to extend far into our evolutionary history; however, the actual skeletal evidence of interpersonal violence is quite sparse. Here, we report on the creation of a comprehensive database that contains data on skeletal remains of H. sapiens securely dated to before 10,000 cal B.C. We show that even with a very liberal definition of conflict those sites most often cited in the literature as evidence of “warfare” do not support the assertion of a violent past. This catalog of over 450 sites not only allows for the testing of how pervasive warfare was in the past, but it is the only known, global collection of the remains of modern humans. This database and its eventual online publication in a Wiki-format will provide an exceptional resource available to answer a wide range of anthropological questions.

Whiskey Did Not Build the Aqueduct: New Insights on the Builders of the Los Angeles Aqueduct

The building of the first Los Angeles Aqueduct was a momentous task requiring a tremendous amount of labor. From 1907 to 1913 a total of 57 construction camps were erected along the 225 mile path of the aqueduct. Work camp settings such as these can offer unique contexts for historical archaeologists to explore instances of struggle, exploitation and resistance among workers. Additionally, archaeological research at work camp sites can answer questions about the forces that united or divided workers under the conditions of a temporary work community. Previous research on the Alabama Gates aqueduct construction camp has indicated that the camp layout served to divide workers based on their perceived higher or lower class position. Worker responses to these types of scientific management strategies played a vital role in the foundation of class identities and the negotiation of improved working conditions over time. This poster will discuss the archaeology of construction camps along the Los Angeles Aqueduct with a particular focus on the more ephemeral camps situated in its southern sections.

[310]  Migration and/or New Adaptive Possibilities? Population Growth and Decreasing Residential Mobility in Eastern Finland during 4500-3500 B.C.E.
In about 3900 B.C.E., the waters of the massive Ancient Lake Saimaa in eastern Finland burst through its end moraine, forming a new outlet, the Vuoksi River. Consequently, the water level sank by about 2-4 meters. Shortly after that, the archaeological record in Finland shows signs of new cultural traits. These changes are visible in the style of pottery, burial customs, house building traditions and in the substantial increase in exotic materials which indicate new, long-distance trade networks. This paper is based on a case study restricted to the period 4500–3500 B.C.E. The study area covers about 5,600 km² in the northern parts of Ancient Lake Saimaa. The focus is on the changes in population numbers, in long-term patterns of residential mobility, and in subsistence strategies. The following questions are considered: Did a new group of hunter-gatherers migrate from the contemporary Russian side of the border to Finland at the beginning of the 4th millennium B.C.E.? Or did the changes come as a consequence of local developments due to a climatic optimum? Did the formation of the River Vuoksi offer new adaptive possibilities? Did a “travelers and processors” kind of competitive situation between hunter-gatherer groups affect their subsistence strategies?

[194]  Abundant Exotics and Cavalier Crafting: Obsidian Use and Emerging Complexity in the Northern Lake Titicaca Basin
During the Middle and Late Formative periods (500 B.C.- A.D. 300), Taraco and Pukara became major centers in the northern Lake Titicaca Basin of Peru. Recent research has revealed similar economic patterns for both sites, which include the importation of obsidian from the Chivay source located 200 km to the west. Although it is exotic to the basin, obsidian is ubiquitous in recently excavated contexts at both Taraco and Pukara, and its purposeful accumulation corresponds with increased investment in corporate architecture and supra-household food sharing. Additionally, analysis of obsidian debitage indicates that “cavalier” craftspeople made few attempts to conserve or recycle obsidian during the preliminary stages of manufacture, a pattern that has been linked with resource abundance. We argue that this intentionally wasteful behavior further reflects the status of these centers as primary nodes in region-wide obsidian exchange networks, and may have contributed to their attractiveness as places to settle during the Formative period. These results highlight the significance of abundant exotics in the formation of regional centers and multi-community polities, and underscore the importance of monitoring patterns of production and use in the analysis of exotic goods.

The middle Mekong river basin rests in an intermediate position between China to the north, Vietnam to the northeast, and Thailand to the southwest. This location places the basin at the crux of a longstanding archaeological debate regarding the routes for the introduction of agriculture to Southeast Asia. This paper intends to provide a greater understanding of the origins of agriculture in Southeast Asia by looking at relative access to arable landscapes in the Mekong basin in the vicinity of Luang Prabang in northern Laos. Initial assessment of landscape variability in the Mekong basin, using topographic wetness indexes, suggests that there may have been a transition to lowland horticulture from highland foraging during the Middle to Late Holocene. In this paper, we use GIS software to create a more robust model of access to arable land of sites in our database in terms of relative rice and millet outputs. These relative outputs are then used in an inter-site comparison of over 80 Middle and Late Holocene sites based on the arability of their surrounding landscapes to help assess and infer cropping practices by early plant cultivating societies in the region.

Klaus, Haagen (George Mason University)
[28]  The Social Bioarchaeology of Commingled Remains: Theoretical, Methodological, and Interpretive Approaches from Colonial Peru
In recent years, greater engagement with disarticulated and commingled human remains in archaeological settings have increasingly shed light on the interactions between the living and the dead and the frequently exotic formation processes underlining these complex depositional contexts. In this paper, I review the evidence of commingling in the Colonial-era cemeteries of Eten and Morrope, Lambayeque, Peru. Archaeothanatological study of more than 800 burial contexts between the two sites carefully reconstructed mortuary programs, and reveal highly contrasting patterns of commingling, spanning ossuaries, secondary burials serving as ‘offerings’ to the recently deceased, and reburial of thousands of individual skeletal elements.

Quantitative and social interpretations of the internal organization, selectivity, and distribution of commingled contexts indicate the relationships between the living and the dead were very different in these two nearby native communities. These funerary practices were shaped by unexpectedly dynamic social, political, and economic factors in Colonial northern Peru -- thus shedding light on how contextualized and theoretical approaches towards commingled remains provide key perspectives on ideology, meaning, social structure, agency, and lived experiences in the past.

[205] Can Small Sites Stem the Spread of Inequality? Khubu la Dintša and Local Dynamics in Iron Age Botswana

The polity of Bosutswe (700-1700 A.D.), located near the Kalahari Desert, linked trade from the Indian Ocean to the African interior. Surrounding Bosutswe were smaller hilltop settlements, which supplied it with food and domesticates, managed grazing and agricultural lands, provided raw materials such as lithics, and served as settlement areas for traders coming from around the region. Khubu la Dintša (1220-1420 A.D.) is one of these smaller sites. 1220-1420 A.D. was a time of spatial and material distinction between elite and non-elite at Bosutswe; however, KLD also had numerous prestige items. The connections between the Bosutswe elite and the occupants of KLD were significant enough to warrant social and political alliances that allowed access to status goods. Long-distance trade, the development of a prestige goods economy, its coexistence with traditional forms of status, environmental limitations, shifting herding strategies, and regional dynamics provided opportunities for KLD. As social ties were necessary to secure economic relationships, inclusion into elite identity constrained the degree to which inequality was developed in the hinterland. The exclusivity of the elite identity at Bosutswe and inclusion of hinterland people provide a dynamic look at the social, political, and economic dimensions of social complexity on the Kalahari frontier.

[129] Fishing for “Lucky Stones”: Presence of Otoliths in Brazilian Shell Mound Sites

Otoliths are concretions of aragonite located in fish neurocrania. They have been used by many populations as charms, medicine, and raw material for jewelry. These elements are commonly found in shell mound and midden sites, and are usually seen as just standard components of the fish skeleton, being deposited as a by-product of fish processing and consumption. Research at one cemetery unveils new hypotheses for use of otoliths by coastal populations.

[198] Avoiding ‘state-ness’ in Iron Age (1200-586 B.C.E.) southern Jordan: Settlement patterns from marginal landscapes associated with autonomous social organization

Iron Age polities of southern Jordan have been variously portrayed as states, chiefdoms, and other complex political formations. While most archaeological studies of this region have focused on the relative ‘state-ness’ of regional Edomite polity formation, other forms of sociopolitical organization near the edges of these polities have taken a backseat to issues of the state. This paper uses survey data from a 2009 survey of the Wadi al-Feidh in southern Jordan to examine the relationship between regional states and local communities living in politically and environmentally marginal zones. Employing an intensive survey methodology, surveyors recorded a wide range of both sites and ‘off-site’ features previously unrecognized in the rough and rocky landscape of the Wadi al-Feidh. Overall, these findings suggest that
Iron Age communities strived to maintain relative autonomy from the state through their choice in settlement locations, subsistence practices, and local social organization.

Knack, Jeni and Sarah Nava

[198] The Effects of People and Nature Upon One of Santa Catalina Island’s Largest Villages

First historically recorded 1602, the largest prehistoric village site on Santa Catalina Island, at the location of what is known today as Two Harbors, has been explored repeatedly since the late 1800s. These projects have been documented through maps, which delineate the boundaries of this important village, yet the perimeters have been drastically changed from one researcher to another. This paper will discuss the differences that can be discerned between the various historic maps, and it will explore the impact of both humans and natural erosion processes upon the site. Digitizing the historic maps made by previous researchers utilizing the geoprocessing capabilities of ArcGIS software enables comparisons of these maps to be made not only with each other, but with survey data collected during the 2013 field season of the Pimu/Catalina Island Archaeology Project (PCIAP), providing a more accurate and detailed depiction of the village.

[127] Seafaring and Seafarers: Quotidian Events and Centennial Patterns on Bronze Age Cyprus

A renowned Australian archaeologist once stated that "The Cypriote has never been a great sea-farer … nor has he been a keen fisherman, until the coming of dynamite". While that may to some extent have been correct about seafarers in the Early Bronze Age, by the Late Bronze Age this was certainly not the case. From Middle Bronze Age models of boats to Late Bronze Age shipwrecks, as well as a wide range of other material and documentary evidence from or about Late Bronze Age Cyprus, it is clear that people on the island at that time had become deeply involved in maritime activities as part of their everyday, actions that became patterns which set standards for production and exchange throughout the Late Bronze Age. This paper discusses a range of relevant evidence that calls into question not just the statement quoted, but the views - spoken or unspoken - of many other archaeologists working in the Late Bronze Age Mediterranean.

[199] Little Sotol: A Longterm Archaic Earth Oven Facility on Dead Man's Creek

The Little Sotol site (41VV2037) located in the Lower Pecos Canyonlands of southwest Texas is an Archaic earth oven facility where occupants baked lechuguilla bulbs and sotol hearts with hot rocks. The site consists of a two-meter-deep burned rock midden in front of two small limestone caves overlooking a secondary tributary within Dead Man’s Creek canyon, which drains into the lower Devils River. Macrobotanical remains of lechuguilla and sotol, plant processing tools, and remnant earth oven beds were identified within burned rock midden and cave components. Radiocarbon assays range from approximately 5000 B.C. to A.D. 1200. The 6000-year record of burned rock discard preserved at the Little Sotol site allows for the examination of change in the utilization of earth oven technology over time. It is argued that the higher degree of fracture in burned rocks relates to the increased intensity of plant processing in earth ovens. The increased landuse intensity from the end of the Early Archaic to the Terminal Archaic periods fits the model of continental demographic pressure. The Little Sotol site demonstrates the dynamic relationship between populations and the landscape, and the changing role of earth oven technology over time.

Knell, Edward (California State University, Fullerton) and Matthew E. Hill (University of Iowa) [166] Late Paleoindian Cody Complex Tool Assemblage Variability
Archaeologists are acutely aware that the types of tools found at sites vary considerably across time and space. For example, some assemblages are dominated by projectile points and others mostly have retouched flakes. Why this variability occurs at the site level is sometimes clear and other times it is not. More interesting though, is how and why tool assemblages vary at the regional-scale. In this paper we present results of a pattern recognition-based study that evaluates how late Paleoindian Cody complex tool assemblages from 34 sites and components of sites in the Northern and Northwestern Great Plains varied by site type, season of site occupation and environmental zone (i.e., plains grasslands, foothills-mountains, alluvial valleys), and the effects these had on tool assemblage composition. Through this study we gain important insights regarding the causes of tool type variation and, ultimately, how Cody complex hunter-gatherers organized their lithic technology and land-use strategies.

Knierim, Rebekka and René L. Vellanoweth (California State University, Los Angeles) [163] Residue Analyses from a Ceremonial Stone Mortar on San Nicolas Island, California
Excavations at the Tule Creek Village site (CA-SNI-25) on San Nicolas Island have revealed a ceremonial complex dating to the Late Holocene. Features including faunal burials, a hearth row, ritual implements such as crystals, ochre, effigies and pendants; and discrete refuse pits surrounded by culturally sterile dune sand comprise much of this area. Additionally, a stacked stone feature was recovered less than one meter from a juvenile double dog burial. This stone feature consists of a sandstone mortar inverted over an unmodified piece of basalt resting on a serpentinite disc pestle. Results from several residue analyses reveal that a mixture of raw fish and mussel was prepared in the sandstone mortar. As partially digested fish bones were located in the stomach areas of the nearby double dog burial, we suggest that the implements in the stone feature may have been used to administer food to the dogs shortly before their deaths. These recent findings may thus help to shed more light on the important though little understood role of dogs in ritual practices among the people of the California Channel Islands.

Knight, Charles (University of Vermont) [91] The Production of Biface Blanks as Part of Macrocore and Polyhedral Core Reduction Sequences at the Zaragoza-Oyameles Obsidian Source Area, Puebla, Mexico
Intensive, systematic surface survey of the Zaragoza-Oyameles region in Puebla, Mexico, has identified variation in the methods of obsidian extraction and the commodities produced. Reduction sites at and away from the quarries indicate that intense macrocore, polyhedral core, and biface production was carried out. Non-quarry sites and non-site areas have also resulted in the collection of significant numbers of projectile points, scrapers, ceramics, and ground stone. While the locations of bifacial production loci are typically separate from core production loci, there is strong evidence to suggest that the production of at least one type of biface blank was part of the core reduction sequence, indicating that a type of linked-sequencing was practiced in the source area. Material from one obsidian extraction area in particular was utilized for both core-blade and bifacial reduction. An analysis of surface debitage recovered from several contexts associated with this extraction area is presented to investigate the connection between core-blade and bifacial reduction at the Zaragoza-Oyameles obsidian source area.

[317]  The Identification of Genetic Variation in Ancient Maize: Preliminary Results
The assignment of archaeological maize to modern-day races based on morphological characteristics is being viewed with increased skepticism in light of recent advances in ancient DNA (aDNA) technology. However, rather than attempting to match ancient variants to modern indigenous races, it is proposed here that comparing haplotypes of ancient variants would be a more informative endeavor. Despite the fragmentary nature of aDNA, it is possible to extract enough intact segments to develop haplotypes that could identify variation within and between populations. This study focuses on single nucleotide polymorphisms (SNPs) on the plastid genome. Maize cobs selected for this pilot study are from Range Creek Canyon and Glen Canyon, Utah. Specimens were processed in the O'Rourke Ancient DNA Laboratory at the University of Utah. This poster will review the project’s main objectives, methodology, and results.

[299]  Neandertal Sexual Division of Labor Revisited
Sexual division of labor (SDL) is nearly universal among ethnographically documented foraging societies. Recently, it has been argued on largely archaeological grounds that Neanderthals lacked SDL, a distinction that may have played a significant role in their extinction during OIS 3. An absence of SDL among Neanderthals has also been used to reconstruct dimensions of their social organization as well as of their psychology. Using the expectations outlined in these studies, this paper reviews evidence published over the last decade to evaluate its impact on the view that Neanderthals lacked SDL. Using new information about 1) nutrition and hunting strategies; 2) trauma patterns; 3) evidence for complex technology; and 4) spatial organization of sites, we suggest that it is now more difficult to argue that Neanderthals lacked SDL, which has important implications for how we should think about their disappearance as a distinct population, as well as for the timing and ultimate origins of SDL during the evolution of the genus Homo.

Knudson, Kelly (Arizona State University)
[303]  Integrating Identities in the South Central Andes: A Model for Examining Intersections of Biological and Cultural Identities through Bioarchaeology and Biogeochemistry
Integrating social theory with sophisticated methods, bioarchaeologists are well equipped to investigate the complex relationships between biological and cultural identities in the past. Here, we explore the integration of various identities during the Andean Middle Horizon (~A.D. 500-1100) and Late Intermediate Periods (~A.D. 1100-1400), focusing on the San Pedro de Atacama oasis of northern Chile. These periods encompass the expansion and collapse of the Tiwanaku polity as well as environmental change, including a severe drought. By combining multiple lines of bioarchaeological and biogeochemical evidence, we examine how biological and cultural identities were utilized and modified during this tumultuous time. Here we explore this question using evidence from cranial modification practices and the mortuary assemblage, both culturally constructed, and from discrete traits and isotopic analyses, which provide insights into the biological relationships and geographic origins. These data reveal a population where cultural identities were often constructed in opposition to as well as in accordance with underlying biological and geographic differences. As such, this integration of multiple lines of bioarchaeological and biogeochemical evidence with social theory has the potential to provide a complex and nuanced view of biological and cultural identities in the past.

*Head and Legs for Dead People, Meat for Mourners: Animal Sacrifice Practice of the Xingnu Tombs at Duurlig Nars in Mongolia*

The purpose of this research is reconstructing the animal sacrifice practice at the Xingnu mortuary rite during the 1st century A.D. and revealing the socio-political meaning of the practice. Practices of animal sacrifice by the Xingnu people have been detected through faunal assemblage from tombs at Duurlig Nars in eastern Mongolia. From the T2 tomb, which is the largest of the group, 306 horse bones, 288 sheep bones, and one cattle bone were yielded. Most of horse bones (MNI 13) and sheep bones (MNI 25) were placed on the top of the coffin in the very unique way. Head and forearm bones (from radius to phalanges) were arranged in an X shape, and the other parts of body were never found. After comparing this faunal assemblages with that from other small tombs from the site, we suggest that horses and sheep were rather sacrificed as offerings during the mortuary rite, than offered as food for the dead. It seems that the meat from sacrificed animals were distributed to the mourners and consumed during the rite as a part of communal eating. Heads and forearms have symbolic meaning for the afterlife of the dead and were displayed in special way.

*Modeling Long-Distance Migration in the Village Ecodynamics Project*

While for more than a century archaeologists and sociologists have been studying short- and long-distance mobility in societies, tracking prehistoric migration networks remains a challenge. This paper aims to model long distance migration in the Village Ecodynamics Project (VEP) agent-based modeling framework. The VEP developed a multi-agent computer simulation to model the settlement, subsistence, economic, and sociopolitical dynamics of Pueblo societies in the central Mesa Verde and northern Rio Grande from A.D. 600 to 1600. The yearly potential maize productivity dataplans in the simulation, and its representation of vegetation, water, and animal resources provide a virtual test-bed for studying the long-distance movement of households (agents) between the two areas. Our approach for generating the mobility patterns and paths of the socially connected households with extensive exchange networks combines the FETE approach by White and Barber along with a method for adjusting the calculation of the most probable routes, taking into account direction, duration, defense, and dependency factors. This 4-D method improves the realism of the human migration by including the prior estimation of challenges along the journey. Paths that may seem difficult because of their challenging terrain may be selected by a migrating group for their added security.

Kocer, Jacqueline

**Gallina Identity: Examining Projectile Point Style and Raw Material Choices in the Shadow of Chacoan Complexity**

The Gallina (A.D. 1050-1300) of northwestern New Mexico exhibit a suite of artifacts distinct from those of the contemporaneous Ancestral Puebloan world. Projectile point style and morphology can be used to understand group identity and complexity through the examination of specialization and standardization. In contrast to the homogenous nature of Chacoan assemblages, the Gallina exhibit more variety in
Abstracts of the SAA 79th Annual Meeting

Projectile point styles including those that may have been recycled from Paleoindian or Archaic contexts. Comparing this behavior and stylistic variation between samples from Pueblo Alto and Gallina demonstrates the degree to which the Gallina differed from their socially stratified neighbors. Furthermore, raw material choices evidenced through visual sourcing and XRF highlight contrasts in stone tool procurement between the two culture areas. In order to examine identity within the Gallina themselves, western, central and eastern site assemblages are also compared. Ultimately, spatial proximity to Chaco may impact identity between these occupation zones.

Koenig, Charles [199] see Black, Stephen

Koenig, Charles (Texas State University - San Marcos, Texas) and Stephen Black (Texas State University - San Marcos, Texas) [199] Dead Man's Delight: New Approaches to Excavating, Mapping, and Sampling Burned Rock Middens
Burned rock middens—earth oven facilities—occur in various regions across North America and the world. The cultural processes creating a sizeable BRM (hundreds of earth oven construction and use cycles) result in massive palimpsests—nearly homogenized masses of ash, charcoal, FCR, and other detritus often representing thousands of years of intermittent use. These palimpsest features are key to understanding the prehistoric record, yet very time consuming to excavate using traditional archaeological approaches. Therefore, we asked: what can and should be learned from these features; and, how can we expediently excavate and sample BRMs to obtain needed data? In 2012, Texas State University excavated three BRMs along Dead Man's Creek, a Devils River tributary in southwest Texas, to develop an effective excavation methodology to collect data to address how much food was processed and over what span(s) of time? Our approach involved: 1) trenching BRMs and excavating in natural layers; 2) excavating "rock columns" to quantify the amount of FCR; 3) flotation to recover economic species for radiocarbon dating; and 4) Structure from Motion photogrammetry for mapping. These techniques proved effective for quickly excavating, mapping, and sampling BRMs, as well as estimating the amount of processed food.

Kohler, Tim (WSU/SFI/CCAC) [289] Prolegomenon: VEP II, Almost in Retrospect
The Village Ecodynamics Project in toto, now in its 12th year, was originally concerned with only one, and now two relatively small study areas in the southwestern United States. The questions we were asking, however—and which we address in the subsequent papers—have been explicitly posed in the broader context of demographic and environmental change in the Southwest as a whole. In this prologue to the final VEP symposium, we provide the macro-regional context for the papers that follow. This context includes (1) reconstructions for temperatures over the last 2000 years in the northern hemisphere; (2) crude birth rates and life expectancies proxied from sets of human remains for the entire Southwest; (3) the architectural tree-ring record for the Colorado Plateau and its relationship to the reconstructed demographic profiles in our study areas; (4) osteological records of violence for the VEP study areas, compared with previews of demographic and paleoproductivity reconstructions to be presented in the papers that follow; and (5) data sources permitting the inference of migration from Southwest Colorado to the northern Rio Grande in the AD 1200s in conjunction with the general depopulation of the northern Southwest.

Kohut, Lauren (Vanderbilt University) [150] Scales of Analysis and Spaces of Interaction: Understanding Conflict and Alliance during the Late Intermediate Period in the Colca Valley, Peru
Widespread fortification during the Late Intermediate Period (LIP, A.D. 100 –1450) in the highland Andes has traditionally been interpreted as evidence of internecine warfare and regional fragmentation. However, much of what we know about the LIP is derived from large regional surveys, a scale that is insufficient for examining the local patterns of integration and affiliation that formed the basis of daily life
for communities during this period. This paper presents preliminary results from a micro-regional survey of hilltop fortifications (pukaras) in the Colca Valley and argues that within these broader patterns of fragmentation, there is evidence of alliance and affiliation. Drawing on spatial analysis, architectural mapping and ceramic data, I suggest that fortifications in the Colca Valley were integrated into a valley-wide alliance network. These physical spaces both protected communities from external threat and linked households through quotidian social and economic practices. Additionally, fortifications likely served as nodes of inter-site communication, further coordinating settlements in response to defensive need. While fortification during the LIP signals fragmentation at a regional scale, this paper brings together multiple lines of evidence to focus on the meso-scale practices of affiliation and cooperation that existed within broader patterns of regional fragmentation.

Archaeological Psychoacoustics and Auralizations: Theoretical Concerns; Practical Examples

Archaeoaoustic provides a channel through which experiential aspects of past human life might be accessed. Knowledge of physical dynamics, derived from the material remnants of past places, objects, and other artifacts of human actions, enables present-day evaluation of ephemera such as sound. Psychoacoustics, the science of sonic perception and cognition, can be employed in archaeological research to estimate human experiential implications of acoustic dynamics of environments, spaces, and objects. Experiential estimations may be made by applying findings from relevant experimental studies, or by conducting site-contextualized subjective experiments, either in situ where conditions permit testing, or in the lab using computational simulations known as “auralizations.” Although such sonic reconstructions are potentially useful as research tools and for knowledge sharing, as with any virtualization of reality, interpretative and presentational factors are problematically intertwined. Auralization might, therefore, be considered a "mode of engagement" with archaeological data. To illustrate theoretical concerns, methodologies, and applications, case-study examples are given here, based on data from acoustic measurements and auditory localization experiments conducted within the ceremonial architecture at the Andean Formative complex of Chavín de Huántar, Perú.

The Core of the Problem: Soil-Geomorphic Studies at the Aztalan Site

This poster illustrates the preliminary results of a program of soil coring and soil geomorphic characterization conducted at Aztalan State Park and National Historic Landmark in southeastern Wisconsin. The park harbors the remains of a Late Woodland/Mississippian palisaded mound and village complex dated to A.D. 1050-1250 that includes two reconstructed platform mounds, remnants of a third unconstructed platform, and a natural knoll-like feature. Although the site has been the subject of archaeological investigations for more than 150 years, no large scale subsurface sampling for the purposes of geomorphic characterization has been conducted. The coring program reported here was designed to address this need. A truck-mounted Geoprobe was used to sample selected depositional environments in several different site locales. First, deposits adjacent to the west bank of the Crawfish River were sampled in order to determine the extent of anthropogenic filling identified during excavations conducted in 2011. Second, intact portions of the two reconstructed platforms, the single unconstructed remnant, and the knoll were sampled also. Finally, additional cores were extracted from several other site areas to test for the presence of remnant aboriginal borrow pits and to aid compilation of a general soil-geomorphic characterization of the site.

Kolvet, Renee (Engineering and Environment, Inc.)

Social Isolation and the Civilian Conservation Corps (CCC): Case Studies from Nevada

Agriculture has been critical to our nation’s development. Following the Gold Rush, Americans migrated en masse to the semi-arid West to mine or farm the land, despite limited water resources. By the early 20th century, overgrazing and repeated droughts and erosion had severely compromised the public domain in the West. The CCC (1933-1942), a popular New Deal Program, was created by President Franklin D. Roosevelt during the depths of the Great Depression to rehabilitate the land and provide jobs
for unemployed young men. The CCC in Nevada helped federal agencies impound snow melt, slow ravaging flood waters, and tap new sources of water. Main camps were usually built in proximity to railheads; however small, temporary (spike) camps were established near watersheds, and in remote valleys and wooded mountains. Social isolation was an ongoing problem for enrollees from eastern cities and urban areas. Away from their families, recreational amenities, friends, and women, many men suffered from loneliness and boredom. This paper examines a handful of remote sites and the extra challenges faced by enrollees and camp administrators (i.e., the Army) entrusted with their welfare.

Komes, Lindsey (Northern Illinois University) and Winifred Creamer (Northern Illinois University) [10]

LA-ICPMS Analysis of Clay and Ceramics from San Marcos Pueblo

Laser ablation – inductively coupled plasma mass spectrometry will be used to analyze the clay used to make pottery at San Marcos Pueblo and a sample of clay from a nearby source. San Marcos Pueblo is an archaeological site in the Galisteo Basin, New Mexico, near Santa Fe. Helene Warren (1979) stated that San Marcos was a production center for glaze C pottery. By testing the various elements present in the clay of sherds from the site and comparing them with the clay sample, I can determine whether the clay from the glaze C ceramics matches the clay source sample, confirming Warren’s view. Testing samples of all glaze ware present at the site (A-E) will make it possible to see whether ceramics are likely to have been produced at San Marcos during all periods of occupation, or only during Glaze C times. These results complement existing analyses of Rio Grande glaze wares.

Kondyli, Fotini (Brown University) [36]

Beyond the Map: Exploring Socio-economic Networks on a Byzantine Island

Beyond eye-catching maps and complicated graphs, digital landscapes allow us to explore and visualize networks of connectivity between individuals, social groups and political entities in the past. I study possible connections among people and places in the Byzantine world, placing emphasis on non-elite communities and their role in socio-economic and political networks. Focusing on the island of Lemnos in the northern Aegean, I consider different avenues of connectivity that vary from social practices, such as marriages and inheritance patterns, to defensibility, accessibility and visual contact among sites, and to economic and political affiliations among different social groups. To study and visualize these multi-scaled and constantly shifting networks, I employ a variety of spatial analysis tools and methodologies, such as GIS-based applications, connectivity and network theory. My analysis is equally informed by survey data on the region, medieval census, ethnography and old maps. The digital visualization of Byzantine Lemnos highlights multi-layered and complex relations among individuals, and among sites and different social groups. It further emphasizes individual choices and group strategies in population movement, spatial organization and exploitation of the landscape. Finally, it permits a better understanding of the island’s participation in the political and socio-economic networks of the Mediterranean.

Konwest, Elizabeth (Indiana University, Bloomington) [293]

Exploring Community: Recent Excavations in Nejapa, Oaxaca

During 2013 field investigations as part of the Proyecto Arqueológico Nejapa/Tavela (directed by Stacie M. King), I led excavation teams at a group of sites located in the Nejapa Valley of Oaxaca, Mexico. The chosen sites are located within one kilometer of each other and based on ceramic surface collections and test pit data, all date to the Postclassic period (A.D. 900-1521). By targeting residential architecture, I hope to further investigate findings from previous field seasons that indicate that a shared community identity connected residents of the ceremonial center of La Amontonada and other nearby archaeological sites into a sociopolitical unit during this period. Using the premise that communities of practice would be physically manifested, I will draw on several lines of evidence including ceramic and lithic analysis, architectural patterns, and GIS data to discuss community identity and how that influences political and economic organization.

Kooiman, Susan (Michigan State University)
A Multidimensional Approach to Functional Pottery Analysis: A Case Study in the Upper Great Lakes of North America

A recent trend in ceramic analysis has been to use proxy observations to understand prehistoric vessel functions, such as culinary practices and secular versus ritual activities. This approach stands in contrast to the more traditional analyses that have focused on the social and spatiotemporal implications of stylistic attributes, and it serves to expand the breadth of information that can be gleaned from pottery. Building on this, a multidimensional approach was used to investigate diet, cooking practices, and functions of pottery vessels from the Middle Woodland Naomikong Point and Late Woodland Sand Point sites in Michigan’s Upper Peninsula. Physical characteristics and the presence and locations of use-alteration traces (such as carbonized food remains and exterior sooting) were used to determine the technical functions of the vessels and revealed differences in cooking practices between the two sites. Variations in provenience and use-alteration traces suggest a distinction between utilitarian and ceremonial pots based on vessel size. Lipid residue analysis aided in pinpointing specific resources cooked in the vessels, laying the groundwork for a deeper understanding of Upper Great Lakes Woodland subsistence.

Koons, Michele (Denver Museum of Nature and Science)

Internal vs. External: An Examination of Moche Politics through Similarities and Differences in Ceramic Style

In this paper I present an analysis of Moche ceramics from three valleys. The goal of this study was to elucidate aspects of the Moche political landscape and craft production by examining external (surface decoration) vs. internal (technological) style. Design and petrographic analysis of Moche IV, V and Late Moche ceramics from the Chicama Valley (Licapa II, El Brujo, and Cerro Mayal), Jequetepeque Valley (San José de Moro), and Moche Valley (Huacas de Moche) indicate that similar surface designs, yet different internal composition suggest shared ideology among the centers, but local ceramic manufacturing. These data, along with other information, implies probable political alliances and/or religious affiliations, but indicates that each center was locally managed and controlled. I also identified traded or exchanged ceramics from the different sites, which show that relationships were maintained between people from various centers. Additionally, I examined well-contextualized radiocarbon dates associated with Moche IV, V, and Late Moche ceramics from these sites. This analysis shows where the different ceramic styles first appeared and when they were adopted at other Moche sites. Overall, this study of Moche ceramics helps demonstrate that the Moche political landscape was composed of individual site nodes in a complex dynamic network.

The Place of Palma Imagery in Classic Veracruz Iconography

Of the three costume elements associated with Classic Veracruz ballgame ritualism, the palma is the most restricted in time and space, appearing largely in areas associated with the Tajín realm at its apogee. Further, the imagery of the palma may be shown to relate closely to the monumental sculptural repertory found at El Tajín. This essay will attempt to place palma imagery more firmly in the Tajín iconographic system, showing how the cult of ballcourt decapitation, so important to palma imagery, defined in part the political system centered on Tajín. The essay proposes that like the yoke, the palma was emblematic of certain high political offices that oversaw ballcourt decapitation and other crucial legitimating rituals of Classic Veracruz polities. These offices are similar to those of other more well-known Mesoamerican political systems, and comparisons between these systems may provide clues to Classic Veracruz political organization.

Paleoindian Occupation of the Puget Sound Lowlands: Preliminary Findings from Data Recovery Excavation at the Bear Creek Site (45KI839), Redmond, Washington

Kopperl, Robert (SWCA Environmental Consultants), Christian Miss (SWCA Environmental Consultants), Kenneth Ames (Portland State University), Charles Hodges (Pacific Geoarchaeological Services) and Amanda Taylor (Pacific Lutheran University)
The Bear Creek site in suburban Seattle, Washington remains the only archaeologically excavated, stratified site in the Western Washington lowlands yielding Paleoindian artifacts. Intensive data recovery excavations in 2013 produced abundant data on lithic technology and local and regional site formation processes at the Late Pleistocene-Holocene transition. Diagnostic lithic artifacts share affinities with several Western North American Paleoindian traditions. Horizontally, discrete concentrations of debitage suggest repeated use of this place by small groups of people using a variety of lithic raw materials. Excavation coverage across a wide area also highlights the complexity of post-depositional processes following this early occupation.

Korhonen, Natalia [201] see Tallavaara, Miikka

Kornegay Dollar, Lauren [104]  Evaluating Chronologies of Nasca Trophy Head Iconography
In Nasca archaeology, ceramic iconography contains within it the basic communication lines between the elite and non-elite. Understanding the iconography of this culture carries with it the potential to comprehend the Nasca mindset. The trophy head is a prolific motif in Nasca ceramics. Thus, understanding trophy head iconography is key to understanding the Nasca. Donald Proulx (2006) suggests that Nasca iconography changes over time in conjunction with culture and political influences. He suggests that Monumental Phase (A.D. 1-450) trophy heads will be naturalistic and commonly found in scenes with agricultural motifs. After the fall of Cahuachi, during the Transitional Phase (A.D. 450-550), trophy heads become greater in number per vessel and shift toward more warlike imagery. Proliferous Phase (A.D. 550-750) trophy head motifs become more abstract, but continue to be found with violent themes. I am building upon Proulx's work using data gathered from the collections of the National Museum of the American Indian and the Putnam Museum. My sample follows the patterns proposed by Proulx. I found an increase in trophy heads per vessel during the Transitional Phase. Additionally, trophy head motifs become more violent over time. Potential culture influences for these shifts will be discussed.

Kornfeld, Marcel [284] see Larson, Mary Lou

Korpisaari, Antti (University of Helsinki, Finland) [203]  New Data on the Nature and Date of Tiwanaku Influence in the Azapa Valley, North Chile
Tiwanku-affiliated artifacts are found over large parts of the territory of present-day North Chile. According to the traditional cultural chronology, strong altiplano/Tiwanku influence in the coastal Azapa Valley would have begun in the so-called Cabuza phase (dated earlier to A.D. 300-700, and more recently to A.D. 500-1225), and would have continued in the so-called Maytas-Chiribaya phase. A recent restudy of the burial goods recovered in a total of 470 tombs at the Azapa Valley cemetery sites AZ-6, AZ-71a, AZ-141, and AZ-143 revealed very few Tiwanaku imports at the three first-mentioned sites, and, as has already been noted by Goldstein (1996, 2005), a stronger Tiwanaku presence at the small AZ-143 site. Sixteen new radiocarbon dates from the four cemeteries support the arguments advanced by Cassman (1997) and Sutter (2005), according to which the undeniable Tiwanaku influence seen in Cabuza pottery may have had much more to do with migratory processes set in motion by the collapse of the Tiwanaku state, than with any Tiwanaku-state-controlled attempt to colonize and/or indirectly control the Azapa Valley during the Middle Horizon.

Kosakowsky, Laura [31] see Bauer, Jeremy

Kosakowsky, Laura (University of Arizona) [277]  All Sacbes Lead to Las Cuevas: The Late Classic Ceramics
The ceramics from three seasons of excavations on the surface and in the cave of Las Cuevas have provided a tantalizing picture of this site during the Late Classic (A.D. 700-900). The analysis identified site-specific ceramic complexes utilizing standard types, varieties, and modes, and most importantly ceramic spheres to understand the chronological history of the occupational sequence of Las Cuevas, as well as broader inter-site and regional connections. Las Cuevas appears to have a relatively short occupation, constructed entirely during the Late Classic, with only hints of earlier ceramics in mixed contexts. Although there is a short 200-year construction history, the ceramics exhibit inter-regional connections with the Belize Valley and Vaca Plateau to the north, with sites further south in the Toledo
District and the Xibun, and southeast along the Belize coast. Despite sitting only 14 km from the large polity of Caracol, there is less Petén ceramic influence than one might expect. This intersection of different ceramic spheres centered on Las Cuevas, a relatively minor center that sits above a large and likely important cave, suggests that the site may have sat at a crossroads, serving as a locus for ritual activities and pilgrimages during the Late Classic.

Kosiba, Steve (University of Alabama)

[121] By this Standard: Materiality and Social Difference in the Inka Heartland

In both their myths and rituals, the Inka declared that the Cusco region was the embodiment of their divine mandate to civilize and order the Andes. But how did this region, which was undoubtedly invested with local and pre-Inka cultural understandings, come to be naturalized as inherently Inka? This paper critically evaluates archaeological and art historical theories that seek to explain how standard materials, measures, and styles assembled a coherent aesthetic of Inka authority throughout the Cusco region. Such theories—and the idealized standardization of people and period that they project—often obscure our vision of the actual political work through which state authority is built. The paper presents recent architectural, archaeometric, and ethnohistorical data from Ollantaytambo, a monumental Inka city in the Cusco region, to discuss how the production and distribution of material culture (houses, serving vessels, carved boulders) naturalized the social boundaries and distinctions that undergirded Inka authority. Contrasting traditional archaeological accounts of standardization, the paper argues that the appearance of aesthetic coherence throughout the Cusco region was rooted in the materiality of social difference—the array of materials, practices, and techniques through which people built Inka objects and, in so doing, defined themselves as Inka subjects.

Kosyk, Katrina

[153] A Prelude: Aerophones from Precolumbian Greater Nicoya

Music Archaeology is a relatively new subfield that has not been fully applied in pre-Columbian southern Central America. This is unfortunate because it can offer a truly unique perspective on traditional ideas regarding cultural relations in the past. Archaeologists are now piecing together, at an accelerated rate, the culture history of this region, yet the study of musical instruments remains largely limited to outdated reports from the late 19th century. Developing from recent research based on both archaeological and museum collections, this presentation examines—from a music archaeology perspective—a variety of highly decorated and culturally imbued ceramic ocarinas, whistles, and flutes. Through discussion of iconography, chronological variation, and the spatial distribution of aerophones from Greater Nicoya, including a comparative overview of instruments from surrounding archaeological regions, I offer a prelude to what might be accomplished by integrating the focused study of music with mainstream archaeology.

Kotegawa, Hirokazu (Universidad Veracruzana)

[204] La vida de los monumentos escultóricos olmecas

De acuerdo con los estudios previos, sabemos que hubo una etapa de "reciclaje" o reproducción en la vida de algunos monumentos escultóricos olmecas. Antes de esta etapa tuvieron otras etapas como de la producción y exhibición (o función), pasando la etapa de "reciclaje" otra vez tuvieron la etapa de la exhibición. Arqueológicamente tenemos evidencias de estas etapas. Sin embargo, mayor evidencia solo se encuentra en los sitios grandes como San Lorenzo y La Venta por su taller o la forma mutilada o decapitada de los monumentos para el "reciclaje". También tenemos una perspectiva sobre la estrategia política e ideológica con los monumentos olmecas como una manifestación del poder por la elite. Según esta perspectiva, los monumentos olmecas se distribuyeron dentro de una sociedad jerarquizada por líderes de los capitales San Lorenzo y La Venta. ¿Todos monumentos escultóricos olmecas tuvieron mismo proceso de la vida dentro de una sociedad jerarquizada? En esta presentación examinare los monumentos olmecas de la costa sur del Golfo de Mexico en distintos sitios para llegar alguna interpretación o propuesta sobre esta interrogación. Esta investigación nos dara otra perspectiva del uso de los monumentos olmecas.

Kovacevich, Brigitte (Southern Methodist University)

[330] The Value of Labor: How the Production Process Added Value to Pre-Columbian Maya Jade
Ethnohistoric, ethnographic, and experimental studies demonstrate that the production of jade objects can take years to complete. Studies also show that jade objects were produced by both ancient Maya commoners and elites, suggesting that there may have been a long sequence of production steps and some objects may have moved through multiple producers before completion. It was just this type of arduous process and investment of labor that helped to imbue these objects with value and make them highly esteemed. I will argue in this paper that while some jades may have been restricted to circulation by the elite of Classic-period Maya society, the production process was constitutive of social identity for all status levels.

Kowalewski, Stephen (University of Georgia) and Ron Spores (Emeritus Professor, Vanderbilt)

[83] The Mixtec Kings and Their People

Thesis: The Mixteca was ruled by powerful, hereditary Lords and Ladies who founded towns, owned the land, headed and administered the state, resolved disputes, collected tribute in labor and in kind, went to war, built alliances, engaged in long-distance trade, and carried out ceremonies essential to society. The evidence is in the extensive documentation of the Colonial period, in códices and lienzos, and in archaeological remains of architecture and other material culture at the capitals of the kingdoms.

Antithesis: The real power rested in the hands of the people organized in local corporate groups—the siqui or sindi (barrios) and communities that controlled smallholder rights to land and water, and assured the long-term management and fertility of the landscape, which was the basis of the economy. The evidence lies in the disjunction between the great mass of the archaeological record compared to the small yuhuitayu apparatus.

Synthesis: Both positions are over-idealized. Fixed types (Asiatic autocrats, theater states) do not capture the variation in real cases over space and time. Mixteca history exhibits a contested dynamic between monarchical (autocratic) and popular (communal) forces, a dialectic that continued through the Colonial period and still goes on today.

Kowalski, Jeff (School of Art, Northern Illinois University)

[130] Creation, Renewal Ritual, and Political Authority: Messages in the Mosaic Facades of the Nunnery Quadrangle at Uxmal

This talk examines the Nunnery Quadrangle at the Maya site of Uxmal in the context of that city's rise as a regional capital during the Terminal Classic period, considering possible uses of the building group, the meanings of a selection of individual iconographic motifs, and the broader ideological significance of the complex. The quadrangle’s architectural sculptural program interweaves references to the time and space of creation, ancestral sources of political authority, and more contemporaneous ritual performances, historical events, and tribute wealth. Motifs associated with originary events include the Feathered Serpents and Pawahutun figures on the West Building. Other façade motifs of more current, though not necessarily more secular, historical events, including ceremonies involving the display of captives, and their implied torture and the performance of a type of torch sacrifice in connection with rituals of accession and/or cyclical renewal of time and agricultural fertility. Such iconography, combined with the quadrangle’s monumental scale, superlative stonework, and restricted access, demonstrate that the quadrangle was designed to identify Uxmal as a central place and paramount political capital where the exalted social status of its king, Chan Chahk K’ak’nal Ajaw, and other members of the elite, was affirmed through imagery and social practice.

[173] Late Holocene Land Use in the Middle Susitna River Valley, Alaska

While ethnographies have documented and preserved essential aspects of the past 150 years of Middle Susitna valley Athapaskan culture, archaeologists have an incomplete understanding of the social and economic evolution of societies in the Middle Susitna valley (12,500-150 years ago). This is surprising
considering the major cultural shifts that occurred during these periods, primarily the transition from
highly mobile big game hunting to intensive salmon processing and storage economies, semi-sedentary
villages, and an overall increase in social complexity. Numerous sites containing small and large cache
features and semi-subterranean house structures occur through the Middle Susitna Region of Alaska, but
largely remain undated. Through the investigations of Chunilna Village (TAL-100 and TAL-101) and
Trapper Creek Overlook (TAL-092) as well as testing of previously uninvestigated sites, we have begun
to refine the Middle Susitna valley cultural chronology. Future work in this region should clarify when
salmon harvesting and subterranean fish caching economies first emerged in southcentral Alaska.

[45] Lithic Landscapes in the Mojave Desert
This poster explores lithic procurement strategies in the Mojave Desert in southeastern California. The
project area is located at Fort Irwin and the National Training Center. Recently Statistical Research, Inc.
surveyed 10,000 acres on the installation and identified several large lithic procurement sites, some
covering several square kilometers. The sites consist of thousands of pieces of lithic debitage, and
hundreds of cores, tested cobbles, and hammer stones. This poster looks at how the lithic resources at
these procurement sites were utilized by prehistoric inhabitants of the Mojave, and how the sites fit into
the wider settlement pattern system of the region.

Kretzler, Ian (University of Washington) and Ben Marwick (University of Washington)
[214] Understanding Archaeological History through Textual Macroanalysis: The Role of Feminism in
Gender Research
Over the past three decades, gender research in archaeology has spurred investigations of gender
relations in prehistory and problematized androcentric interpretations of the archaeological record.
Though much of this work draws heavily from feminist theory, some archaeologists argue for increased
separation between feminism and the study of gender. Existing quantitative studies suggest
archaeologists share this latter view. In order to develop a more complete understanding of the
relationship between gender research and feminism in archaeology through time, we used textual
macroanalysis to track the frequencies of and correlations between key words in more than 3000 articles
published in American Antiquity over the past three decades. In doing so, we constructed a history of
gender research in archaeology and evaluated the role of feminism in it. Our results suggest that while
explicit contextualization in feminist theory is often lacking in archaeologists’ investigations of gender,
their engagement with feminism has been underestimated. This research not only complicates traditional
narratives regarding archaeology and feminism, it highlights the worth of textual macroanalysis in
developing quantitative histories of archaeology that reflect the work of archaeologists broadly rather than
a select group of theorists.

[12] Weeden Island Paleodiet and Mobility: Isotopic Results from Three Coastal Sites in Northern Florida

'Weeden Island' is a Woodland period complex in eastern North America traditionally defined as a pan-regional religion or interaction sphere. Akin to Midwestern Hopewell, Weeden Island united disparate communities in common ritual practices across a large region. While material culture, settlement patterns, and subsistence regimes were highly variable across Florida and southern Georgia between ca. A.D. 200 to 750 many attributes of burial mound ceremonialism appear strikingly uniform. Still poorly understood are patterns of mobility and social interaction that may have promoted equivalencies in mortuary practices.

This research explores the Weeden Island phenomenon as it relates to human mobility by integrating multiple lines of isotopic data from three Middle Woodland skeletal populations [Ross Hammock Mound 1 (8VO131), Hughes Island Mound (8DI45), Mayport Mound (8DU96)]. The three sites are coastal maritime in context and each is characterized by distinctive geology with unique isotopic signatures. Preliminary results underscore the potential to clarify intrasite and intersite trends in diet and provenience. For example, carbon, oxygen and strontium isotope ratios derived from human tooth enamel identify clearly non-local 'outliers'. Our approach complements concurrent analysis of artifact assemblages in that the data reflect a single individual with a unique life history and sociocultural fate.

[37] The Frame and the Fold: Spatiality in the Group of the Thousand Columns, Chichén Itzá

Coming to terms with ancient spaces is not a straightforward exercise. Conceptions of margins, scale, aesthetics, inside/outside, and other concerns vary widely through across time and distance. Ethnohistory and ethnography can fill in some lacunae of knowledge, yet traditional media of spatial analysis—primarily photographs and reconstructions—replicate spaces as static and cubic. The Group of the Thousand Columns at the late Maya site of Chichén Itzá, Yucatan, exemplifies how a space has been understood as stationary and mute. Several types of borders, including fences, causeways, and colonnades, enframed and sequestered this elite precinct of palaces, ballcourts, temples, and distinctive sculpture in the site core. The ideas of philosopher Giles Deleuze can help transform the idea of buildings from geometric to folded, accordion-like structures that affect and respond to people and activity. Deleuzian folds offer several advantages in the interrogation of space: they approximate hubs and paths of activity; they are practical and perceptive explanatory models; and they to enrich an understanding of ancient spaces where so often the focus is on architectural or iconographic details that the big picture of society is overlooked.

[44] Shell Exchange and Interaction in the New Mexico Borderlands: Assemblage Diversity and Network Analysis Approaches

Previous studies of shell exchange in the Greater Southwest have supported archaeological interpretations of competing exchange networks in which the Hohokam, Sinagua, and Anasazi acquired shell from the Gulf of California, while the Casas Grandes, Mimbres, and Western Puebloan groups acquired shell from West Mexico. Notably, these studies found that Animas phase sites, including Joyce Well, clustered with the Casas Grandes shell network. In this study, we attempt to further studies of economic interaction in the borderlands region by comparing the shell assemblage from the 76 Draw Site, a large Animas phase site located near Deming, New Mexico, with several published Southwestern and West Mexican datasets. Comparing the results of shell morphology and assemblage diversities with the results of a network analysis, following a least-cost pathway model, allows us to further test hypotheses about potential shell trade routes into the Greater Southwest.

[13] A Little Bit Longer: The Date of Events at the SunWatch Site

Twenty-one radiocarbon results from houses, pits, and burials at SunWatch are presented with an interpretative Bayesian statistical framework. Three different archaeological interpretations for site chronology are given in separate Bayesian models. In our preferred model there is a building sequence for seven structures and a central post, identified in Cook (2007), and the remaining structures and pits are placed outside of this sequence. In the Bayesian model for this interpretation, occupation begins between cal. A.D. 1045-1235 and reoccupations occurred at SunWatch until cal. A.D. 1420-1520. An alternative model without the central post-structure sequence was created and produced very similar results. A second alternative model did not produce valid results and it is highly unlikely that the short-term occupation scenario occurred. Results are further reviewed in relation to the occupation sequence and nature of settlement. We conclude that multiple occupations likely occurred at SunWatch over a 210-445 year timespan and that multi-generational remembrance is reflected in the patterned positioning of structures, pits, and the central post.

[102] Modified Preservation Index for Skeletal Remains: Case Study from the Medieval Cemetery at the Church of Saint Mari Magdaleny in Pilsen, Czech Republic

Understanding the preservation of human skeletal remains is an important step toward interpreting the archaeological record. Various methods exist to characterize the degree of skeletal preservation. This paper presents a new Modified Preservation Index (MPI), which is an extension of the Preservation Index (PI) of Stojanowski et al. (2002). PI is a quantitative evaluation of 80 skeletal elements that are commonly used in anthropological analysis. MPI introduces additional criteria (178 elements) used in new methods for estimating age, sex, and height from skeletons. MPI adjusts for partial recovery of skeletons that may occur during emergency excavations. The main differences between the methods are that MPI is suitable for analysis of individuals from all age categories, and MPI is typically greater than PI due to adjustments for the conditions of archaeological research. The PI/MPI methods were applied to a sample of 217 skeletons from a Medieval cemetery in Pilsen, Czech Republic. The PI/MPI data were tested for correlations with intrinsic factors (age, sex) and extrinsic factors (stratigraphic level, distance from the church, presence/absence of an anthropologist during excavation). Preservation state was significantly
correlated with age category, and with the presence/absence of an anthropologist.

Kuckelman, Kristin (Crow Canyon Archaeological Center)
[344]  A Room with a View: New Data on Uses of Multistory Structures in Late Pueblo III Villages of the Northern San Juan
The ancestral Pueblo multistory structures of the northern San Juan region, also referred to as "towers," have inspired many theories regarding their purpose and use: astronomical observation, defense, storage of crops, storage of ritual paraphernalia, lookout, domestic activities, or as visual symbols of power. However, even after more than 100 years of excavation in the region, interpretations have suffered from a paucity of empirical data. Recent research by the Crow Canyon Archaeological Center at the thirteenth-century, large village site of Goodman Point Pueblo in southwestern Colorado generated a substantial body of data through excavations in 11 multistory structures. Some such structures were located in residential roomblocks, others were associated with ritual, integrative, or special-use structures such as a great kiva or D-shaped bi-wall building. The resulting data do not suggest the storage of food or ritual paraphernalia but do indicate use as living and work space, storage space for vessels, tools, and other durable goods, and defensive use. Two isolated single-story structures thought to be towers proved to be kivas. These new findings add to the body of knowledge on the organization and use of secular and ritual constructed space in late Pueblo III settlements in the northern San Juan.

Kuhn, Steven (University of Arizona)
Recent research shows that step lengths for movements of individual human and non-human foragers tend to assume a limited range of distributions. In many cases the step-lengths form a highly right-skewed Lévy distribution, with many short movements and a few very long ones. In other cases, analogous to Brownian motion, distributions are more Gaussian. Both human and animal foragers have been observed to use different movement strategies according the distribution of prey and levels knowledge they possess. This raises the question of whether path-length distributions emerge from an interaction between resource distributions and very simple search rules, or whether they require specific behavioral or cognitive control on the part of the forager. Agent-based models are used to investigate whether Levy flights and other movement patterns can arise as a consequence of the application of a single set of search rules to different resource distribution. Changing resource patchiness does affect step length distributions, and some distributions are strongly right-skewed, but they are not in fact fat-tailed Lévy flights. These particular movement patterns do not emerge easily from most combinations of resource patchiness and decision rules, but require some other controlling factor.

The concept of Improvement cross cuts moral, cultural and ideology realms, as well as practical aspects of material life, including housing, education, and agricultural technology. Tracking tangible and measurable material change allows researchers to link past ideas and processes to actions, and action to material remains. Archaeological and historical research on Inishark, Co. Galway, Ireland, provides a unique opportunity to identify and interpret the material footprint of Improvement from the 1880’s to the 1920’s. Improvements on Inishrk were linked to the development of Irish national policies, changes in landholding systems, and the sale of land and houses by the Congested Districts Board.

[203] Of Mines and Men: Reverberations of Wari Investment in Andahuaylas

How did imperial industries impact laboring subjects in the ancient Andes? This study investigates skeletal and artifactual data excavated from a prosperous salt and copper mining village in western Andahuaylas (Apurimac), to illustrate how Wari-directed ore extraction and processing structured the lives (and deaths) of local people during the later Middle Horizon. Over 200 crania from different village sectors were evaluated to reconstruct demographic, health, and mobility profiles using standard methods. Results demonstrate the multivalent ways in which Wari’s imperial incursion irrevocably altered local group interactions and mortuary traditions. Far from ephemeral, some of these practices were maintained long after the archaic empire’s fragmentation, and laid the ground work for future regional competition and conflict.

[302] The End of Political Authority at Callar Creek, Belize

Politically authoritative relationships are prominent and persistent features of ancient, other, and our own lives. Such relationships, however, are ephemeral rather than perpetual, transient rather than permanent. Fully understanding the operation of political authority thus necessitates understanding the processes by which authority breaks down and is rejected, challenged, or made untenable. This paper will examine the end of political authority at one specific community: the low-level ancient Maya center of Callar Creek, located in the Mopan Valley of Belize. Recent investigations by the Mopan Valley Archaeology Project suggest that the cessation of politically authoritative relationships at the site was marked by the purposeful razing of architecture, burning of structures, and smashing of ceramic vessels and other objects – by a termination event. This paper will describe the termination event; argue that it plausibly represents an attack by outsiders on Callar Creek’s central structure; and conclude that politically authoritative relationships at Callar Creek were challenged, and ultimately negated, by those living outside the site core.

Kvamme, Kenneth (UNIVERSITY OF ARKANSAS)

Michael Jochim’s 1976 book Hunter-Gatherer Subsistence and Settlement: A Predictive Model was a ground-breaking work from several stand-points. It advanced hunter-gatherer studies through a worldwide ethnographic synthesis of settlement, subsistence, and demographic behaviors and it advanced knowledge of the south German Mesolithic, but most of all it established a methodological perspective that prehistoric settlement locations could be modeled. Although it did so without reliance on GIS technology (preceding it by nearly a decade), in my view this work served as a launch point for the subsequent development of GIS-based archaeological location models. Since the 1980s these models, known more simply as "predictive models," have achieved much attention and they have been widely used for cultural resource management purposes, representing a multi-million dollar worldwide industry. Most models are based on statistical patterns of location summarized from known archaeological distributions, which are then mapped through a region by GIS to form location predictions for as-yet undiscovered archaeological sites. Almost from their inception these approaches have received criticism for their lack of a "deductive" methodology that considers past rules and behaviors that formed settlement
choices. Yet, Jochim's pioneering work actually serves as a rare example of a deductive model.

[299] Pathway to the Neolithic: augmented reality and the virtual museum

The aim of the poster is to present an ongoing project devoted to the virtual museum of the Neolithic. Two main methods have been used in the project: 1) 3D optical scanning technology that exactly reflects the 3D surface geometry of the artefacts and will bring new presentation possibilities, 2) virtual reconstruction of Neolithic landscape and cultural structures it included. Although introduction into the general Neolithic agro-pastoral culture will be provided, detailed examples will be based on case study of the Central European Neolithic settlement in Bylany (Czech Republic), dating from the 5th - 6th millennium B.C. The purpose of the project is not only to present the Neolithic in the virtual space but also to show people how deeply rooted is the past in the real landscape. To solve the obvious problem that in today landscape nothing from the Neolithic is preserved on the ground, we are trying to follow the technology of augmented reality. This concept uses integrating GIS map with the virtual reconstructions of Neolithic village and the open library of 3D scans. Either in the computer or in real landscape the visitor will be able to overstep the threshold of the present.

[24] The Slim Arrow site, a late Paleoindian bison kill in the dune fields of Yuma County, Colorado

Slim Arrow is a late Paleoindian bison kill located in the Wray dune field, in the uplands between the Arikaree and Republican Rivers of Yuma County, Colorado. Discovered and surface collected by the Andersen family in the late 1920s, the site contains a minimum of 65 projectile points (mostly Allen complex forms), 12 scrapers, 6 other tools, and debitage. Richard Snodgrass (American Museum of Natural History) completed limited work there in the early 1930s, but the site remained nearly unknown until relocated and tested in the early 2000s. At Slim Arrow, Paleoindian hunters geared up in western Kansas before heading up stream for bison hunting on the High Plains grassland. The large quantity of weaponry, as well as a linear concentration of bone, suggests a kill similar to the Olsen-Chubbuck site (140 km south). This presentation is dedicated to the memory of Joe Cramer and Jim Benedict, both of which gave substantial gifts towards the archaeological research of the ancient peoples and environments of North America.

A Tale of Shape: Refining Our Understanding of Past Plant Use through Phytolith Morphometrics and Multivariate Statistical Analyses

Questions regarding past plant use are crucial in the meaningful interpretation of archaeological sites. What people ate, how food was prepared, where the plants came from, the contexts of consumption, and a myriad of other questions can be answered via analysis of the paleoethnobotanical record. Phytolith analysis has been at the forefront of the employment of new techniques and morphometric studies, in particular, have increased the accuracy of plant identification and refined the taxonomic resolution possible. Recognizing that different varieties of the same species were grown at archaeological sites sheds light on the movement, interaction, and preferences of past peoples. In order to gain this fine-scale information, however, the method and theory behind phytolith morphometrics and multivariate statistical analyses must be understood. This poster provides a thorough explanation of the mechanisms involved in obtaining and interpreting these data. Special attention is given to how the researcher decides to include or exclude certain morphometric measures, what these measures mean, and how to select and correctly interpret the multivariate analyses applied to these data. The results of the application of these techniques to the American Southwest in the context of maize cob analysis are presented as a case study.

Empires Crafted of Clay: Earthenware Archaeometrics and the Characterization of Gendered, Multi-Scalar Political Expressions of Middle Horizon Andean Earthenware Vessels.

Patterns of polygynous social organization and gendered political affiliation are discernible when archaeometric data, earthenware form, and iconographic evidence are considered. Iconographic details from over 400 earthenware vessels and sherd materials from the contemporaneous Middle Horizon (MH) empires of the Wari and the Tiwanaku (ca. 600-1100 C.E.) are included in this preliminary examination. Archaeometric and archaeological data are juxtaposed with ethnographic and ethnohistoric scholarship to evaluate the impetus that lay behind the production of these hybrid-political expressions. Wari earthenware hybridity is attributed to multi-scalar political alliances made manifest through affinal relationships, whereas iconographic heterogeneity is associated with mosaics of meaning linked to women’s identity, expressions of ethnicity and alterity, “secret” sacred knowledge, and intent to imbue vessels with mana.

I suggest that “foreign” women were integrated into both Wari and Tiwanaku society and actively contributed to the formation and reproduction of the overarching sociopolitical framework via symbols displayed on highly-visible earthenwares utilized during large-scale sociopolitical events. Additionally, women skilled in the production of earthenwares and chicha could attain a relatively higher status, for it was the distribution of these goods formed the cornerstone of the chicha-based economy that sustained these MH Andean states.

A Non-Destructive Method for Dating Human Remains

In 1973, the skeletal remains of several Native Americans were recovered from a creek bank in northeastern New Mexico. The remains became lost amid the collections of a local museum for 36 years. In an effort to repatriate the remains, it was necessary to fit them into a regional cultural chronology in order to determine the appropriate tribe(s) for consultation pursuant to the Native American Graves Protection and Repatriation Act. Because the remains were found in an eroded context with no artifacts or funerary objects, their age was unknown. Wishing to avoid destructive dating methods such as
radiocarbon dating, Optically Stimulated Luminescence (OSL) was used to date the sediments that had become embedded in a cranium. The OSL analysis, conducted at the USGS Luminescence Dating Laboratory in Denver, Colorado, yielded dates between A.D. 920 and 1455. We conclude that the remains were interred somewhat earlier than A.D. 920, but no later than A.D. 1455, and the appropriate Native American tribes are being contacted for the repatriation efforts. Not only do our methods contribute to immediate repatriation efforts, they provide archaeologists an established, versatile, and non-destructive absolute dating technique that can be used in many burial contexts.

Reconsidering Western Apache Problems and Approaches

In 1981 David Gregory described the problems and approaches to Western Apache archaeology. Since this first synthesis of the subject, recognition and documentation of Western Apache sites, features and artifacts has increased significantly, and the interpretation has relied heavily upon comparison with historical-period accounts and reference to ethnographic works of Grenville Goodwin, Keith Basso and others. In this paper, we provide a status report on what has been learned over 32 years of survey recording and excavation, and look forward to opportunities contained in this ever-growing and evolving set of information concerning Apache history and culture. Moreover, more meaningful interpretation of the past will come from working collaboratively with Apache cultural experts to ensure archaeological and anthropological projects in reference to contemporary and ancestral Apache land base concerns, issues of importance to Apache people today and in the future.

Interpreting Workshop Food Supply from Faunal Assemblages and the Production Organization of Iron Industry during the Han Era: An Example from Taicheng Iron Foundry

Animal bone assemblages from an iron foundry in the Guangzhong basin, the heartland of the Western Han dynasty, are analyzed in a comparative framework to interpret aspects of food systems and organization of Han Iron Industry. Characteristics of the nature of food supply are interpreted from taxonomic representation, body part representation, butchery patterns, and age patterns. These analyses show that the foundry relied heavily on specialized husbandry and might have obtained food through a marketplace system. The discovery seems to be supportive to the exploration according to other aspects of data that the foundry was a centralized workshop specialized in the production of commodity goods. A model that explores the relation between patterning of bone collections and production organization is applicable to other studies of craft specialization.

Current Explorations of the Formative-Classic Maya Hinterlands of Ucí

Over several field seasons, members of the PASUC surveyed a 4 km² block whose center point lies 4km to the east of Ucí. The survey, which attempted to understand Ucí's hinterlands, documented a landscape of several small settlement clusters separated by tracts of minimally constructed land. Excavations and mapping revealed variability in the occupants' wealth, economic specialization, and integration within larger political economic spheres, underscoring the heterogeneity of these "rural" occupations. Given that an intersite causeway, or sacbé, connecting Ucí to other centers such as Kancab, runs close to these clusters and required major economic and social investment, it could be thought that the rural settlement clusters were "centered" on this feature. Without the existence of a clear civic-ceremonial center in the vicinity of these clusters, present terms and ideas such as "center," "periphery," and even "rural" would need to be reassessed to take account of the settlement patterns documented. In this paper we discuss the settlement composition near and around the sacbé, exploring not only the relationship between the different settlement clusters but also the relationship between these clusters and the larger social landscape as materialized by this causeway.

ICP-MS Analysis of Sediment for Sourcing Ceramic Sherds in Shkodër region of Northern
Albania

Inductively-coupled plasma -- mass spectrometry (ICP-MS) was used to determine the elemental composition of sixteen sediment samples collected in the Shkodër region of Northern Albania during the 2012 field season of the Projekti Arkeologjikë i Shkodrës (PASH). These data have been combined with ceramic compositional data, mapped, and analyzed using a geographic information system (GIS). Spatial analysis indicates intra-regional variation in soil chemistry and helps contextualize ceramic distribution patterns and prehistoric and historic settlement location.

[251] Revealing Spiro's Lost Artifacts: The Research Value of WPA Artifact Illustrations from Craig Mound

The Spiro site (A.D. 850 – 1450) in eastern Oklahoma is one of the most important archaeological sites in North America. However, the primary focus of archaeological research on the site has been the mounds themselves and their associated artifacts. I will show that archaeologists can generate valuable new finds about Spiro from archival research. The Sam Noble Oklahoma Museum of Natural History in Norman, Oklahoma, holds hundreds of unstudied Work Projects Administration (WPA) illustrations that depict artifacts from Craig Mound, the largest mound at Spiro. Study of these WPA drawings has revealed that several of them represent artifacts that have not been seen since their initial discovery in the 1940s. I suggest that these newly discovered illustrations would expand our knowledge of Spiro’s deep prehistory. In particular, the illustrations will foster new inferences into Spiro iconography, give back contextual knowledge of the lost artifacts, help authenticate objects that are currently in public and private domains, and provide more comparative imagery that expands continuing analyses of iconography in the Southeast.

Lambert, Patricia (Utah State University)
[306] Bodies of Evidence: The Meaning of Sex Differences in the Location of Violent Injuries

Depressed cranial vault fractures and injuries from projectile or thrusting weapons are two types of violent trauma recorded with some frequency in Native American skeletal remains from California. The cranial injuries are most commonly healed, and thus indicative of some form of sublethal conflict, whereas the projectile injuries are more often unhealed or by location indicative of lethal intent. These injuries thus reflect at least two quite distinct forms of interpersonal violence, one meant to injure, the other to kill. What is particularly interesting from a biocultural perspective is that when the location of these injuries within the body is examined according to the sex of the victims, some notable differences emerge. These differences suggest both distinct contexts for how violent injuries were incurred, as well as differences in how the bodies of men and women were targeted by assailants—even in what was likely the same context (e.g., raid). This paper examines these sex differences in wound location and explores possible contexts and causes for this gendered variation in violent trauma.

Lambert, John (UC Davis) and Thomas Loebel (St. Xavier University)
[315] Cody way out East: Late Paleoindian Mobility in Early Postglacial Wisconsin

Cody complex lithic assemblages from northern Wisconsin support the assertion that the first hunter-gather populations to colonize this early postglacial landscape were highly mobile. The distribution of specific lithic raw materials implies that these late Paleoindian groups exploited an area extending from northeast Minnesota to central Wisconsin. Analysis of collections from the Forks View site in Calumet Co., WI helps elucidate the behavior of groups at the southern end of this range. When combined with material from other nearby surface collections, the Forks View assemblage provides a robust sample with both early (Clovis, Folsom/Midland) and late Paleoindian components (Cody, Agate Basin, Dalton, Alberta, Hell Gap), as well as younger Archaic and Woodland material. Documenting these lithic assemblages is a crucial step toward answering questions about diachronic changes in hunter-gatherer mobility before and after the entrance of Cody complex foragers into the region. The Paleoindian/Archaic transition marks a dramatic shift in residential mobility and toolstone utilization. Paleoindian assemblages in the sample are dominated by exotic, high quality raw materials, average transport distances routinely exceed 200 km, and toolkit composition reflects a reliance on long-distance residential movement. In contrast, Archaic and Woodland assemblages are composed almost entirely of local raw materials.

Lambert-Law De Lauriston, Timothy (The University of the Witwatersrand)
An Exploration of Use-Wear Analysis on Acheulean Large Cutting Tools: The Cave of Hearths’ Bed 3 Assemblage

Large cutting tools (LCTs) are a stone tool technogroup that appeared ~1.76 Ma in Africa and marked the beginning of the Acheulean. The group is comprised of three tool "types" called handaxes, cleavers, and picks. The function of LCTs has only been arrived at through assumption or through experimental tasks designed to determine if a tool "type" was efficient for a given task, e.g., are handaxes conducive to butchery tasks? To date, no extensive use-wear analysis has been carried out on African Acheulean LCTs and this is a pioneering study. The Cave of Hearths lies in the Makapan Valley in the Limpopo Province of South Africa. Excavations were carried out from 1947 to 1954, and it is from these excavations that this study draws its sample. Use-wear analysis can shed light on why the Bed 3 assemblage, and indeed the whole Acheulean assemblage, is dominated by cleavers. In addition, the data generated by this study can be used to understand other areas of archaeological inquiry such as early subsistence patterns, dietary trends, site use, etc. It will also provide the foundation needed for future studies to be carried out on LCTs from other sites in Africa.

Catholic Mortuary Practices of the Fifteenth to Eighteenth Century: A Comparison between Tayasal, Peten, Guatemala and the Iberian Peninsula.

Excavation of various necropolises distributed across the Iberian Peninsula during the Middle Ages to the Renaissance indicate the presence of Catholic, Islamic and Jewish modes of mortuary practice. Canons of Catholic mortuary practice prescribed that burial grounds be associated with religious temples within urban centers. Graves, oriented west-east, were expected to contain individual inhumations without associated grave goods. Individuals were typically inhumed extended on their backs with the head oriented towards the west. This positioning allowed the deceased to face east, the sacred direction of Heaven. The arms of the deceased were placed in a semi-flexed configuration with hands over the pelvic, abdominal or chest region. Between the thirteenth to eighteenth century Spain and Portugal were two of the strongest economic powers of Europe controlling different areas of the Americas, Africa, Asia and Oceania. Examination of inhumations beneath the church of the San Bernabé mission located at Tayasal, Petén, Guatemala, revealed mortuary practices homologous to those described in the Iberian Peninsula during the fifteenth to eighteenth centuries. These similarities serve to demonstrate a process of assimilation of Catholic canons of mortuary practice by local populations of the Tayasal region.

Lamoureux St-Hilaire, Maxime (Tulane University) and Evan A. Parker (Tulane University)

A Behavioral-Contextual Approach to On-Floor Assemblages

The best archaeological correlate for the Classic Maya collapse – settlement abandonment – is sometimes recognizable in the very last occupation of structures or in "on-floor artifactual assemblages." Unfortunately, the taxonomy for abandonment-related assemblages varies widely among scholars, ranging from 'problematical deposits' or 'de-facto refuse', to "termination caches". This paper proposes a methodical approach to on-floor assemblages based on site-formation processes theory, and is anchored in a highly contextual approach. This behavioral-contextual approach examines the vertical and horizontal architectural context of artifacts, the relative completeness of ceramic vessels, and the represented vessel forms in order to produce quantitative and qualitative data that may be complemented by multivariate statistical analyses. The resulting interpretive framework allows for distinct settlement abandonment scenarios to be reconstructed in a systematic, replicable fashion while using a specific contextual terminology. This methodology accounts for rapid and gradual abandonment, abandonment with anticipated return, mundane and ritual abandonment practices, and post-abandonment behaviors, all which correspond to various socio-political contexts and differential human resilience to a host of challenges. Case studies from the sites of Minanha, Belize, La Corona, Guatemala, and Escalera al Cielo, Yucatan – all abandoned in distinct fashions – illustrate the operation of this methodological approach.

Landa, Olga

ANALISIS ARQUITECTONICO DEL EDIFICIO M DE MONTE ALBAN

Por análisis arquitectónico se entiende la distinción y separación de las partes de un todo hasta llegar a conocer sus principios o elementos, presentaremos un análisis del edificio M de Monte Albán. Fue investigado a partir de los años 30 y restaurado a lo largo de varias décadas con estas investigaciones se ha llegado a conocer las características formales de la estructura. Revisamos los cambios que
sufrió a lo largo de 80 años y hablaremos del tipo de restauración que recientemente se llevó a cabo para conocer de manera íntegra su sistema constructivo así como sus características formales, abordaremos de cerca la manera de intervenir la arquitectura monumental así como las ventajas y desventajas de restaurar un elemento en diversas etapas en donde han cambiado los lineamientos de restauración a lo largo de la historia.

Landau, Kristin (Northwestern University), Heather Richards-Rissetto (Middlebury College) and Marc Wolf (CUNY Graduate Center)

Today the use of 3D technologies for architectural visualization, monument conservation, and education and public outreach is not uncommon in the archaeology of the Ancient Americas. However, real time applications of these tools to produce 3D architectural and landscape models that inform ongoing archaeological excavations and subsequent interpretation are few. We present the process and results from an exploratory project that utilized 2D maps, SketchUp models, and LiDAR data to guide field excavations (June-Oct 2013) at an ancient neighborhood on the southern periphery of Copán, Honduras. Specifically, the datasets included: (1) a theodolite/plane table map created in the 1980s, (2) a newer, 2012 total station/GPS map, (3) LiDAR data flown in May 2013 by the MayaArch3D Project, and (4) interpretive, 3D SketchUp models based on the previous three. These datasets are not mutually exclusive, and in fact, build and improve upon each other in combination with on-the-ground “truthing” through archaeological excavation. Tacking back and forth between 2D maps, 3D models, and excavation data provided a corrective for the maps and models, and helped us more efficiently and accurately address archaeological research questions such as internal neighborhood organization and political economy.

Landon, Amanda, Heidi Roberts (HRA, Inc. Conservation Archaeology) and Christopher Harper (HRA, Inc. Conservation Archaeology)

[334] Incised Stones at Post-Puebloan Period Sites in Southern Nevada

Incised stones are rarely recovered from excavated Virgin Branch Ancestral Puebloan sites in Nevada and Utah. Though absent during Puebloan times, they debut in the archaeological record after A.D. 1300, during the habitation shift from surface architecture to rock shelters or open camps. Often, these less permanent habitations contain mixed pottery assemblages with buff wares, gray wares, and Great Basin Brown Ware. Buff wares, which are typically associated with proto-Mojave or Patayan groups, dominate many of these Post-Puebloan assemblages, yet the presence of incised stones hints at connections to the Great Basin region. This paper examines the timing and distribution of incised stones in regions formerly occupied by Virgin Branch Puebloan groups.

Landry, Shannon (Northern Arizona University)

[79] Faunal Identification and Age Assessment through Dental Analysis: The Wetherill Trading Post, Chaco Canyon, NM

Inhabited at the turn of the 20th century, the Wetherill Trading Post illustrates early archaeological activities in the Southwest. Over the past several years, the University of New Mexico has conducted archaeological excavation and research in Chaco Canyon, NM to understand the homesteading lifestyle common to the Southwest. In this poster, I present results on the zooarchaeological analysis of domesticated and game fauna used for subsistence at the homestead. Through the use of historic documentation, photographs, and firsthand accounts in the analysis, I provide a framework for understanding differences in the ratio of game animals versus domesticated animals in the trading post context. Using animal dentition, I determined age and taxon presence at the site. Analyzing the differences between the animals historic records indicate were consumed and actual faunal remains provides valuable insight for historical archaeologists about consumption behaviors.

[332] AROURA: Reconstructing an Extensive Agricultural Landscape around the Late Bronze Age Fortress of Glas, Central Mainland Greece
Between 2010 and 2012, UMBC and 9th Superintendency of Prehistoric and Classical Antiquities carried out an extensive magnetometric survey and surface collection of the plain around the Late Bronze Age III (ca. 1300–1200 B.C.E.) fortress of Glas in the northeastern Kopaic Basin, a karst polje in Viotia Prefecture, Greece. The plain immediately around the fortress consists of an area protected from the wetlands of the Basin by a dike. It was further preserved from inundation by canalization of seasonably variable rivers flowing into the polje, these hydraulic features also generally dated to the LBA. Magnetometry covered over 60 hectares, revealing a network of magnetic anomalies connected with both Glas and the larger hydraulic works. Ground-truthed results showed that the anomalies correspond to features built of ancient lake bottom sediment, sometimes paved with boulders, and perhaps paralleled locally with ditches. The network is consistent with a meticulously planned and executed arrangement of agricultural fields, irrigated from the canalized rivers. Various radiometric analyses indicate these features were constructed at some time between 1880 and 1310 B.C.E.—i.e., in the centuries leading up to Glas’ foundation. Discovery of traces of such a landscape is unique in the Aegean and of signal importance.

Lang, Elizabeth (Yale University)
[127] “Our Daily Bread”: Modeling Day-to-Day Household Food Production and Consumption in Ancient Egypt

Food procurement, preparation, and consumption are universal human requirements, and the processes involved are powerful carriers of identity and ritual information. Such processes are often nearly invisible in the archaeological record, and as a result, investigations utilizing traditional methods have been unable to construct a full picture. This presentation will take a new direction, integrating archaeological, textual, and pictorial data with non-traditional lines of evidence such as ethnographic comparison, experimental archaeology, and anthropological theory. The goal of this presentation is to generate a model for quotidian food procurement, preparation, and consumption in the New Kingdom period of ancient Egypt (ca. 1550-1069 B.C.E.). This model will show that food procurement and processing required huge amounts of time and labor to process raw food into edible, satisfying meals. Such significant investments of time and work, along with commensality within the household, argue that food and the interactions ancient Egyptians had with food were incredibly significant, and necessary for the construction of identity at the household level. This presentation will emphasize an integrative approach to evidence for this important aspect of Egyptian life.

Langenwalter, Paul (Biola University, La Mirada, CA)
[163] Assessing the Evidence for the Ritual Burial of Badgers (Taxidea taxus) in Central California

Early archaeological research in central California revealed evidence of animal oriented ritual in the form of burials. Systematic archaeological research in the 1930s incorporated the idea of animal ceremonialism to explain the occurrence of species of birds, mammals and reptiles in individual burials recovered from sites in the region. Badgers (Taxidea taxus) are among the species reported in ritual burials from several sites. Additional examples have been sporadically reported from the California Culture Area. Recent studies indicate that a lack of rigorous criteria for feature identification resulted in the inclusion of a number of naturally occurring, burrowing dead animals, as examples of intentional ritual burials. Criteria are needed to identify intentional burial of badgers because they may be incorporated into archaeological contexts through natural processes. Such criteria include documented evidence of burial position, grave excavation vs. burrows, and the presence of grave goods. Radiometric dating of some of badger burials indicate that some features containing badgers are younger than their apparent archaeological contexts imply, further complicating interpretations. All features containing articulated badger skeletons should be dated to verify spatial and temporal associations within the archaeological context where they occur.
Langlie, BrieAnna (Washington University in St. Louis)

[150] Food Fights: Recent Research on Terrace Agriculture in Puno, Peru (A.D. 1100-1450)

Altiplano peoples’ changing use of the landscape during the Peruvian Late Intermediate period (A.D. 1100-1450) is often attributed to widespread warfare in part precipitated by climatic fluctuations. Specifically, people relocated to defensible, but logistically inconvenient, hill-forts to cope with the threat of enemy attack. This move and the environmental instability of the time are often viewed as adversely affecting agricultural production. Some scholars suggest inhabitants abandoned plant agriculture in favor of pastoral strategies. However, this simplistic model does not properly account for the adaptability of altiplano agriculture to a variety of social and environmental conditions. For example, from the vantage of hill-forts, farmers could sustainably grow food on adjacent agricultural terraces. Models derived from the field of political ecology would predict a ramping up of land use strategies during this era through either intensification or extensification. Within this framework, I present data from recent research conducted at Ayawiri, an LIP hill-fort located in the northern Titicaca Basin of southern Peru. In particular, recent excavations of agricultural terraces on the slopes below Ayawiri elicit a more nuanced picture of land use and the deep time adaptability of altiplano agriculture.

[326] Involving Local Communities in Archaeological Projects

The Archaeological Institute of America (AIA), through its Site Preservation Program, works with a diverse array of projects around the world by providing support for heritage conservation and community outreach efforts. Through this program we have been able to observe many different approaches to involving local communities in archaeological projects. The most sustainable and effective programs actively involve and engage local communities from the earliest stages of the project and maintain these relationships beyond its completion. While there is no “one size fits all” way to involve local stakeholders, creative and flexible project directors who take the time to understand the interests and needs of the surrounding communities design robust programs that are incredibly successful and rewarding for everyone involved. In this paper we assemble the collective wisdom gained from more than a dozen projects around the world and present the challenges, outcomes, and the inevitable surprises encountered by these projects.

[205] Peasant Life and Agricultural Practices as Mitigating Factors against Political, Economic and Environmental Stress in Middle and Late Islamic Jordan: The Social Significance of Phytolith Analysis

This paper seeks to inform previous historic and archaeological work about local economies, and seeks to place medieval peasants on the political and economic stage in middle and late Islamic Jordan. Agricultural history is positioned in a diverse landscape of the peripheral Mamluk state in Jordan. Peasantry, imperial agricultural exploitation, and rural history are viewed as interrelated factors affecting and reflecting the political and economic history and the landscape. The role of small rural communities as agricultural producers and consumers and their dependence or not on their immediate urban environment are investigated through the identification of daily agricultural practices and crop processing analysis. Phytoliths (micro-botanical remains) are used as an excellent proxy data in order to reconstruct local agricultural and pastoral pursuits adopted by the peasants. The phytolith data presented and discussed in this paper have been collected from medieval rural sites and their analysis aims to inform the decisions that real people make in order to minimize risk and their ways of adapting to crises. The character of medieval Jordanian rural society and practices are thought to be capable of offering an alternative understanding of the regional history.

LapeyreMontrose, Stephanie (California State University Graduate Student)

[174] Mapping Success: Available Technology and a Multi-Disciplinary Approach Can Improve the Odds of Hominin Site Discoveries
Hominin fossil finds have been a source of scientific discoveries and debates for years, but unfortunately, fossil discoveries are limited. When fossils are found, it is either by chance discovery, such as the case with sites found in quarries where finds are more often than not damaged, or by focused efforts on already known areas likely to contain sites. What if we could use technology to increase our chances and to hone in on unknown areas that are more likely to contain fossil bearing zones prior to entering the field? It could save time and money to know in advance what areas on which to focus fieldwork. The answer is simple, we can. In addition, later ground truthing of the area can only be further enhanced by advanced capability to know where to focus efforts and resources. This ability is readily available in the form of geographical information systems (GIS) spatial mapping, creating raster operations to focus on areas sharing attributes of known fossil locations. To serve as an example, known naturally occurring hominin fossil sites in Morocco and Algeria were used to create spatial maps highlighting potential hominin fossil sites containing the same attributes as known sites.

[153]  Proyecto La Flor

The excavations at Proyecto La Flor focused on investigating the prehistoric site of Conchal. Conchal is located approximately 1-2 km east of the Pacific Ocean, with its southern boundary connecting it to the Pacific via the Rio La Flor. This connection allowed access to the Pacific Ocean, while also allowing access to terrestrial resources. The natural and built landscape was an important resource for the inhabitants of Conchal and was what attracted these people to the area. Conchal was first potentially occupied during the Bagaces period. It was permanently settled during the Sapoa period, which continued into the subsequent Ometepe period. Through the utilization of the natural resources, molluscs in particular, the inhabitants created a built landscape of shell mounds. These mounds were composed not only of refuse, but also their ancestors. This area became a place to not only throw refuse and bury ancestors, but to lay claim. This claim was in the form of the created mounds, which was reinforced by the creation of more mounds. The buried ancestors in turn reinforced the living inhabitants claim over Conchal and its resources.

Lara-Pinto, Gloria (Universidad Pedagógica Nacional Francisco Morazán, Honduras)

Ethnic identification may go through different facets of redefinition that range from a mythical past to contemporary life. Such is the case of the Honduran Chortís, whose two geographically separate population nuclei present distinct social and economic characteristics in a region where the influx of diverse people and languages were recurrent prior to Spanish conquest. The indigenous enclave in Copán answers historically to the “Chortí” denomination, whereas the counterpart population in Ocotepeque has been known simply as “San Andrés Indians”. However, in 1994 both indigenous communities sought to vindicate their common ethnic ancestry before the state, a conception generally ignored in Honduras due to the loss of their language. Furthermore, this common ancestry was tempered by the late Nahua Pipil juxtaposition in the borderland shared with El Salvador, while simultaneously maintained in the frontier territory shared with Guatemala due to the actual and effective use of the Chortí language. The aim here is to contribute to the comprehension of these processes from the remote past to the present which led to the redefinition of an ethnic group “from within,” with the purpose to assert and strengthen their identity “outwards” in the specific context of an idealized mestizo nation.

Larkin, Karin (University of Colorado at Colorado Springs) and Jane Kelley (University of Calgary)

[202]  Recent Interpretations of the Ceramics from the Southern Zone of the Casas Grandes

While Dr. Linda Cordell was particularly known for her work in the Rio Grande, her passion for research and scholarship inspired projects throughout the Southwest/ Northwest and even beyond. Cordell’s mentorship and clear insight helped shape many research projects, including my dissertation research on the ceramic assemblages from the southern communities of the Casas Grandes Culture Area in Chihuahua, Mexico. Pottery has long been the yardstick of identifying the cultural affiliation of people who created these assemblages in the Southwest/Northwest as well as the basis for many other kinds of inferences. When the Proyecto Arqueologico de Chihuahua (PAC) began working in the Southern Zone of
the Casas Grandes Culture area, the project directors had only a handful of earlier research from which to draw upon. This left many unanswered questions and many avenues for research. Cordell’s insight recognized this potential. This paper presents recent research related to the production and distribution of the Viejo and Medio period ceramics in the southern regions of the Casas Grandes Culture Area. Using a diachronic approach we examine issues related to chronological sensitivity, regional and extra-regional interaction, and cultural affiliation.

Can You See Your Story Up Here? Letting Multiple Narratives Stand
Archaeologists regularly create narratives about our sites – through informal talks, presented papers, and reports. We must interpret the data – it is part of our responsibility. Yet, ours are not the only stories. Part of the joy of archaeology is that the landscapes and objects we investigate can often complicate existing interpretations. How do we, as professionals, allow room for multiple narratives? The Courthouse Site in Annapolis, Maryland – a post emancipation African-American neighborhood -- provides a case with which to explore value of multiple narratives.

Learning, Migration, and Identity in the Albuquerque Area during the Late Developmental to Coalition Transition
Over the last decade, archaeologists have increasingly searched for evidence for learners, as well as data on learning frameworks and the social context of learning. My research examines pottery from the Albuquerque District of the central Rio Grande during the late Developmental to Coalition period transition (ca. A.D. 1100-1300). I utilize both technological and decorative data in order to identify learners and characterize the structure of learning. This analysis expands on research about learning to consider the implications for broader social phenomena, including migration and identity.

Reconnaissance Survey in Djibouti: Evidence of Coastal Occupations in the Horn of Africa
The presence of the U.S. Navy in the Horn of Africa has led to the opening of a small but significant window into the prehistory of a poorly understood region. Surface reconnaissance conducted at the Camp Lemonier Navy base in the Republic of Djibouti over the last several years has allowed the Navy to inform base planning with a consideration of the local environment and cultural heritage. Surveys have documented several archaeological sites within the Afar Depression. Lithic and ceramic assemblages provide evidence of numerous occupations, including Late Stone Age cultures, and coastal adaptations along the Red Sea. A geoarchaeological study demonstrates heavily eroded soils with deflated soil columns, with minimal potential for intact, buried deposits. This paper will provide an overview of the local environment, a description of the artifacts recovered and a brief summary of the geomorphology and taphonomy of site areas, contributing to a small and slowly growing body of data for this critical area of African prehistory.

Permutations in Paleoindian Lifeways: 5,000 Years at Hell Gap
Models of hunter-gatherer response to spatial and temporal variation in resources and climate form the basis for ecological studies of hunter-gatherer archaeology. Such studies provide one means of understanding mobility, raw material use, subsistence, settlement, and technological organization. An unusual approach to land use studies relies on high-resolution excavation and analysis of chipped stone and fauna combined with tightly controlled chronostratigraphic and site formation studies at a single location within a complex, well-excavated stratified site. Our paper considers the range of variability in 5,000 years of Paleoindian occupation at the Hell Gap site, Wyoming. Paleoindians left at least 23
campsites at four localities with nine cultural complexes. These camps range from high density bone beds to ephemeral short-term occupations. Our research illustrates the depth of changing environmental, seasonal, and cultural existence seen at a single location. Various specialized analyses allow analytical expansion beyond the site to regional perspectives on hunter-gatherer mobility, raw material use, subsistence, settlement, and technological organization. Some of the earliest evidence for Paleoindian structures, overwhelming use of local chipped stone raw materials, and the absence of associated communal bison kills fit well with changing perspectives on Paleoindian existence throughout North America.

Lash, Ryan (Northwestern University) [106] Mapping Ritual and Economic Communities in Early Medieval Connemara, Ireland. This poster traces the interconnections between 7th through 13th century settlements in the seascape of northwestern Connemara, counties Galway and Mayo, Ireland. Mountainous and boggy, much of Connemara, Ireland provides a rugged environment for settlement. Early medieval documentary coverage for the area is poor, and what little is known about Connemara in the period comes from archaeology and folklore surrounding insular monastic sites. Evidence for contemporary secular settlements in the area is comparatively scant. In all, coastal Connemara’s landscape and settlement pattern fits poorly with dominant models of early Irish political economy as constructed from contemporary legal texts and archaeology in other parts of the country. Combining folklore evidence with survey and excavation data collected over the last 6 years, this study constructs a political economic model for early medieval Connemara that prioritizes sea travel and pilgrimage as bases for social entanglements. Mapping the diversity of early medieval settlement alongside saint cults and later territorial boundaries suggests the scales of economic interdependence and ritual interaction at play during the period. These findings are situated within anthropological considerations of the role of ritual in social integration and reproduction.

Lassen, Robert (University of Tennessee) and Jennifer Anderson (Texas State University) [318] The Post-Clovis Paleoindian Archaeological Sequence at Gault Gault has a multicomponent sequence of post-Clovis Paleoindian occupations spanning the Pleistocene-Holocene transition. Projectile point types from these components include Folsom, Midland, Plainview, Dalton, Golondrina, St. Mary’s Hall, Wilson, and Angostura. Interpretations of these components vary, with occupations such as Folsom and Midland likely representing short-term retooling stopovers, while others such as Angostura are more indicative of a wider range of residential activities. This research presents the contexts of these components at Gault, focusing on their spatial distributions across the site and on their chronological/stratigraphic relationships with each other. Because it is the most extensive Late Paleoindian component at the site, the Angostura horizon is also given particular attention via usewear analysis on projectile points and bifacial tools.

Lau, George (Sainsbury Research Unit, Univ of East Anglia) [162] Deer in Recuay Culture: Perspectives on Predation and Emerging Warrior Elites in Ancient Peru This presentation examines the role of deer in the archaeology and imagery of the Recuay culture (ca. AD 1-700), north-central Peru. It focuses on innovations in human interactions with deer among highland groups following the collapse of the Chavin ‘feline cult.’ Two main patterns are described: first, the acquisition/consumption of deer resources (white-tailed and huemul varieties); and second, new and unprecedented dispositions in deer representation (namely heads, antler adornments, and trophies). The presentation concludes that human predation on deer, given its relation to the hunt and ideology of
enemies, was crucial in the rise of local warrior societies and noble status.

Laumbach, Toni and Karl Laumbach (Human Systems Research, Inc.) [202] *Linda Cordell and the Cañada Alamosa Project*
The Cañada Alamosa Project, located in southern Socorro County, New Mexico, is in its fifteenth year, with field research completed and special analyses in progress. The systematic testing of four sequential sites has yielded an array of ceramic types that span 800 years and are associated with both northern and southern ceramic traditions. Over the course of those years, Dr. Linda Cordell inspired and encouraged project principals as they examined ceramic production and exchange by the compositional analyses of both ceramics and clay sources through the use of neutron activation analysis, petrography, and lead isotope analysis. Dr. Cordell also possessed a passion for research into the origins of corn in the Southwest. The discovery of small, 4000-year-old corn cobs in a buried horizon at the Montoya Site make the Cañada Alamosa one of only a few locations where early corn has been found. Dr. Cordell was instrumental in having a sample of this ancient corn included in a DNA analysis of the earliest corn in the American Southwest. Her impact on the Cañada Alamosa Project was profound and will continue.

Lauzon, Ashley and Barbara Roth (University of Nevada - Las Vegas) [32] *From Architecture to Households: Pithouse Excavations at the Harris Site*
Our work at the Harris Site has resulted in the excavation of 20 pithouses and a number of associated extramural features. Architectural and artifact data from these houses and features have allowed us to document differences that we see as tied to the presence of different types of social groupings, form autonomous households to extended family corporate groups. In this paper, we discuss the architecture of the excavated pithouses and how differences in architecture can be linked to differences in household organization.

LaValley, Stephen [324] *Middle and Late Archaic Obsidian Procurement and Land-Use Strategies in the Black Rock Desert and High Rock Country of Northwest Nevada*
The period of transition from the Middle to Late Archaic was a time of transformation for several aspects of prehistoric lifeways in the Great Basin. This paper addresses two aspects of this transition, obsidian toolstone procurement and land-use strategies, for the Black Rock Desert and High Rock Country of northwest Nevada. Recent results from X-ray fluorescence analyses of artifacts from Paiute Creek Shelter, Hanging Rock Shelter, Silent Snake Springs, and Smokey Creek Cave are compared to previous source provenance data and theories of obsidian procurement from the region. With data from more than 600 sites in the area, spatial analysis and site assemblage characterizations are employed to examine land-use strategies across time. Results indicate that no significant changes occurred in how obsidian toolstone was procured between the Middle and Late Archaic, contrary to previously established ideas. Results also illustrate a greater degree of residential mobility during the Late Archaic, as opposed to the logistical focus of Middle Archaic mobility.

Law De Lauriston, MacLaren (University of the Witwatersrand, Johannesburg, RSA) [217] *The Effect of Contact with Farmers on Hunter-Gatherers’ Lithic Assemblages: Use-Wear Analysis of Stone Tools from Holkrans, North West Province, South Africa*
Holkrans Rockshelter is perched in the outer rim of the Vredefort Dome, on a quartzite shelf, overlooking the Vaal River, in the Potchefstroom District, North West Province, South Africa. Thus far, excavations have identified two main phases of Later Stone Age occupation – pre-ceramic and ceramic – comprising three superimposed layers, dating approximately 2,000 ya, the late first millennium A.D., and within the last 500 years. The research aim is a better understanding of the effect of contact and interaction with herder-farmers on the activities of hunter-gatherers. This fits into a larger discussion that has come to be known as the Kalahari Debate wherein the two opposing viewpoints contrasted the immediate encapsulation and assimilation of the foragers into herder/farming cultures, against the continuation of the ‘pristine’ hunting-gathering way of life well beyond the time of contact. Reality was no doubt more complex and regionally variable, and a more nuanced view of the specific impacts on the Vredefort Dome hunter-gatherers has emerged through use-wear analysis of the Holkrans lithic assemblage. This may change the way we approach and interpret future LSA lithic analysis in southern Africa.

The St. Nicholas Cemetery Restoration Project
In 1943, the United States Navy acquired, through eminent domain, 6400 acres of prime farmland at Cedar Point, Maryland. Cedar Point was home to the town of Pearson, a Methodist church and cemetery, and St. Nicholas church and cemetery. The current St. Nicholas church was built in 1915 replacing the original 1795 church. One of the first projects in developing the base was to map all visible graves at the cemetery with names and dates when readily available and then bury the headstones atop each grave. In 2003, the authors petitioned the navy to resurrect and restore the head and footstones to its 1943 appearance. While initially the project was rejected, later commands agreed to the effort provided the Maryland Historical Trust would approve and issue an Archaeological Resources Protection Act (ARPA) permit. The fragile marble stones were broken due to pressure cracks and mishandling and very few remained intact. After 7 years of volunteer labor, 263 headstones were recovered and re-erected and once again, the cemetery appeared as it did in 1943.

Lawrence, Ken (SWCA-Texas State University), Brittney Gregory (Consulting Geoarchaeologist) and Charles Frederick (Consulting Geoarchaeologist-Geologist)

Geoarchaeological Investigations at Kelley Cave (41VV164) and Skiles Shelter (41VV165), Val Verde County, Texas.
In conjunction with the 2013 Texas State University Archaeological Field School excavations at Kelley Cave (41VV164) and Skiles Shelter (41VV165), a series of geoarchaeological samples were collected and analyzed. These samples (e.g., magnetic susceptibility and phosphorus) were collected from select excavation profiles within each of these arid rock shelter sites. This presentation discusses the preliminary results of these investigations, their interpretations, and how they correlate to the cultural deposits from the excavations.

Lazrus, Paula Kay (St. John's University)

Landscape Economics in Uncertain Times
During the period of Napoleonic Rule (1799-1816) the hill town of Bova (Calabria, Italy) was a relatively important center. Despite its social importance and abundant resources the community appears not to have been fully integrated into the larger economic system of the region. Hilly terrain, lack of good roads connecting the town and the coast and the density of vegetation in some areas would have dictated what crops were grown in particular localities. The connection between the accessibility of fields to both town and the wider regional market is utilized as one marker in an investigation of landownership and social situation opening a window into questions of income inequality that might otherwise not be apparent given the fact that individuals tend to have multiple holdings, across the landscape. This poster explores the spatial distribution of land and crops as a window into local economic dynamics

Lazzaris, Gerson Levi and Erika Marion Robrahn-González (UNICAMP)

Management of Urban and Archaeological Settings: A Case Study of the Port of Rio de Janeiro, Brazil
Archaeological research carried out recently in the port region of Rio de Janeiro has revealed a complex correlation between old and new historical structures related to the expansion of the city towards the coastline. Early evidence of an active commercial life connecting Rio to other overseas contexts consists of an old row of water-front warehouse, old streets, storehouses and other historical buildings. Dating to the eighteenth century, when Rio was the center of the Portuguese Monarchy, the material record comprises an important part of the colonial and post-colonial history of Brazil. This paper aims to explain the research strategies adopted to understand the urban complex. Beyond the scientific knowledge generated by our research, our additional goal is to translate this knowledge for local communities through the use of media technology and historical landscape reconstruction of the urban coastal zone. Furthermore, this cultural heritage is integrated into the new urban design planning correlating cultural
circuits, tourism and providing tools for the archaeological management of this historical heritage.

PIXE and Obsidian Sourcing in the Mediterranean Area

Particle Induced X-Ray Emission [PIXE] counts among the non-destructive ways of determining obsidians elemental compositions. We analyzed at two French facilities, AGLAE (Centre de Recherche et de Restauration des Musées de France, Paris) and AIFIRA (Centre d'Etude Nucléaire de Bordeaux-Gradignan), about 1,000 Upper Palaeolithic to Chalcolithic artifacts sampled in nearly 40 sites, from western Mediterranean to eastern Anatolia, and 100 others from related potential sources. Fifteen major and trace elements contents were obtained either from extracted beam (in room atmosphere) or in a vacuum chamber. The PIXE source data are in good agreement with that obtained in our laboratory by other techniques (ICP/AES-MS, EDXRF, EMPA, SEM-EDS). They allowed us to determine unequivocally the provenance of all the artifacts characterized by PIXE. Apart from non-destructivity, the technique is also attractive as it can be applied to small (>1mm2) samples.

GPR Prospection for Unmarked Graves in Glaciomarine Silts and Clays: A Case Study from Maine, USA

The success (and failure) of many ground-penetrating radar surveys in cemeteries is often a direct result of local field conditions. Decades of GPR research have shown that certain sediment types, like dry, stratified sands, provide favorable conditions. Others, like wet, conductive silts and clays, are generally considered poor candidates for GPR. This paper presents the results of a two-season GPR survey in Bangor, Maine where prospection for unmarked graves was undertaken in Presumpscot Formation, a Pleistocene-aged glaciomarine silt and clay. This project was undertaken as a part of a larger effort to characterize human burials with GPR and to correlate geophysical signatures, sediment type, and age of interment. While the Presumpscot Formation was chosen as an example of sediment with unfavorable characteristics, it actually provided the most highly resolvable graves of all the glacial sediments tested. The success of the survey was likely due to the Presumpscot Formation's sedimentology; it is a sediment comprised of clay-sized particles, rather than a mineralogical clay derived from weathering in place. This case study suggests that the resolvability of graves in glaciomarine silts and clays is quite high, and that there are variations in data collected during summer and winter surveys these settings.

Community Organization and Culture Change in the Chuska Valley, New Mexico
Over the many centuries spanning the Archaic and Anasazi occupation of the Chuska Valley, many communities formed, endured, or faded in the face of shifting patterns of regional migration, the emergence of new cultural systems, and other dimensions of social and environmental change. In this paper, we examine the internal organization of some of these communities, comparing and contrasting community scale, patterns of clustering or dispersal, the presence and role of integrative architecture, and other community attributes over space and time. In particular, we consider the relationship between these dimensions of community organization and the role of persistent places and communities within the broader Chuska Valley landscape. These analyses provide a basis for tracing the ways in which the organization of community space and architecture contributed to the endurance of prehistoric occupation in some locales and the more fluid, shifting nature of occupation in others.

Turkeys of a Feather Flock (and die) Together: Exploring the Management of a Resource in the Southeastern US through Individual Life Histories

It is widely accepted that turkeys (Meleagris gallopavo) were important in the diets of Missippian Period peoples of the Southeast, yet we do not fully understand how turkey populations were managed. Ethnohistoric documents and ethnographic accounts suggest that the Cherokee and other southeastern groups baited turkeys to hunt them more easily and raised turkey poults for reliable and easy access to meat and feathers. We argue that if turkeys were being kept and raised there should be evidence to support this. Contextual information is important as it seems clear that some turkeys were raised while others were hunted in the wild. Osteological evidence based on morphometric data of archaeological specimens can be compared to the same data from modern wild and domesticated specimens to determine size differences. In this paper, we present data on a sample of turkeys from a dated context excavated at the Fewkes Site in Middle Tennessee. Given the context it appears that these specimens lived and died together ca. A.D. 1250. We explore the life histories of these turkeys as individuals and as a group, and use the data to discuss the multiple roles of turkeys as a managed resource in the late prehistoric southeast.

Rocky Mountain Ice Patches as a Rich Source of Archaeological and Paleoenvironmental Data

Organic artifacts recovered at melting ice patches provide context for the inorganic elements that comprise most of the archaeological record. A recently recovered coiled basket, an almost-certain product of women’s craftsmanship, speaks to group composition, while ownership marks on hunting implements speak to group or individual identity. In addition to a review of the tool classes represented at ice patches, this paper summarizes the associated biota as revealed by frozen organic lags recovered through coring. Finally, the analysis of wood from preserved tree stands illustrates the dynamic nature of these environments during warm periods.

'Asht'ño Yóhoool’aah (Learning to Weave): The Cultural Transmission of Technological Style in Navajo Textiles

For Native American Nations, cultural continuity is a means of connection to our past and a stabilizing element for our societies in the present and future. Cultural continuity exists because of our means of knowledge transmission through generations. There is little understanding in archeology on how the process of learning impacts, particularly in traditional knowledge, technological styles and their evolutionary processes. My research examines how learning networks and technological styles are reflected in Navajo textiles and production through the study of designs and weaving techniques. To support my research I analyzed rugs woven by intergenerational weavers and used archival interviews. Although external economic influences have been present through time which shift various demands for certain styles/patterns, technological styles remained mostly unchanged. In addition, the research indicates that technological styles are transmitted through the generations. This study is important to
archaeology because understanding learning networks allows us to understand how the learning process affects the patterning of material culture in time and space.

[60] Vocación defensiva – vocación simbólica: nueva mirada sobre los asentamientos encaramados en el valle de Acámbaro durante el Postclásico tardío
Los trabajos arqueológicos llevados a cabo desde los años 1970 en el valle de Acámbaro sobre el patrón de asentamiento en el transcurso del Posclásico tardío revelaron una ocupación privilegiada de los relieves, cumbre de mesetas y pendientes altas. Desde entonces, los investigadores identificaron la ubicación dominante de los sitios como un elemento defensivo característico. El contexto político conflictivo en esta zona fronteriza del reino tarasco frente al imperio mexica, ampliamente evocado por las fuentes escritas del siglo XVI, hace hincapié en esta interpretación. Sin embargo, estos estudios se basan en datos arqueológicos poco abundantes y hacen caso omiso la multiplicidad de las formas y de las funciones de estos asentamientos encaramados, así como el lugar preponderante de estos cerros en el paisaje ritual prehispánico. A partir de una confrontación sistemática de datos arqueológicos recientes y de la documentación escrita, esta comunicación propone confrontar diferentes aspectos tipológicos y simbólicos, con el objetivo de comprender mejor las lógicas de asentamiento en vísperas de la Conquista.

[113] Mammals on the Move: The Zooarchaeology of Pre-Columbian Circum-Caribbean Interactions and Economy
In addition to traditional studies of pottery and settlement patterns, archaeologists working in the Caribbean are focusing on other classes of artifacts and new methods of analysis to better understand the nature and nuances of precolumbian interactions among the islands and circum-Caribbean region, including mainland South America. In this presentation, we discuss the role and potential of zooarchaeological data in studies of human migration, interaction, trade, and economy during Caribbean precolumbian history. We present new research and recent zooarchaeological and isotopic data demonstrating how the manipulation of small mammals may have been both socially and economically significant; including the translocation and introduction of both wild and domestic South American mammals (e.g., agouti, opossum, and guinea pig), as well as possible management of native hutia. Our
results focus on the second half of the Ceramic Age (post A.D. 500), include Greater and Lesser Antillean sites, and provide a foundation from which to formulate additional studies.

LeFebvre, Michelle [139] see Kimura, Birgitta

Leftwich, Brent
As one of the most ubiquitous features throughout the Sierra Nevada of California, bedrock mortars are synonymous with hunter-gatherer subsistence during the Late Prehistoric, particularly in reference to the acorn economy. Although much less common, large, tub shaped features, often referred to as “Sierra basins,” have garnered more recent, and somewhat controversial, attention as potential salt producing facilities near natural saline springs. The location and morphology of these permanent, immovable features can be used to create models of prehistoric behavior in the region. A research project along the North Fork of the Mokelumne River examined functional variables in mortar depth from over 300 bedrock mortar sites. Using quantitative methods and GIS spatial analysis, this project elucidated settlement and subsistence patterns by juxtaposing site size and complexity, elevation, and dominant vegetation. This approach revealed a pattern of permanent settlement, central place optimization, and risk buffering on the regional scale, while resource procurement and processing at the individual site level proved highly variable. In this most recent work on the project, Sierra basins (whether natural or cultural in origin) have been added to this analysis to examine strategies for salt harvesting in the context of wider resource exploitation.

[91] Teotihuacan Figural Representations: Ancestor or Deity?
Teotihuacan, Mexico’s major cosmopolitan city until its demise in the mid-6th century, was a place of origins, laws, and power. It became a source of inspiration as a tollan, with its highly recognizable artistic styles echoing across ancient Mesoamerica. Google-eyed masks and warrior-style headdresses embellish the individuals of many Early Classic Maya monuments, but Teotihuacano art is largely deemed impersonal. The human figures represented are not believed to represent actual individuals rather deities, unlike their Maya counterparts who utilize ancestors and rulers in Teotihuacan garb. This paper considers recent studies on the identity of human figures in Teotihuacan imagery, which tend to vacillate on whether or not actual individuals are represented.

[337] Moving beyond Traditional Full Coverage Survey: LiDAR at Angamuco, Michoacán, Mexico
Since the early 2000s LiDAR has been used in various field settings in support of archaeology. In 2010, after two fieldwork seasons devoted to the mapping of structures of a previously unknown settlement on a malpais in the Lake Patzcuaro Basin of Mexico, 9 km² of LiDAR data were obtained for the site. During the next two field seasons LiDAR derived products were integrated into the fieldwork and mapping efforts. This paper describes the process that led to the use of LiDAR within the Legacies of Resilience project in the Lake Patzcuaro Basin, Michoacán, Mexico. It details the creation of the LiDAR derived products used in the mapping effort, the results of the LiDAR supported ground survey and mapping and a comparison to the previous full-coverage surveys which used sub-meter GPS surveying methodologies to map structures within the newly identified pre-contact urban area. Based on our experience recommendations are made for best practices in integrating LiDAR derived products into archaeology surveys which focus on dense urban areas under semi-dense tree cover.

[202] Mesa Verde Migrations
Migrations and the abandonment of sites and regions were long-term interests of Linda Cordell. Her dissertation on Mesa Verde and her later work at Rowe Ruin directly addressed these issues. We revisit this surprisingly contentious topic, evaluating models developed from University of Colorado research at Pinnacle Ruin in southern New Mexico in light of larger studies of regional abandonment and population movement. Cordell’s approaches and ideas are integrated into our analysis.

[218] Temporal Changes in Marine Shellfish Use: A View from the North Atlantic

The proposed paper will report on test excavations conducted in a shell midden (BjCo-02) located on the south side of Maligomish (Indian Island), a small island located off the northeastern coast of Nova Scotia. Archaeological, archival, and historical evidence indicates that the indigenous Mi'kmaq have used Maligomish for at least the past two thousand years. In collaboration with the Pictou Landing First Nation, whose reserve lands include Maligomish, a complete survey of the island and limited test excavations were conducted to determine if the island was used year-round or only seasonally during the pre-contact period. Although the recovered data were insufficient to answer that question, the recovered remains of shellfish show a marked shift in species representation over time, with Crassostrea sp. (oyster) predominating until ca. A.D. 1200 when Mya arenaria (soft-shell clam) becomes the overwhelmingly dominant species. This paper will consider whether the quantity and preservation of the collected shells is sufficient for analyses that would allow us to infer broader changes in the environment and resource intensification. Such changes have increasingly engaged researchers engaged in archaeomalacology in the southeastern United States, California, and South America. This paper will provide a unique perspective from the north Atlantic.

[318] Converging Lines of Evidence: Clovis Diet at the Gault Site

Archaeologists have long questioned Clovis foragers as solely big game hunters and a more sophisticated picture of Clovis hunter-gatherers, representing a mosaic of complex adaptations has emerged in recent years. Investigations of the diet at single sites such as Gault contribute to a picture of regional variability in Clovis subsistence. While well known for including a wide range of species, the Gault faunal assemblage is poorly preserved and highly fragmented and just 5% is identifiable to genus or species. In order to compensate for poor faunal preservation, new spatial analyses have been combined with lithic and faunal data to isolate Clovis subsistence resources from the paleontological background noise at Gault. These lines of evidence converge and reveal that, similar to most ethnographic or archaeologically known foragers, Clovis peoples made seasonally variable subsistence choices which included a range of both plant and animal species.

[34] “Garden Cities” in the Classic Maya Lowlands? Settlement and Land Use Patterns at La Joyanca (Guatemala) and Río Bec (Mexico)

Despite a general consensus in Lowland Maya settlement pattern archaeology regarding the existence of "agrarian cities" during the Classic period, there is little current research aimed at defining precise models of these agrarian systems. Infield agriculture poses a methodological challenge: how can we identify archaeological evidence of plots producing staple crops, whether domestic or kitchen gardens, orchards, or infield? And how can we link these forms of evidence to material remnants of houses and households? This paper will begin with a brief synthesis of recent advances in the study of Maya settlement patterns and agriculture. It will then present the results of two recent investigations carried out at the sites of La Joyanca, Guatemala, and Río Bec, Mexico. Through a multidisciplinary and multi-scalar research strategy developed collaboratively with geographers, it has been possible to formulate two distinct models of territorial occupation and land use, in relation to social groups.
Lennen, Joel
[327]  **Terminal Woodland-Early Mississippian Interface at the Jackson Lake Site**
The Terminal Woodland-Early Mississippian Interface (A.D. 1075-1200) in central Alabama saw the coexistence of local Woodland communities and Mississippian peoples who were moving throughout the Southeastern United States. These interactions were experienced at several sites located around modern-day Montgomery, including the Jackson Lake Site that lies west of the Alabama River. Interactions between local Woodland and Mississippian communities may have taken place amongst generations of individuals who dwelled at the Jackson Lake Site. This paper analyzes previous investigations at the site, and in conjunction with future research, will help us address questions regarding the Terminal Woodland- Early Mississippian in central Alabama.

[157]  **Two Cases for Archaeological Geophysics: Comparing the Application of GPR and Magnetometry at Late Bronze Age Sites in Armenia and Cyprus**
In a 2010 article in Antiquity, Conyers asserted, “geophysical methods in archaeological research have progressed to the point that they can be used as much more than exploratory tools” (2010:183), in response to the assumption that geophysical methods are strictly for prospection in archaeological research to indicate areas of interest for future excavation. Geophysics is, arguably, providing more archaeological data than ever before; however, in order for these data to have a sustained impact on the field, projects must understand the promise and limitations of geophysical survey, and effectively implement survey as an aspect of larger research design. Here we report on Project ArAGATS in Armenia and the KAMBE project on Cyprus, both of which have recently employed geophysical survey (specifically magnetics and ground-penetrating radar). Our goal is to compare not only the techniques deployed and data collected, but, perhaps more importantly, how these geophysical surveys impacted the research agendas for each project in an effort to illustrate how geophysical survey can be effectively implemented in archaeological research frameworks.

Leon, Alysia (Flagler College) and Courtney Van Gemert (Texas A&M University)
[285]  **Social Structure Inferences from Funerary Remains Located at the Site of Panquilma in Cieneguilla, Peru**
Funerary interments allow insight into the social hierarchical composition of prior societies. Through funerary analysis at the site of Panquilma, which is located within the Lurin Valley of Cieneguilla, Peru, generalizations can be made in regards to the structure of social classes during the Late Intermediate Period. Burials discovered in the public sector as well as the domestic sector exhibit different characteristics in regards to the treatment of the deceased, tomb appearance and funerary offerings in comparison to those found within the funerary sector. Prior to the examination of the funerary sector at the site it was believed that the people of higher importance were buried within the household compounds of the site and the lower class citizens were intermitted in the funerary sector. Further examination of the looted remains discovered in the funerary sector and public sector in comparison to the untouched human remains located within the domestic sector lead us to believe that the prior statement no longer holds validity. Through the analysis of the skeletal remains in terms of pathologies, sex, age and trauma along with grave goods, different conclusions can be made in regards to the social structure of the Ychsma population.

[140]  **The Discovery of an Omechicahuaxtli from Postclassic West Mexico: Analysis and cross-cultural examination of human bone musical trophies**
The modification of human bone into musical trophy items is a practice common across the ancient...
world. They have been recovered in the Americas from California to the Andes. The form of processing and functional significance varies. The most commonly known are symbolic, associated with ritual sacrifice or warfare, although human bone instruments are also recorded in fertility and funerary rituals. The omechicahuaxtli is specific to Mexico and refers to a musical rasp. This contribution reports on an omechicahuaxtli recovered from a Postclassic shaft and chamber tomb in Jalisco. Artistic representations of rasps are known from this region. To date, this appears to be the only West Mexican omechicahuaxtli recovered from an archaeological excavation and systematically analyzed. The rasp is broken, possibly assisted by a sacrificial ‘death’ prior to interment. At least 23 notches are visible with varying distance, depth and polish. Microscopic analysis of the notches was undertaken to examine how the musical rasp was manufactured and used. This analysis identified tool striations and extensive wear patina, demonstrating the rasp was not just a symbolic object, but had extensive use prior to inclusion in the funerary context, thus providing insight into prehistoric ritual world of West Mexico.

Leriche, Christina [189] see Rhodes, Jill

Lerman, Melanie (California State Polytechnic University, Pomona) and Austin Ringelstein (California State University, Northridge) [142] Glass Beads from Catalina Island: A History of Trade and Contact Catalina Island, off the coast of southern California, has a rich cultural history that has offered archaeologists the ability to explore trade relations and culture contact between the Gabrieleno/Tongva people and European explorers during the protohistoric period. However, the dynamic of the relationship between Europeans and native peoples is still unclear. The village of Nájququar, located on the Isthmus of the island at present day Two Harbors, is a large site (SCal-39) that offers an excellent opportunity to examine these questions. Research using X-Ray Florescence and other methods is applied to the analysis of glass beads, a commonly exchanged commodity throughout California, that have been found in previous excavations in Nájququar. With the resulting spatial and temporal data, the degree of influence from contact and trade with Europeans can be determined with more precision.

Lerner, Shereen (Mesa College) [96] Challenging the Status Quo
In 1988 educating the public on archaeology was considered outside the mainstream of archaeological research. It was a luxury, an option, and not widely accepted by the archaeological community. A group of archaeologists came together to challenge the old way of thinking and developed plans to integrate educating the public into mainstream archaeology. Over the last 25 years, we have watched the role of public archaeology grow into its own profession and become a regular component of archaeological research proposals. What are the benefits in having moved in this direction? What does our future hold with regard to improved communication with the public?

Leslie, David (University of Connecticut), Sally McBrearty (University of Connecticut) and Gideon Hartman (University of Connecticut) [209] Stable Isotopic Evidence for Landscape Environmental Reconstructions, Kapthurin Formation, Kenya
The Kapthurin Formation, a part of the Middle Pleistocene sedimentary sequence of the Kenyan Rift Valley in the Lake Baringo basin, documents the transition from Acheulean to Middle Stone Age (MSA) technology. The MSA is of particular importance, as it marks the appearance of modern behavior, and the emergence of our own species, Homo sapiens. Archaeological and paleontological sites from two time intervals, 509 ± 9 thousand years ago (ka) to 543 ± 4 ka, and 235 ± 2 ka to 509 ± 9 ka, were sampled for stable isotope values of fossil pedogenic carbonates, useful in reconstructing environments exploited by MSA and Acheulean hominins. Sample preparation of fossil carbonate nodules followed conventional methods. Δ13C and Δ18O values derived from this study and a previous study on tooth enamel indicate that landscapes in the Lake Baringo basin were composed of diverse micro habitats, ranging from wet forested (C3) environments to arid grassland (C4) environments between 545 ka and 235 ka. These results will be useful in determining if there is evidence for differential utilization of landscapes, environments, and resources at MSA sites when compared with Acheulean sites, as has been suggested by other researchers.

[173] Kitandach (GbTo-34) Revisited: Using Percussion Coring to Explore a Large Shell-Bearing Site in the Prince Rupert Harbour, British Columbia, Canada

Large shell-bearing sites are stratigraphically complex and the depositional behaviours that result in their formation over time are varied and often poorly understood. Very large and deep sites are challenging to excavate and the limited areal coverage of most excavations provide a limited sample of the entire site. This poster presents the results of a detailed surface and subsurface investigation of Kitandach (GbTo-34), a 10000 m² shell-bearing village site in the Prince Rupert Harbour, British Columbia, Canada that has been occupied from 5700 BP until European colonization. We build on intensive coring methods employed in the region in the last decade in which core samples are taken on a grid across the entire site, analyzed for major stratigraphic transitions across wide areas, and intensively radiocarbon dated to understand the timing of developments, expansions and accumulations across the location. The site was excavated by the Canadian Museum of Man (now the Canadian Museum of Civilizations) in the early 1970s; our analysis allows us to revisit this legacy of archaeological work and combine the results of traditional large scale excavation and wide ranging subsurface coring and radiocarbon dating for a refined view of an otherwise methodologically daunting site type.

Leventhal, Alan (College of Social Sciences, San Jose State University), Les Field (Department of Anthropology, University of New Mexi) and Rosemary Cambra (Chairwoman, Muwekma Ohlone Tribe)

In the twentieth century, the erasure of the Ohlone, the indigenous people of the San Francisco Bay Area, was constructed around the unilateral and arbitrary termination of their relationship with the federal government in 1927, and an “extinction sentence” inscribed by Kroeber in his authoritative Handbook of the Indians of California (1925). The processes by which the presence of Ohlone peoples in their aboriginal territories were decisively obscured and disestablished initiated during the Spanish colonial regime involved the transformation of geography and placenames that not only erased the Ohlones and their history, but also filled that absence with colonial presence. This study closely interrogates “nominative cartography” - - the power to erase and implant, to disappear but also to substantiate, and to displace and replace in the service of colonial projects - - by tracing the changing map of Ohlone homelands as they were transformed by and during the colonial regimes, using the specific case of the neophyte cemetery at Mission Santa Clara. This case underscores that the Ohlone did not disappear and their persistence is reflected in contemporary strategies to regain their federally recognized status that also involves efforts to re-establish their presence in the broader contemporary cultural landscape.

[330] Land: A Symbol of Existence

Within most societies of the 21st century, people perceive land as a commodity on which one farms or extracts the important resources associated with it, i.e. food, lumber, minerals, or oil. This perspective on land has played a critical role in the recent history of the Americas. But we ought to regard land through a more nuanced lens. For many people it operates as far more than just a commodity: it symbolizes and fashions the very existence of individuals and groups. The symbolic representation of identity through association with land has become a flashpoint in the modern struggle of Native Americans for recognition and rights. Not only do we see this within the United States or Canada, but also similar disputes and conflicts are evident throughout the Americas and across the globe. We focus these two competing views of land (commodity and complex symbol) within the Maya regions of Central America, specifically Belize and Mexico. We also consider that when land is scarce and identity is divorced from land, identity itself often becomes commodity - a phenomenon commonly encountered in tourist centers throughout the area.

Levi, Laura (The University of Texas at San Antonio)

[292] An Economy of Movement

Movement is considered central to placemaking behavior. Typically, places are framed as loci of the
familiar, of face-to-face interactions. In the literature, therefore, places have come to connote the small-scale or local. This paper will argue to the contrary that movement is a multi-scalar phenomenon the effects of which serve to integrate disparate sites of experience. Using the Programme for Belize archaeological data base, I will explore relationships among temple architecture, processional pathways, and markets. From this analysis, a case will be made for the primacy of movement in the forging of regional coalitions among the ancient Maya.

Levin, Maureece (University of Oregon)
[298]  Paleoethnobotanical Indicators of Plant Food Production: A Contextual Approach from Pohnpei, Eastern Micronesia

Food production systems can be evaluated through a number of means, including proxy indicators and direct evidence for cultivation. Paleoethnobotanical data can provide direct indication of prior plant presence and use, but they must be contextualized, as they differ in the questions they can address in any given environment. This paper evaluates the potential of direct paleoethnobotanical indicators for understanding questions of food production in the tropical Pacific, drawing on Pacific Islands reference materials and an archaeological case study from Pohnpei, Federated States of Micronesia. In this context, plant remains address questions related to human relationships with the environment, changes in human diet, and the development of complex social systems. However, differential preservation related to the tropical island environment, the production of durable remains, and the types of features and artifacts where plant remains are found limit the types of remains that are recovered. Thus, this paper examines both the potential of common Pacific economic taxa to produce recoverable plant remains and the ways in which these remains have actually been preserved by the Pohnpeian social and physical environment.

Levine, Marc (University of Oklahoma)
[83]  Cotton Kingdom: Textiles and Trade at Postclassic Tututepec

Tututepec was among the most powerful Mixtec capitals of Late Postclassic (AD 1100-1522) Period Oaxaca. This paper begins with a discussion of how sociopolitical organization at Tututepec differed from that of the more well-known Mixtec polities or yuhuitayu from highland Oaxaca. I argue that some of these differences can be explained by Tututepec’s political economy and its role as a regional trade center. Tututepec’s status as an entrepot was strengthened through the local production of cotton thread, which was in great demand throughout Mesoamerica at this time. The proliferation of spindle whorls found across Tututepec and from household excavations demonstrates the importance of cotton thread production to Tututepec’s economy. Apart from economic exchange, the cotton trade also facilitated an exchange of ideas and practices. Based on an interregional comparative stylistic analysis of Postclassic spindle whorls, I explore how disparate communities of spinners shared technological knowledge that facilitated the production of high quality cotton thread.

[65]  Transdisciplinary Research and Historical Biblical Archaeology: Cyber-Archaeology and the Museum of the Future

The 2013 UC San Diego international conference concerning “Israel’s Exodus Between Text and Memory, History and Imagination” included an exhibition of transdisciplinary research (team science) that involved scientists who contributed their unique expertise to attempt to solve an ancient historical problem. This involved a specialist team of archaeologists, Biblical scholars, Egyptologists, geoscientists, computer scientists, engineers, and digital media technologists who used scientific visualization and media tools to show how a team approach could contextualize one of ancient history’s great mysteries – the Israelite Exodus from Egypt. The paper discusses the project that involved transforming a reconfigurable performance space into a 21st century museum space using new visualization and audio technologies to present original archaeological and geoscience research for both scholarly and public outreach.

First Steps to an Archaeology of Masculinity in the Southeastern U.S.

The late prehistoric (ca. A.D. 1000-1600, encompassing Mississippian and Late Woodland periods) southeastern U.S. provides us with several rich sets of data from archaeology, bioarchaeology, ethnohistory, ethnography, and linguistics. While several archaeologists have begun to explore ramifications of gender in this time and place, there has been little or no focus on masculinity itself. The archaeological record includes significant evidence that inter-personal violence of various kinds was part of the life experiences of communities in the region. So, there are several intriguing questions to be explored about the interconnections among personal identity, the ideology of masculinity, and the experience of violence. In this paper, I take exploratory steps to lay out the issues and potential evidence, and to consider how researchers’ biases may influence our analyses.

Lewandowski, David (Northern Arizona University)

Examining the Social Networks during the Pithouse-to-Pueblo Transition in the Mogollon Highlands

This paper examines the social networks that existed in the Mogollon Highlands during the pithouse-to-pueblo transition (A.D. 850-1100) using Social Network Analysis (SNA). The research focuses on the changing social networks that accompanied the appearance of pueblo architecture and prevalence of Cibola White Ware relative to Mimbres White Ware in the region around A.D. 1000. My research follows and tests the models set forth by previous SNA studies in the Southwest by using ceramic wares to build ties between sites creating the social networks. The relationship between social and geographical spaces within the region can be examined by combining SNA with GIS. I also examine changes in site centrality with emphasis given to the placement of Great Kiva sites within the network, exploring their potential as centers for exchange of commodities and ideology. Previous SNA studies in the American Southwest have demonstrated the potential for this type of analysis in examining cultural phenomena in prehistory such as migration and demographic changes. This paper uses SNA to examine a major cultural phenomenon not addressed in the previous SNA studies, the pithouse-to-pueblo transition.

Lewarch, Dennis (Suquamish Tribe)

Aztec Period Lithic Tool Production, Distribution, and Use in the Coatlan del Rio Valley, Morelos, Mexico

Debitage, formed tool classes, and use-wear traces on stone tools from eight Aztec period sites in the Coatlan del Rio Valley of western Morelos, Mexico, provide insights into the manufacture, distribution, and use of obsidian, cryptocrystalline, and ground stone artifacts. Data from 3,500 4-x-4-m surface collection units and maps of areas between collection units are used to identify obsidian and vesicular basalt workshops and to calibrate the flow and use of stone tools among more than 350 Aztec period houses in the valley. Valley-wide stone tool densities quantified by residential midden and extramural workshop area provide bench marks to identify households with greater access to imported obsidian and to identify house complexes exhibiting a wide range of functional classes. Quantitative differences among sites and households demonstrate complex patterns of provisioning, household consumption, and household craft production. Aztec period economic organization inferred from analyses of lithic artifact assemblages corroborates complex domestic multicrafting patterns noted elsewhere in Morelos.

Lewis, Helen (University College Dublin)

The Celtic Tiger and Underdeveloped Geoarchaeology in Ireland: Issues Arising From Skewed Applications in CRM

A certain level of geoarchaeology is a standard in CRM world-wide (e.g. geophysical survey). Where interventions are conducted, however, the application of geoarchaeological approaches varies enormously, despite the premise that interpreting context requires at least a fundamental appreciation of soils, sediments, and landform history. Depending on the educational backgrounds of archaeologists, local traditions in the discipline, and the expectations of industry regulators, some CRM units regularly apply geoarchaeological assessment in excavation and post-excavation, while others never do. These decisions constrain the value of site interpretation, dating programs, and the usefulness of results for future research investigations ('preservation by record'). In the Republic of Ireland, despite an early interest in geoarchaeology, and a recent construction boom employing thousands of CRM archaeologists, while certain traditionally-important environmental approaches are extremely well-developed, others, including geoarchaeology, never quite got off the ground, beyond geophysics and 'traditional' wetland studies. The

[160] Chasing Clusters: Analysis of Activity Areas to Determine Site Type at the Locarno Beach Phase (3500-2400 B.P.) Site 45WH55, Chuckanut Bay, Washington

In the Pacific Northwest the Locarno Beach Phase (3500-2400 B.P.) is viewed as a temporally intermediate, yet distinct phase between the Charles Culture (4500-3500 B.P.) and Marpole Phase (2400-1500 B.P.). Current understanding of settlement and subsistence practices during the Locarno Beach Phase suggests a drastic shift from forager to collector strategies and a site-type dichotomy of residential base camps and seasonal, limited-activity sites.

Site 45WH55 is a prehistoric shell midden site with radiocarbon dates (2750-2450 B.P.) from the latter half of the Locarno Beach Phase. Located on Chuckanut Bay in Northwestern Washington and the Southern Gulf of Georgia region, analysis of this site will contribute to the overall understanding of the time period. Through statistical analysis of the lithic and bone assemblages, I argue that 45WH55 closely resembles a residential base habitation site. However, rather than being the central base of a far-ranging, logistical organization with accessory limited-activity sites, this site appears to have exploited a largely local catchment area. Based on these conclusions, I propose that the current dichotomy should function more as a spectrum, in which some groups established bases in ecologically rich environments that would combine the functions of a residential base and its accessory stations.

[160] Chair

Lewis, Jason (Stony Brook / Rutgers), Sonia Harmand (Turkana Basin Institute, Stony Brook University, S), Hélène Roche (CNRS, UMR 7055, Préhistoire et Technologie, Univer), Michel Brenet (Inrap, Centre mixte de recherche archéologique, Do) and Guillaume Daver (Maître de conférences IPHEP-UMR 7262 (CNRS))

The manufacture and use of tools by hominids have been studied extensively by archaeologists, and also recently by primatologists on that of non-human primates, all of whom appreciate the relevance of tool-use and tool-making in understanding the origins of technology and the evolution of human behavior. Over the last few decades, there has been growing consensus on the probability of hominin tool manufacture before the Oldowan technocultural complex at 2.6 Ma. But did the earliest stone knapping develop naturally from pre-existing pounding behaviors, or did it appear de novo as direct hard-hammer flaking for cutting edges? The bipolar and passive hammer percussion techniques are biomechanically similar to the actions employed by non-human primates when engaging in pounding behaviors, but they have been little studied in replication experiments aimed at understanding the development of the earliest hominin lithic technologies. Recent archaeological discoveries made by the West Turkana Archaeological Project and initial results from a new experimental program are presented here showing that bipolar and passive hammer percussion are expedient techniques for producing sturdy cutting flakes and trenchant cores, and that Pliocene hominins may have been more capable with these gestures than with direct hard-hammer percussion.

[317] Strontium Isotope Variability in Range Creek Canyon, Utah: A Pilot Study

This study presents a first approximation of strontium isoscapes in Range Creek Canyon, Utah. Biologically available strontium was assayed by sampling Chrysothamnus naseosus from ten locations. Significant differences between 87Sr/86Sr from sites on the Colton, Flagstaff and North Horn formations allow the upper and lower sections of the canyon to be isotopically distinguished from one another. Sites in the lower canyon can also be distinguished from nearby alluvial deposits in Desolation Canyon. Strontium samples from stream and spring water indicate a fourth source of strontium above our sample area—perhaps associated with the Green River Formation which caps the Tavaputs plateau. Stream
water approximates soil $^{87}\text{Sr}/^{86}\text{Sr}$ but a 'lag' is noticeable on the intra-canyon scale. Implications for strontium analyses in Range Creek, Fremont and regional archaeology are discussed.

LI, YUQI (Washington University in St. Louis)

[92] Late Bronze Age (1900-1500 B.C.) Copper Metallurgy and Interactions between Sedentary and Mobile Groups in Southern Uzbekistan

Southern Uzbekistan was inhabited both by mobile groups and sedentary people in the Late Bronze Age (1900-1500 BC). How these groups interacted in copper metallurgy was the main research question of this paper. Two sites were chosen as representatives of each group. Muminabad is a cemetery site located on a foothill of the Upper Middle Zerafshan River, Samarqand region. Based on the Andronovo type burial goods recovered from this site, Muminabad most likely belonged to mobile groups. About 200 km southwest to Muminabad, in a oasis of Northern Bactria, stands the largest early urban site in Central Asia—Djarkutan. Chronologically, Djarkutan also largely belongs to the Late Bronze Age. From both sites, 25 bronze artifacts in total were analyzed. Composition analyses of these bronze were conducted with a Portable X-ray fluorescence (XRF) spectrometer. Comparison of their bronze compositions shows that these two sites probably had used copper ore from the same sources. This result shed light on the metallurgical interaction in particular and day-to-day interactions in general between the mobile and sedentary groups in Southern Uzbekistan in the Late Bronze Age.

Lieb, Brad (Chickasaw Nation)

This study is based on the premise that past ceramic practices which yield recoverable results reflected and structured multivalent identities of their producers and users. Natchez people of two different towns resettled separately among the Chickasaws in Mississippi during their temporary refuge there in the 1730s, following their expulsion by the colonial French from traditional Natchez homelands in the Natchez Bluffs region of the Lower Mississippi Valley. By examining variability in ceramic practices in the three independent domains of clay body composition, vessel form, and surface decoration, this study seeks to parse out the material evidence of past practices which can inform on subtle, yet meaningful, dispositions related to Natchez village and ethnic identity as well as assimilation in their diasporic resettlements. By extension, this study is relevant to other, even pre-Contact, long-distance migrations of tribal social segments, given the historical documentation and pronounced differences between traditional Natchez and Chickasaw pottery practices prior to their short-term co-residence in the Chickasaw Oldfields near present-day Tupelo, Mississippi.

Lieber, Mallary (University of Missouri-Columbia), Christine Van Pool (University of Missouri-Columbia) and Gordon Rakita (University of North Florida)

[44] Pottery in the Northern Ramos Zone: The Ceramic Assemblage from 76 Draw

The Animas Phase area includes settlements associated with many different archaeological cultures, each of which is reflected in specific pottery types. These types are generally found on the same sites, but it is unclear whether this reflects some sort of general synthesis among the cultures (e.g., people affiliated with the Salado, Medio period, and El Paso phase lived at the site together) or if it reflects trade among sites that produced different types of pottery. One means of addressing this is to examine the relative proportions of the various pottery types at various sites to determine if there are meaningful differences in the proportions of ceramic types across the area. Such differences in turn will reflect cultural affiliation and integration. The presented research evaluates the relative abundance of the various pottery types at 76 Draw and ultimately finds that the amount of Ramos polychrome in the assemblage is high relative to other areas in the Medio period world. This in turn reflects social interaction with a southern Ramos Zone centered on Paquimé, Chihuahua, and suggests that at least some Animas Phase sites had a close association with Medio period settlements far to the south.

[338] Catachresis and Catechesis in the Pueblo Missions of 17th Century New Mexico

Building upon recent anthropological critiques of “hybridity,” this paper will critically examine this concept and its companion, “purity,” in archaeological scholarship. I argue that the identification of hybridity can tell us as much about archaeologists’ own biases as it can about the subjects of our research. Using the
theoretical concepts of hybridity developed by Bakhtin, Bhabha, and Latour, this paper examines the material culture of 17th century Franciscan missions in New Mexico. A case study investigates the ways in which Pueblo peoples appropriated and re-purposed “foreign” material culture under Spanish colonialism, with a focus on the Pueblos’ consumption of bells in 17th century contexts.

Wixarika Territoriality and the Production of History

Wixarika (Huichol) placemaking extends mythical-historical symbolism along ancestral paths into new geographic spaces implicated in long-distance exchange through principles of metonymy (direct extension), iconicity (formal resemblance) and synecdoche (hierarchical entailment) that link analogous, often eponymous sites to increasingly encompassing scales of reference. In turn, the appropriation of such places provides topographic referents for transforming and further extending that history in space. I take examples of placemaking from the 90,000 square kilometers encompassed by Wixarika cosmological territory (kiekari). According to other research, kiekari has extended from the Pacific coast to the San Luis Potosí desert in the east, Jalisco lake region (S) and Sierra Madre Occidental of Durango (N) since Classic times. Therefore Wixarika marine and tropical forest resource extraction in the kiekari’s western quadrant, which overlaps the Azatlán region and connotes nocturnal female fecundity, is contextualized via exchange routes that entail complementary products, ecosystems and cosmological values in the desert, a region identified with diurnal male austerity, peyote and turquoise; the lakes (obsidian and rain); and the Sierra’s temperate forests. In this view, Wixarika territoriality employs a metaregional cosmological framework to encompass diverse spaces in discursive and material exchange relationships and to legitimize economic, political and religious hegemony.

Lightfoot, Kent (University of California, Berkeley)

Life at the Margins of Two Colonial Regimes in California

California was the middle ground for two extensive colonial regimes in the late 1700s and early 1800s: the Spanish moving up the coast from western Mexico and Baja California and the Russians sailing down from the North Pacific. As one of the most densely populated areas in North America, thousands of Native Californians were impacted by the subsequent colonial encounters. This paper focuses on those Native people along the frontiers of the Spanish and Russian colonies, and will consider how they forged their politics, social practices, and identities living between two colonial regimes.

Twenty-Five Years with the “Child” and the Archaeology of Childhood

This paper summarizes the main points of my 1989 article, "A Child is Born," relating it to trends in archaeology at the time of publication, and considering its relevance to archaeology in 2014. In an effort to jumpstart debate in archaeology about the potential for an archaeological, historical, and ethnographic study of childhood, the 1989 article attempted to define the child's world generally in time, space, and structure. It applied child's play as an analytical tool towards considering the world of children from an archaeological perspective. Since the publication of this article, its main points have been elaborated, while the "child" has matured itself, as it has contributed to the establishment of the archaeology of childhood as a topic of interest in archaeological research. Meanwhile, technological advancements have improved the abilities of archaeologists to study childhood in the past. This paper reviews these developments, and it advocates a cross-cultural approach to studying the multi-relational child as a new direction in the archaeological study of children and childhood in past societies.

Lilley, Ian (The University of Queensland)

Recent Research in the Loyalty Islands, New Caledonia: Archaeological Science and Community Heritage

This paper discusses the results of a long-term project on Tiga, smallest of the inhabited islands of New Caledonia’s Loyalty Islands. The objective was to conduct a project that developed new scientific knowledge regarding Tiga's place in New Caledonian and Pacific human history in a way that also made sense to local people in terms of their own understandings of and priorities regarding their past. We found success in the form of shared ‘meta-interests’ in the sweep of history, producing a model that aligns
archaeological and local understandings of the past in terms of classes of events and processes, such as
the physical formation and initial peopling of Tiga, the introduction of domesticates, and variations in
population movements to and from the island.

[155] Myth and Memory at a 19th Century Catholic Cemetery

Many of the older cemeteries in the United States carry with them stories, sometimes based on truth and
often based on myth and faulty memory. Dubuque, Iowa's Third Street Cemetery represents one of many
19th century graveyards disrupted by urban expansion and development. The Iowa Office of the State
Archaeologist excavated over 900 burials over the course of a five-year period. During that time we read
newspaper articles and heard testimony from locals about the cemetery’s history and the fate of its
residents. Following the excavations and during the analysis and research, we found that many of the
stories were just that – and we were able to debunk some of the most strongly held of them. Others are
just worth retelling.

[28] Practice, Process, and Social Change in Third Millennium BC Europe: The Role of Collective and
Commingled Burials

To understand the changes in burial traditions between the European Neolithic/Copper Age and the Early
Bronze Age, archaeologists have emphasized the Secondary Products Revolution, development of
metallurgy, rise of elites, and spread of Bell Beakers. This tendency reflects the materialism pervasive in
archaeological thought, in which burials are treated as material expressions of religion or ideology, and
that to explain changes in these realms, one needs to look to economic or sociopolitical conditions.
Burials are, however, not only sites of socially organized human action and labor, they have sensorial
properties; their form, visibility, color, tactile qualities, and smells provoke, engage, and constrain the
bodies, eyes, and minds of individuals and groups. With this in mind, I explore how the practice of
dealing with death - including creating and using collective and commingled burials - may have
contributed toward increasing social differentiation in third millennium BC Europe.

[10] Chert and Obsidian Calibrations for pXRF Based on National and International Standards

Archaeologists have increasingly employed portable x-ray fluorescence (pXRF) instrumentation to
analyze a wide variety of materials. Significant questions remain, however, regarding the reliability and
reproducibility of these data. This research presents our methods to calibrate an Olympus NDT Delta
pXRF instrument using national and international standards. We develop calibrations for chert and
obsidian, which we evaluate by comparing (a) the data we obtain from whole rock and powdered
samples and (b) our pre-calibration and post-calibration results. Our analysis demonstrates that
calibration significantly enhances instrument performance and that factory-set calibrations are not
adequate for archaeological research, as they do not yield reliable and reproducible compositional data.

[326] Archaeology and the Community: Constructing Bridges for Knowledge of the Past in
Kaminaljuyu, Guatemala City

Based on archaeological excavations at Kaminaljuyu mound E-III-5 and educational workshops at the
public school "Delia Luz Gutierrez de Castellanos", this paper explores how children position themselves in
relation to their surroundings and how knowledge of the ancient past and their relationship to it varies when
they are exposed to archaeological excavations. I focus on the perception of the archaeological site of Kaminaljuyu and its relationship to the social and political-educational discourses that are associated with Guatemalan national archaeological projects. The hypothesis is that archaeological sites in Guatemala are used to promote a national identity that encourages tourism consumption of “exotic” ancient Mayas, which is totally disconnected from contemporary Mayan indigenous peoples’ movements and local communities’ interests.

This represents the first systematic study and initial investigation of these issues in the Guatemalan highlands, and I hope that it will serve as a platform for an activist archaeology in Guatemala that looks to socialize the production of archaeological knowledge to those who do not have access to private education, and to continue discussions on challenges of academia for social justice and its impacts on the population.

Lindauer, Owen

[151] A Personal Perspective of 39 Years of Transportation Archaeology: Contributions, Issues, and Challenges

Transportation archeology has been and continues to be if not the most active contributor to archeological research and practice, is among the most active contributors to advancing our discipline over the past 40 years. Development is the reason why there is a continuous demand for responsive, inventive, attentive, and professional archeological efforts. But the nature of “development” exerts its own set of constraints, issues and challenges to conducting archeological investigations and advancing archeological research. This presentation will touch on some of the highlights of transportation archeology from a perspective an individual over the past 39 years.

[198] “Crossroads” through the Caucasus? Autochthonous Political Development on the Margins of Mesopotamia and the Steppe

It has been over 20 years since Phil Kohl penned some of the first English-language summaries of material culture and archaeological periodization in the Caucasus, an area that he alternately referred to in quotation marks as the “frontier” and “periphery” of the Near Eastern world. Kohl’s papers signaled an early attempt to push back against Assyro-centric views of the Caucasus and demonstrate that behind the Iron Curtain lay a rich archaeological landscape derived through historical and social processes independent of—if not entirely disarticulated from—the cities, states, and empires of Mesopotamia. This paper summarizes results of ongoing investigations by Project ArAGATS in Armenia, where research over the past 15 years has uncovered evidence for local pathways to complexity that take us beyond traditional images of the Caucasus as a supplier of raw materials to the Near East and passive receptor of cultural traits that passed between Mesopotamia and the Steppe. Recent excavations in a wide of social contexts—cemeteries, residential complexes, citadels, shrines—are illuminating the unique strategies of governance that fortress-based polities employed to assemble communities of mobile pastoralists under their rule, and reshaping our understanding of ancient power and authority in the Caucasus and throughout Eurasia.

Lindstrom, Katie (University of Wisconsin-Madison)

[35] Patterns of Elite Harappan Pottery in the Indus Civilization Borderlands of Gujarat

Research presented in this paper tests prevailing models about the spatial patterning of Harappan pottery in the Indus Civilization borderland region of Gujarat, where it is found in association with regional non-Harappan pottery at many walled cities and towns. Prevailing models conclude that Harappan pottery was introduced into Gujarat by migrants from the Indus Valley. An untested premise of these models is that Harappan vessels were the only pottery types utilized by elite residents and were restricted to use inside the perimeter wall. In contrast, non-Harappan pottery was utilized by non-elite residents who were forced to live outside the perimeter wall. In this paper I present new pottery data from the walled site of Bagasra, which contradicts prevailing models. These new data establish the spatial distribution of many Harappan pottery types on both sides of Bagasra’s perimeter wall, where they occur in association with a variety of non-Harappan pottery types. Based on these data, I contend that elite residents of Indus settlements in borderland areas utilized both Harappan and regional non-Harappan
pottery. I offer a revised model for the spatial patterning of Harappan pottery in borderland regions, which accounts for their documented distribution at walled settlements.

Ling, Johan and Kristian Kristiansen (Professor)  
[118] Comparative Advantage as Mode of Production in Bronze Age temperate Europe

Control over the exchange of metals was a crucial feature of stratified societies in temperate Europe during the Bronze Age. To obtain the precious metals they needed (such as copper and tin) different societies used different strategies. Environmental, geographical and social differences were used in the development of regional specialization and in the creation of surplus value. Thus, people within various regions focused on amber, tin, gold, copper or textiles. In line with Marxist theory we argue for the hypothesis that certain social relations, geographical positions and environments created comparative advantages that impacted the direction and velocity of the movement of persons, raw materials and finished goods in the Bronze Age.

[21] Intrusive Settlement and Cultural Assimilation Processes in the Sayula basin (Western Mexico) during the Early Postclassic

The Early Postclassic settlement pattern in the Sayula Basin demonstrates two overlapping sociocultural components. On the one hand, the Sayula phase is a well-structured regional development with its own cultural identity within a greater socioeconomic system. On the other hand, some groups affiliated with the Aztatlán sociopolitical system, locally known as Cojumatlan phase, were within distinct kinds of settlements and reflect different stages of incorporation. Both components are represented by two political centers, La Picota for the Sayula phase and La Peña for the Cojumatlan phase. Both are major settlements, separated by a relatively short distance (around 30 km), but characterized by pronounced diversity in the internal settlement pattern, material culture, ritual, and so on. No evidence of confrontation or competition has been noted in the comparative study of both sites, yet by A.D. 1100, a new sociocultural structure emerged, known locally as the Amacueca phase, which shows a steady link with the Cojumatlan phase. The Aztatlán presence in the area might have caused the decline of the Sayula phase following cultural assimilation within the Aztatlán system.

Lipe, William (Washington State University)  
[151] Glen Canyon Salvage to Dolores CRM: Big Projects and Big Changes

The Glen Canyon (GCP) and Dolores (DAP) projects were the largest of their day in the Southwest and are still among the largest archaeological projects ever carried out in the United States. The GCP (1957-1963) was designed and conducted as "emergency salvage", while the DAP (1978-1985) was one of the first large projects to be initiated after "CRM" formally emerged in 1974. Both these efforts were rooted in the archaeological method, theory and practice of their time, but both had aspects that anticipated later developments. And they were designed and carried out in very different legal and public policy environments. Perspectives gained from analyzing these two influential projects will be used to identify and comment on some of the principal trends and transitions that have shaped US public archaeology since the 1950s.

[193] Easter Island, Archaeological Evidence, and the Evolutionary History of Warfare

Reevaluation of existing evidence suggests a remarkable lack of systematic warfare among the prehistoric population of Easter Island. The archaeological record of the island is in marked contrast to other Polynesian islands where violence is well-documented and widespread. The evidence from Easter Island contradicts common assumptions about the island but is consistent with the conditions that favor warfare. Here, we evaluate the evolutionary landscape of systematic violence and show that when retaliation is likely evolutionary stable strategies involving violence avoidance and alternative means of negotiating conflict and competition
become fixed in the population.

[57] Return of the Yumbos: A Cultural Happening in Nanegal, Ecuador

Leaders of the Palmitopamba Archaeology Project in the cloud forest of northwestern Ecuador have worked for years to involve and collaborate with the local mestizo community, but in 2013 the embrace was expanded to include modern-day descendants of the ancient Yumbos. Representatives of the Tsachila and Quichua Quijos indigenous nations were invited back to a portion of their ancestral homeland for public and private events related to the archaeological project. Visits to sacred waterfalls, conversations about local history and other events were coupled with shamanic rituals to consecrate the archaeological sites and to re-bury previously excavated human remains. An overview of this event, which was co-sponsored by the parish government, is given along with some analysis of the process, the results and what the future might hold with regard to the "decolonization" of the archaeological project.

[204] Un estudio del Monolito de Maltrata, Veracruz

El monolito de Maltrata es hasta el momento la única escultura monumental labrada en piedra encontrada en el sitio arqueológico denominado Rincón Brujo ubicado en el periodo Posclásico. Fue trasladada al Museo de Antropología de Xalapa, Veracruz por Alfonso Medellín Zenil en 1962, donde actualmente se encuentra. Su estudio es importante dada la poca presencia de escultura monumental en las altas montañas del estado de Veracruz, México, donde se encuentra enclavado el valle de Maltrata. Diversos investigadores han descrito las escenas que se labraron en la superficie de esta gran piedra, relacionadas posiblemente con un evento político de algún personaje, durante una fecha significativa indicada por el planeta Venus, encontrando semejanzas con símbolos en sitios arqueológicos ubicados en el periodo epiclásico como Xichicalco, Tajín, Cacaxtla, y otros de Teotihuacan y de la zona Maya. En esta ponencia se presenta una analisis de los grabados así como otros elementos arqueológicos encontrados en recorridos de superficie y excavaciones realizados en la ultima década cercanos al monolito, que ayudan a contextualizar en tiempo y espacio la posición del monolito así como una interpretación mas amplia.

[323] A French Outpost in the Mississippi Choctaw Homeland

Recent excavations at 22KE630 revealed the presence of an undocumented eighteenth-century French outpost in Kemper County, Mississippi. Broad areal excavations exposed the archaeological footprints of three French earthfast poteaux en terre structures in association with large assemblages of Choctaw ceramics. Given that most archaeological sites associated with European colonial settlements in the region yield substantial assemblages of Native American ceramics, an immediate question arises as to whether the eighteenth-century site occupants were exclusively Frenchmen, who were obtaining ceramic containers through exchange and interactions with neighboring Choctaw populations, or a mixture of both Frenchmen and Choctaws. The question is further complicated by material evidence of a Choctaw ritual performed at the site, which opens the possibility that the site was occupied simultaneously by both Europeans and Choctaws. This paper accordingly explores evidence pertaining to the identities of the site occupants.

Livesay, Alison (University of Oklahoma)
Archaeologists have conducted much research on Classic Mimbres ceramics (A.D. 1000-1130) in southwest New Mexico. However, there exists a strange oversight of Mimbres bowls fired in an oxidizing environment, in which bonded iron oxides in the paint give it a distinctive reddish color. While still classified as part of the black-on-white design tradition and found in similar mortuary contexts, I argue that these oxidized bowls were intentionally manufactured. The resulting red color and its placement on bowls may be indicative of the symbolic function of these vessels as “visual metaphors” of an Mesoamerican inspired ideology or religion that was present during the Classic Mimbres period.

[311] *New Thoughts on Old Trash: Patterns of Refuse Disposal at El Hatillo/He-4, Panama*
Lithic distribution at the site of El Hatillo/He-4, Panama indicates that Late Ceramic period residents of the village manufactured and disposed of the by-products of manufacture over recently abandoned structures rather than middens. This placed potentially hazardous debitage out of the way of daily activities, rather than left to be swept up periodically along with other refuse. Hayden and Cannon (1983) discuss ethnographic evidence of such behaviors among Highland Maya, noting that members of communities routinely sort refuse by type and discard those types differentially based on economy of effort, value of refuse, and hindrance of refuse (Hayden and Cannon 1983). The gradual accumulation of particular types of refuse in the same areas or spatial contexts across El Hatillo and over the course of multiple generations of residents must have contributed a certain “fabric” to the village to which the all villagers adapted.

Lockau, Laura (McMaster University) and Megan Brickley (McMaster University)
[28] *Bioarchaeological Examination of Commingled Human Remains from the War of 1812: Perimortem Trauma in the Smith’s Knoll Sample from Southern Ontario, Canada*
While underutilized in paleopathological analysis, human remains that are fragmented, disarticulated, and commingled provide valuable evidence for lived experiences of perimortem traumatic injury in the past. These contributions are particularly relevant to samples associated with battle contexts; during warfare, human actions related to interpersonal violence, postmortem treatment, and mass burial increase the likelihood of commingling and fragmentation in assemblages of human remains. This paper will outline the interaction of these processes for the Smith’s Knoll sample from southern Ontario, Canada, a collection containing the remains of soldiers who were killed during the battle of Stoney Creek in the War of 1812. This skeletal assemblage is associated with significant documentary evidence for events that occurred during and following the battle, providing a unique opportunity to examine how skeletal evidence for perimortem traumatic injuries compares to conceptions of injury experience based on historical documentation. Available comparative evidence provides context and indicates what evidence may be missing due to the condition of the remains. Results from bioarchaeological integration of paleopathological and historical data at Smith’s Knoll indicate how fragmentation, disarticulation, and commingling of skeletal remains from a warfare-related context can develop and ultimately affect the evidence available regarding soldiers’ experiences of traumatic injuries.

Lockhart, Jami (Arkansas Archeological Survey)
[30] *More Than Just Remotely Interested: Dr. Tom Green and AAS Geophysics*
In 1998, Dr. Thomas J. Green began authorizing the purchase of a full complement of
archaeogeophysical technologies for use at the Arkansas Archeological Survey. At that time, proof-of-concept projects were scarcer than they are today. These technologies were still commonly regarded with skepticism within mainstream archeology. The mention of geophysical survey potential would often elicit comments akin to “we tried that once, and it didn’t work.” More than 15 years and 150 projects later, the geophysical results presented here are testament to Dr. Green’s foresight, initiative, and support, which have substantively advanced Arkansas archeology. Remote sensing has been used for the discovery of countless cultural features, and has provided insights into intrasite organization at both historic and prehistoric sites in all parts of the State and beyond. Examples of these contributions will be drawn from a variety of projects, site types, cultural affiliations, and physiographic settings.

Lodge, Spencer and Steve Black (Texas State University)  
[316]  Roasting Pits within the Sheep Range in Southern Nevada  
Since early 2012, Google Earth aerial imagery has been used to identify over 200 roasting pits throughout the Sheep Range, on the Desert National Wildlife Refuge in Southern Nevada. Images of these features were ground-truthed and 161 roasting pits were visited where surface observations and measurements were documented. Surveys were also conducted in proximity of each feature to identify additional archaeological elements, such as evidence of habitation. These sites are primarily standalone processing features where most likely a variety of plants (Agave utahensis, Yucca brevola, Yucca schidigera, and Yucca baccata) and other foods were cooked and processed. The total number of artifacts found in association with these features was underwhelming, but preliminary analysis suggests these sites were primarily used within the past 1,000 years. The abundance of these features within the Sheep Range indicates the significant role they played in the prehistory of the area.

[250] Towards a Cultural Biography of Maize in West Africa  
One of Deborah Pearsall’s central contributions was tracing the spread of maize into South America using novel techniques, revealing patterns that had previously been invisible, and opening the doors to new debates and understandings about the past. Using this single commodity approach, I examine the adoption and spread of maize in West Africa using archaeobotanical, archaeological, and historical data from Ghana. I offer a cultural biography of maize as its use changed through time and over space, from its initial adoption as a luxury crop, to its commoditization during the Atlantic slave trade, and ultimately its role as a stop gap crop during times of food shortage during the colonial period.

Lohse, Jon (Gault School for Archaeological Research)  
[280] Dating Calf Creek Bison in Texas  
This paper presents the results of ongoing AMS radiocarbon analysis of bison remains recovered from Calf Creek or probable Calf Creek components in Texas. Dating Calf Creek has been challenging in most regions where this horizon is found. Modified XAD pretreatment of archaeological samples is adding considerable resolution to our understanding of when this horizon occurred. We present a record of approximately 20 dates from five sites, and discuss what this means for the early Middle Holocene record of the Southern Plains.

Lombardo, Umberto (Institute of Geography, Bern, Switzerland), José M. Capriles (Center for Comparative Archaeology, University of ) and Heinz Veit (Institute of Geography, Bern, Switzerland)  
[69] The Paleoenvironments and Adaptive Strategies of the first Amazonian Hunter-Gatherers  
Until recently, very little was known about the early human peopling of central South America and the interior Amazon basin. Here we report on early Holocene archaeological sites, mostly shell middens, located under forest islands (patches of forest surrounded by savannah) in the Bolivian Llanos de Moxos. Two of these sites: “Isla del Tesoro” and “San Pablo” are compared. Geoarchaeological survey permits reconstructing the paleoenvironmental context of these two sites. Furthermore, differences in the archaeological record, unveiled during archaeological excavations, provide new data for discussing the nature of human-environment interactions and the adaptive strategies of the first Amazonian hunter-gatherers.

Longstaff, Laura (University of Idaho) and Robert Lee Sappington (University of Idaho)  
[343] The Kelly Forks Work Center Site, North Central Idaho: 12,000 Years of Occupation at the Interface between the Columbia Plateau and the Northwestern Plains  
The Kelly Forks Work Center site (10CW34) is located at the confluence of Kelly Creek and the North Fork of the Clearwater River on the Clearwater National Forest. Archaeological investigations began here in 1969 and occasional small-scale surveys and testing projects were conducted until University of Idaho archaeologists conducted data recovery excavations from 2010 to 2012. A series of 26 radiocarbon dates, beginning at ca. 10,680 BP (Cal BP 12,820), documented a series of recurring occupations from the Western Stemmed Point Tradition (Windust phase) into the historic period. While most cultural materials are comparable to those from the southern Columbia Plateau, lithic tools similar to styles from the northwestern Plains, including a Paleoindian Goshen point and late prehistoric Avonlea points, were also recovered. Onsite activities included tool manufacture and modification, fishing, hunting, and animal processing. Faunal remains were minimal but protein residue analysis on lithic tools identified bison, sheep, dog, rabbit, rat, beaver/porcupine, rat, human, and other antisera. X-ray fluorescence identified obsidian and vitrophyre tools and debitage from multiple sources in Montana, Idaho, and Oregon. Kelly Forks represents a significant setting in the northern Rockies that was used intermittently for more than 12,000 years.

Creating and Recreating a Myth: Inca Ritual and Administrative Centers along the Pilgrimage Route in the Peninsula of Copacabana, Bolivia

Spanish chronicles claim that the sovereign Inca Yupanqui transformed the town of Copacabana on Lake Titicaca into an important administrative center with the settlement of a significant number of members of the elite Inca lineages or panacas. The construction of temples, storehouses (colcas), pilgrims’ lodgings (tambos or corpaguasi), shrines, roads, and carvings of the living rock throughout the peninsula of Copacabana are observable, in part, to this day. The purpose of such substantial efforts was to attend the requirements of the numerous pilgrims that visited the region on their way to the sacred rock, birthplace of all nations, located on the Island of the Sun. The Incas also displaced and resettled the local inhabitants and repopulated the region, bringing people from 42 different ethnicities as colonists or mitimaes. This paper explores the massive changes wrought on the physical landscape by these construction projects.

López Bravo, Roberto (Universidad de Ciencias y Artes de Chiapas) and Elizabeth Paris (University of Southern Mississippi)

Maintaining the Western Maya Frontier: Highland Chiapas in the Early Postclassic Period

This paper examines the multifaceted ways that social identities were constructed and expressed in highland Chiapas during the Early Postclassic period. This region formed part of the western frontier of the Maya linguistic and cultural area, and thus provides a valuable perspective on the ways that the occupants of this area used material culture to define their relationships with their non-Maya neighbors. Ethnohistorical records also suggest that the Maya residents of this area had a highly tense and antagonistic at Spanish Contact, particularly with the Chiapanecs of the Central Depression of Chiapas, who are thought to have immigrated to the area near the end of the Late Classic period. Archaeological data can clarify the degree and nature of the contact between these groups, and the degree of porosity in spatial and social boundaries. Excavations at Moxviquil and Huitepec suggest that previous economic exchanges with likely Zapotec-speaking populations during the Late Classic period were discontinued during the Early Postclassic period, indicating that the porosity of the western frontier decreased. While there is no archaeological evidence for violent conflict along the border, the defensible locations of these sites testify to uneasy political and social relationships during these periods.

El discurso político versus las esferas no elites: cambios en las dinámicas de interacción en el valle poblano-tlaxcalteca

Tradicionalmente se considera que los cambios del Epiplíasico (600-900 d.C.) al Posclásico (900/1000-1519 d.C.) en el Valle de Puebla-Tlaxcala conllevaron varios procesos sociales entre los que destacan importantes migraciones, conquistas, conflictos interregionales, y la propagación de pequeñas entidades estatales rivales, entre otros. Estos procesos generalmente son estudiados a través de manifestaciones de poder asociadas a los sectores gobernantes. Sin embargo, la cultura material de los grupos no-élite de la sociedad no necesariamente refleja estas condiciones de manera evidente. En este trabajo hablaremos de la interacción social entre las esferas no-élite de algunos de los principales asentamientos de la región poblano-tlaxcalteca, comparando su cultura material y la incidencia de materiales foráneos en los distintos sitios del valle.

Las figuras huecas en la tradición Teuchitlán del centro de Jalisco: ritualidad e identidad social

Las representaciones antropomorfas son abundantes entre las ofrendas funerarias de la tradición de tumbas de tiro en el centro de Jalisco, entre 200 a.C. a 400 d.C. Sin embargo, no se ha realizado un análisis antropológico sistemático de las mismas, a partir de sus contextos de producción, distribución, uso y deposición, especialmente porque en dichas figuras se plasmó la cosmovisión e ideología de la elite dominante, convirtiéndose en imágenes performativas que proyectaron los valores sociales y los sistemas simbólicos en la subjetividad de los individuos mediante los diferentes códigos que las conforman, es decir, que los conceptos y categorías que organizan el conocimiento son directa o indirectamente corporalizados en ellas; de ahí que, a partir de estas representaciones antropomorfas es posible analizar cómo las prácticas sociales estructuran el cuerpo y sus representaciones, construyendo seres sociales vía la internalización de esquemas y valores básicos, al igual que el papel del ritual en este proceso.

Preliminary Excavations of Structures B6 and B7 at Cahal Pech, Belize

During the 2013 field season, preliminary excavations on Structure B6 and B7 at Cahal Pech were conducted by students from the American Foreign Academic Research program with the Belize Valley Archaeological Reconnaissance. The excavations extended 53 meters horizontally in an attempt to examine the Late Classic period architecture on both range structures. The building platform was uncovered and extended across both structures, offering a better understanding regarding the structural transition of the two buildings. The location of structures B6 and B7 in the less-restrictive and public Plaza B infers possible functionality. However, the interior side staircase on structure B7 could infer limited access. The information presented in this paper is effective in understanding how Plaza B functioned during the Classic Period.
“These Names,” She Said, “These People, Are Our Road Signs.” Social Obligations, Toponymy, and Wayfinding in the Barrenlands of Northern Canada.

The lives of the Innu of Nitassinan (interior Labrador) and the Inuit of Nunatsiavut (northern Labrador) share with their ancestors an extraordinary ability to thrive in a challenging tundra and taiga landscape despite widely dispersed group aggregates and very low population densities. Strategies to access local, as well as non-local, resources and maintain far-flung social networks are integral to the survival of northern peoples. This presentation considers ethnographic accounts and historical observations, as well as archaeological remains including quarry sites, portage and travel routes and boulder features, to interpret hunter-gatherer mobility and knowledge about landscapes.

Losey, Ashley
[23] Risk and Climate at High Altitude, a Z-score Model Case Study from Wyoming’s Wind River Range

High Rise Village in Wyoming’s Wind River Range is one of several anomalous large high altitude habitation sites in North America. The site’s climatically sensitive treeline setting presents an opportunity to explore the role climate may have played in its occupation. This study considers climate-driven resource variability and models how foragers could have handled the risk of subsistence shortfall under two climate regimes, stable and variable. The z-score model was used to generate risk-minimizing foraging expectations under the different climate scenarios. Further, an onsite dendroclimatological study generated a highly localized, nearly millennium deep climate reconstruction for the site to characterize periods of relative climatic stability and variability.

[53] Identifying Sled Dogs through Bone Functional Adaptation Studies

Sled dogs were critical elements of many northern societies. Despite their importance, there have been very few attempts in archaeology to differentiate sled dog skeletons from those of other dogs. Working with skeletons from canids with known life histories, including Inuit sled dogs, modern house dogs, and northern wolves, we attempt to demonstrate how the shapes of limb bones of these animals vary in relationship to activity patterns. Recent studies have demonstrated that limb bone cross-sections and overall shape are related to the strains placed upon the limb during life. In this study, we utilize computed tomography (CT) scans of canid limb elements to analyze and compare their shapes and sizes. We predict that the limb elements of sled dogs will be more robust than those of sedentary dogs, as bone will in part remodel in accordance with the strain it experiences. Wolf limb elements also should be robust because these animals are highly active and their limbs experience high levels of variable strain. Although both wild northern wolves and sled dogs are highly active, we predict that the specific activity of sled pulling produces a strain pattern that distinguishes the cortical bone geometry of sled dogs from other canids.

[211] Coupling Lithic Sourcing with Least Cost Path Analysis to Model Paleoindian Pathways in the Far Northeast

Studies of prehistoric lithic source areas traditionally focus on geologic sourcing, mining methods, and/or stone tool technology. Where direct procurement of toolstone can be inferred, complementary GIS terrain analysis can provide insights on movements of prehistoric human groups after toolstone acquisition. Researchers of North American Paleoindians have used GIS least cost path analysis (LCP) most commonly to reconstruct possible routes for regional and continental colonization, but this approach can also help infer post-colonization seasonal movements. In the Hudson Valley of New York, Paleoindian fluted point groups heavily exploited Normanskill chert outcrops during the late Pleistocene, as demonstrated by our sourcing studies of geologic and archaeological specimens using X-ray fluorescence (XRF). We combine (1) XRF sourcing results that link Paleoindian sites to Hudson Valley/Normanskill chert outcrops, with (2) regional LCP analysis, to model seasonal pathways of Paleoindian groups in the Far Northeast.

Loubser, Johannes (Stratum Unlimited, LLC)
Seven Millennia of Visitation to the Watson Petroglyph Complex, Southeast Oregon

Markings that qualify as petroglyphs were positively identified on 284 panels within the Watson Complex. At least the following five traditions were observed within the complex: the Great Basin Abstract Tradition; the Columbia Plateau Tradition; the Interior Line Tradition; the Hunting Tradition; and the Plains Ceremonial Shield Tradition. These traditions most likely span a period from at least 5000 BC to AD 1850. Among the 10 test units excavated near petroglyph boulders, the exposure of Mount Mazama tephra and recovery of two Middle Archaic point fragments suggest that site use extended back to 5000 BC. Recovery of a Rosegate series point and a brown ware ceramic bowl fragment shows that Native American site use continued into proto-historic times. Flakes and river pebbles that were found wedged within cracks of boulders near petroglyph surfaces are physical testimonies of ritualized actions.

The Impact of Climate Change on Dietary Choice during the Holocene at North Creek Shelter, Utah

A common assumption in the Basin-Plateau region is that dietary shifts among plant and animal resources with different energy returns were driven by climate change. Effective testing of this assumption requires an understanding of the relative importance of economic plant and animal resources through time and space. As such, we would expect to observe in the archaeological record evidence for flexible and dynamic subsistence strategies developed to cope with climate change. North Creek Shelter, a stratified archaeological site in the arid Northern Colorado Plateau provides a unique opportunity to investigate changes in diet breadth from the early to middle Holocene, a time of significant climatic variability. Multidisciplinary approaches to investigation of the archaeological record at North Creek Shelter has included studies of macro- (seeds, fruits, leaves) and micro-botanical (pollen, tuber starch grains) remains adhering to ground stone surfaces, hearth features, and rockshelter sediments. Together with independently generated vertebrate faunal data we can test the notion of climate driven subsistence shifts from a foraging theory perspective.

Reconciling Function and Use – Reassessing the Role of Maya Ceramic Types through Empirical Analysis.

The function of certain categories of Classic Maya vessels has long been assessed by formal characteristics, iconographic and textual references, and ethnographic analogies. An empirical analysis of a significant sample of such vessels, however, showed that content residues and technical capabilities of the vessels did not and could not match such presumed uses. In order to reconcile this conflict of interpretation and data, it became necessary to reexamine the typology and methods of vessel classification. Ultimately, the theoretical framework challenged how concepts such as ‘use’, ‘function’, and ‘role’ relate to actual ancient behavior and the artifacts by and through which such behaviors were performed. The resulting reassessment revealed broad implications for our understanding not only of these vessels, but also significant implications regarding the ritual and political institutions of Classic Maya elites.

The Early Mesoamerican City: An Introduction

Mesoamerica was a land of cities, and the key trait that distinguishes Mesoamerica as a cultural region in comparison to the zones north and south of it is the presence of cities. The first generation of Mesoamerican cities was formed in the Formative or Preclassic era, as populations aggregated in settlements that were political, economic, and ritually prominent. In the functional sense of urban centers as central places, cities were present in the Early Formative, and in the Middle to Late Formative period cities reached a scale that matched or exceeded those considered to be urban in other parts of the world. By the Late Formative urban settlements were present in all of Mesoamerica, linked by economic exchanges as well as cultural exchanges, especially marked by the creation of a high culture that cut across ethnic and linguistic boundaries. This paper considers the nature of early cities in Mesoamerica, the links that united them, and the role that theories of urbanism and urbanization can play in the analysis
of Formative-period Mesoamerica. It will also examine the distinctive nature of first-generation cities, and the role that Mesoamerica can play in constructing theories of early urban settlements around the world.

[144] Subsistence Patterns during the Casas Grandes Medio Period: Results of the Faunal Analyses from Sites 315 and 355.

Sites 315 and 355 were small agricultural villages occupied during the Casas Grandes Medio period (1200 - 1450 A.D.), and located in close proximity to Paquime, in northwest Chihuahua, Mexico. The faunal analyses of the assemblages from both sites produced contrasting results. The Site 315 assemblage was dominated by jackrabbits and other small mammals, whereas the Site 355 assemblage was comprised predominantly of larger mammals, with a much greater ratio of cottontails to jackrabbits than at Site 315. The extreme difference in the Lagomorph Index, the Artiodactyl Index, and the overall ratio of small to large mammals between the faunal assemblages recovered from the two sites suggests either a change in the local environment, resulting in an increase in the relative abundance of particular species of animals, or differences in the hunting strategies utilized by the occupants of the two sites. Differences in environment and species abundance may indicate that the sites were being occupied at different times, with Site 355's occupation likely occurring later in the Medio period than Site 315.

[73] Landscape Marking and Network Maintenance in Big Rough Spaces with Few People: “It’s Dangerous to Travel Alone”

Many aspects of hunter-gatherer network dynamics are strained in circumstances where low population densities are coupled with large spaces and where mobility is difficult. Since all individuals are critical components of such small scale systems, knowledge of member movements and locations, and practices designed to minimize individual loss, figure prominently in network preservation. This goal is facilitated by landscape marking behavior. Here, the practical aspects of network dynamics in such contexts are explored through a case study employing the cumulative regional ethnography of the Innu/Naskapi of Labrador.

[253] Nondestructive Analysis of the Lithic Artifacts from Chiapa de Corzo

Archaeological excavations at Chiapa de Corzo have provided important information on funerary and ceremonial contexts dating back to Middle Formative period. In order to understand the provenance and probable trade routes of the imported lithic objects, such as jade, serpentine, obsidian and iron ores, an important sample has been analyzed with nondestructive techniques. Combined information from Infrared Spectroscopy FTIR, Raman Spectroscopy and X Ray Fluorescence has allowed us to identify their elemental composition and probable sources, thus representing a solid advance on the understanding of early interaction networks in southern Mesoamerica.

Lowe, John (Texas Parks and Wildlife)

[258] Building a Community of Archaeologists through Social Media

More agencies, cultural resources management firms, and individual archaeologists are now using social media for promotion and outreach. However, the use of microblogging platforms such as Twitter and Instagram can also help in building a “community of archaeologists” that goes beyond typical job networking. This community aspect is likely just as important, particularly for younger working archaeologists and those still in school. People can commiserate, seek support, share advice and suggestions, and forge friendships outside of a professional setting and beyond the field. It is also a way for archaeologists to join forces to discuss and act on serious issues affecting them, such as the recent
fight concerning the use of volunteers and unpaid interns, known as #freearchaeology.

Microblogging also allows for a different perspective from the common top-down, expert, official narrative. Field and lab techs are able to share their photos and their opinions. Finally, it gives the public a glimpse into the daily lives of archaeologists and the challenges we face, in essence adding a different element of "humanity" to archaeology.

Lowery, Darrin

[114] Geoarchaeology and Paleo-American Prehistory: The Middle Atlantic Delmarva Peninsula Data

Both soil science and geology play a crucial role in trying to locate pre-13,500 year old archeological deposits. Over two decades of fieldwork, testing, and interdisciplinary collaboration have resulted in a detailed understanding of both the upland stratigraphy and the relative sea level record of the Delmarva Peninsula region. Data from Paw Paw Cove, Mockhorn Island, Miles Point, Oyster Cove, Cator’s Cove, Elliott's Island, and Parson’s Island have provided us with a comprehensive understanding of climate driven upland landscape formation processes. Three of the sites have revealed Clovis-age archaeological deposits, which provide us with a glimpse into the Younger Dryas influence on the region. Four sites hint at an LGM-age human presence dated to circa 27,500 calBP to 23,000 calBP. Recognizing the controversial nature of these claims, the Delmarva Peninsula archaeological data could represent an early attempt to colonize the Americas. Regardless, the research clearly shows the value of focused regional geoarchaeological syntheses in trying to locate Paleo-American archaeological sites and deposits.

[153] Chiquilistagua Archaeology Project First Season Findings

The 2013 season at Chiquilistagua archaeological project was the first year of a multiple year research program intended to survey and describe archaeological sites west of Managua. The site of Chiquilistagua was chosen as the first location because of its proximity to potential trade networks. Materials have been found in this year’s excavation that may point to lithic production. This paper will present data from the 2013 excavation season as well as some new interpretations about cultural diversity within Nicaragua.

[196] Ground-penetrating Radar as a Tool for Large Cemetery Management

Large cemeteries used over long periods of time present complex management concerns to both those charged with maintaining the cemetery and organizations involved in construction on their periphery. These cemeteries are commonly mismarked and boundaries are often unknown. Ground-penetrating radar (GPR) is often used to identify the location of burials and define cemetery boundaries. GPR surveys are an invaluable tool in situations where a diverse group of stake holders are trying to efficiently assess the situation, understand the cemetery, and, in cases where disturbance may be necessary, evaluate their options. Large surveys, however, require specific methodological steps to both organize data and expedite processing. In this paper, we will discuss strategies we use for approaching large and complex cemeteries using examples from cemetery surveys in North America. We will also discuss varying goals for cemetery GPR surveys and how our approach can vary based on client needs.

[203] Middle Horizon Funerary Traditions among the Ramadas in the Vitor Valley of Southern Peru

Recent multidisciplinary research in the Vitor Valley of southern Peru conducted through the Vitor Archaeological Project offers compelling archaeological evidence of Wari direct intervention in Millo and close interaction with the local Ramadas tradition. Wari influence has been identified within the domestic sphere; however, Ramadas mortuary contexts demonstrate minimal impact from this expanding highland society. In this paper we present the results of our systematic excavation of a Ramadas cemetery, and contrast our findings with Wari mortuary patterns documented in Millo, and other prominent Wari-
influenced sites in the region. Specifically, Ramada burials were found within bounded cemeteries distributed along the Vitor drainage. Tomb construction conformed to the deep boot-shaped designs and commonly contained multiple individuals. We argue that the Ramadas identity was not fully transformed by the Wari, and that their funerary practices remained largely unaltered in spite of the fact that the Vitor Valley of southern Peru was central to the Wari highland administration.

New Perspectives on Ancient Maya Trade: Educating the Public through the Museum’s Collection

This paper has two main objectives: first, to present new perspectives on ancient Maya trade from museum collections, and secondly to demonstrate how to educate the public regarding information contained in museum collections. The iconographic analysis of several museum pieces from the Los Angeles County Museum of Art reveals various ways trade occurred within the Maya area. The first analysis was of a set of Maya incense burner stands with imported Maya blue pigment. The second analysis focuses on a Maya vessel's carved image, which notes the gift giving of the valued quetzal plumage between two Maya kings that aided in developing social and political relationships. The third analysis is of a pair of quatrefoil-shaped earrings, which illuminates the constant exchange of ideas such as world view and cosmic order. Museums’ collections are valuable and informative but often stay dormant as pieces sit in galleries without much exposure to the public. The above-mentioned museum pieces are the basis for a museum education outreach program called “The Maya Mobile” from the Los Angeles County Museum of Art. “The Maya Mobile” is a program that educates 2,500 public school students a year on new perspectives of ancient Maya trade.

Lozny, Ludomir

Societal Dynamics of the North Central European Plains, 600-900 C.E.

This paper attempts to explain the transition from non-complex societies to supra-tribal polities in the North Central European Plains between 600 and 900 C.E. The analytical framework for social dynamics in the NCEP 600-900 C.E. involves the process of culture change amplified in the 700-800s C.E. by the reign of Charlemagne and political pressure from the Norse and Carolingian-controlled Great Moravia. Such conditions of political circumscription caused the emergence of a region-wide non-state dissipative polity identified here as the region-wide and Carolingian-inspired Tornow Interaction Sphere (TIS), which declined after the fall of the Carolingian Empire. In result the western parts of the TIS were incorporated into the Ottonian Holy Roman Empire of the 900s C.E., while the post-TIS integrative processes occurring in the eastern part of the region allowed for the emergence of a new state-level polity in the 1000s C.E.. I thus argue that in the seeming absence of critical internal economic and political stimuli, a combination of such causal events as population pressure, warfare, and social circumscription triggered the emergence of the multi-agent polity of the TIS, which subsequently contributed to the rise of a state level polity of the 900s-1000s C.E.

Sound as Artifact

Archaeology is the scientific study of lost civilizations through examination of their physical remains. But sound is ephemeral. So how can it be considered a physical remain, or artifact? Stones and bones - the best known artifacts – persist in the archaeological record. Sound can inhere in architecture which is an accepted part of that record. Such sound may qualify as artifact. An example is the chirped echo discovered at staircases of the temple of Kukulkan at Chichen Itza, Mexico. The chirped echo matches sound of the quetzal - a bird with important cultural meanings throughout Mesoamerica (e.g., in feathered serpent myths.) Probably all ancient pyramid staircases produced impressive echoes when new or maintained by re-plastering. Echoes become fainter or inaudible as staircases deteriorate with time. Restoring the original staircase can restore the original sound. Sound as artifact can also arise from a sound’s cognitive meaning because of the human propensity to associate sound with spirits. Kings and priests were likely motivated to manipulate sound at sacred sites to impress the laity and to secure priestly tenure. (Think of the Wizard of Oz.) Archaeologists should recognize that sound was more important in ancient times when the world was quieter.
Lucas, Virginia (University of Alabama at Birmingham)

[206] Malabar Period Faunal Use at Three Sites in Brevard County, Florida
Three Malabar Period Sites, Hunter’s Camp (8BR2508), Palm Hammock (8BR2509), and Xavier’s Knoll (8BR2510), have been excavated in the Fox Lake Sanctuary in Brevard County, Florida. Faunal assemblages recovered from general excavation units and features were examined to learn more about Malabar Period subsistence. Sampling methods utilized at the site allowed for a more complete perspective on subsistence strategies. The main objectives of this study were to determine the seasonality of the sites and to compare the subsistence strategies between the three sites by determining species diversity, the relative abundance of marine vs. freshwater species and aquatic vs. terrestrial species. The data collected suggests that the people of these sites incorporated turtle and both marine and freshwater species of fish and shellfish, almost to the exclusion of all other species, into the subsistence economy.

[96] Considering the Possibilities: Cultural Resource Management’s Role in Heritage Education
Most of the archaeological work being conducted today is in a cultural resource management (CRM) or public archaeology context. The many successful heritage education programs developed by industry firms demonstrate the possibilities for engaging the public. Schedule and budgetary constraints challenge the average project yet the goal is consistent — to develop public outreach and educational components for our projects that result in a meaningful experience for all participants. But, how does CRM continue to engage the public? This paper explores CRM’s continuing role in heritage education and looks at the potential of everyday technology to enrich our conversations with the public.

Lukach, Katharine (Brandeis University)

The art history of Maya pectoral ornaments and their symbolic meanings in the context of Maya society, religion, and conceptions of the body have been elucidated by scholars including Tatiana Proskouriakoff, Stephen Houston, David Stuart, and Karl Taube. We identify long-term stases and trajectories of change in the representation of these objects from the Late Preclassic to the Late Postclassic periods of Maya culture history. We then connect these representational patterns to archaeological reality, interrogating the archaeological record for physical examples of necklaces and pectoral ornaments and investigating production techniques. Excavation and art history provide two incomplete but complementary sources of information about a body of artifacts that were important to ancient Maya concepts of social status and physical vitality.

Luke, Matthew (Georgia Southern University)

[76] Interactive Interpretative Technologies
As smartphones, touchscreen displays, and other interactive technologies increasingly become part of everyday life, these technologies can provide archaeologists with the opportunity to present the public with a more thorough and engaging interpretation of their work than was feasible in the past. While the information presented on two dimensional textual and image based interpretative signage commonly employed at sites and museums today is limited due to size and number of signs, smartphones and interactive displays can present virtually and unlimited amount of information via an internet connection. These devices also provide researchers with the ability to present their data in image, audio, video, and 3D multimedia formats creating a more engaging experience for visitors to the site. The development and implementation of this technology can lead to more widespread public interest and engagement in support of archaeological research and cultural preservation. This presentation seeks to demonstrate the capabilities of these technologies to enhance archaeological interpretation.

*Mapping Community Organization in the Georgia Piedmont: The View from a Transitional Late Woodland-Early Mississippian Village*

Renewed excavations and geophysical survey at the Raccoon Ridge site in Morgan County, Georgia, began with the premise that our limited knowledge of Terminal Late Woodland and Early Mississippian communities constrains our understandings of the cultural frameworks that gave rise to complex organizational structures in the Mississippian period. In the summer of 2013 the University of Georgia archaeological field school conducted a combination of archaeological and geophysical survey and excavations at Raccoon Ridge. We employed a combination of controlled surface collection, shovel testing, magnetic susceptibility testing, and mapping of soil profiles and phosphate signatures in order to identify areas of potential precontact settlement remains and to identify areas for excavation. Our investigations produced evidence for multiple occupational loci including midden deposits and a combination of Vining and Woodstock phase ceramics, in addition to earlier Archaic and later Lamar phase components. Our results provide initial insights into local variability in the Late Woodland-Early Mississippian transition in the Georgia Piedmont and an evaluation of the specific methods used vis-à-vis the goals of the project.

*Land-Use and Landscape Features among Foragers and Farmers in the Northeastern Congo Basin*

Forested regions of the Congo Basin are occupied by ethnically distinct but interacting populations of foragers and farmers. The interrelationships between forest foragers and farmers are complex and multidimensional and extend to land use rights and patterns reflected by artificial and natural landscape features. In this paper we discuss differences between foragers and famers in how landscapes are viewed, demarcated and used. We also discuss how long-standing sociopolitical inequalities between these populations gave rise to and continue to maintain existing land-use patterns.

Luther, Joseph [14]  
*The Boneyard: A 12,000 Year History*

The Boneyard is a prehistoric and historic site in western Kerr County, Texas. Recent archaeological investigations have revealed an occupation area with diagnostic artifacts dating as early as 12,000+ years BP, and evidence indicates that the site was continuously occupied through the twentieth century A.D. There are two site numbers associated with the site, one (41KR22) associated with an area on a floodplain, and the other (41KR727) associated with a Pleistocene ground surface on a 60-foot-tall bluff overlooking 41KR22. More than 2500 artifacts have been recovered at the site, with most Paleoindian artifacts from 41KR727. Diagnostic artifacts include Clovis, Angostura, Abasolo, Martindale, Pedernales, and Perdiz points, among others. Documentary and archaeological evidence indicate that a great Native American trade fair was hosted by El Mocho, the Tonkawa chief, on this site in November and December of 1782. More than 2000 Indians participated in this event, and they consumed more than 4000 head of beef over two months, thus the name, "Boneyard." The site was occupied by Lipan Apaches from 1700 to 1878, and battles involving Spanish soldiers, Texas Rangers, the U.S. Army, and Anglo-American settlers took place at this site.

Luthern, Megan (Temple University) [257]  
*Examining the Bioarchaeological Potential of Iraqi Kurdistan*

There is tremendous unrealized research potential for bioarchaeological analyses in ancient Iraqi Kurdistan. Excavations at Satu Qala were conducted by the University of Leiden in cooperation with Salahaddin and Leipzig Universities. A total of twelve human skeletons were recovered from these excavations. This paper discusses the bioarchaeological analyses of these human skeletal remains, and examines evidence of health and activity patterns gleaned from this modest assemblage. This pilot study
provides examples of the kinds of informative data that can be drawn from skeletal remains, which in turn build upon and supplement other archaeological methods of inquiry. Despite the small sample size recovered from these preliminary excavations, this paper argues bioarchaeological analyses are an important avenue of investigation, especially in Iraqi Kurdistan, a region that has recently seen a reinvigoration of archaeological research. These bioarchaeological data can greatly enrich this renewed wave of archaeology in the region.

[120]  *Painted Performances in Northern Maya Mural Painting*
The archaeologist Roman Piria Chan recorded the mural paintings of Mulchic, a small Puuc site in northwestern Yucatan, in 1964. In his first descriptions the paintings' use of a clearly delineated compositional space and three-quarter life-size figures immediately recalled the paintings of Bonampak writ small. Despite their smaller scale--the program wraps around the interior of a small single-room temple--the images relate an intricate, multi-part ritual, whose protagonists wrestle, dance and slay each other against a shifting landscape. This paper will examine how the painters used the existing architectural framework to parse the narrative into discrete episodes and distinguish between ritual fields. The viewer becomes witness to and participant in the sanctification of the space.

Lycett, Stephen (University of Kent)

[26]  *Levallois: Looking Back with Forward Planning*
The study of Levallois artefacts (e.g. flakes and cores) has been an important topic within Palaeolithic archaeology for more than a century. Studies of these artefacts have been implicated in major debates concerning cognitive and behavioural aspects of evolution in hominins. This paper will take a look at some key aspects of research into Levallois with an aim of identifying future research priorities and questions. It will also review how three different research strategies – artifact studies, experiments, and mathematical modelling – previously used to investigate Levallois might better be integrated. It is contended that future exploitation of the concepts of “internal validity” and “external validity”, which are possessed by these contrasting data sources to varying degrees, is vital to the integration of these different research threads. By emphasising both the strengths, but also the weaknesses of these different avenues of enquiry, these validity concepts may enable a better sense of how the links between them can be strengthened in archaeological enquiry.

[141]  *Turkey Gizzard Stones: Ecofact, Artifact and Archaeological Curiosity*
Archaeological assemblages in the American Southwest often include turkey gizzard stones, but what do they mean? How can archaeologists learn form this small, colorful but durable ecofact; this recycled lithic artifact or potsherd? How do they function in the living turkey and how do they enter the archaeological record? Identification and context are the keys to accurate interpretation. This long term study of modern wild turkey gizzard stones and clusters from archaeological turkey burials attempts to characterize the normal ranges of variation and add value to the interpretative process. Where turkeys were kept
prehistorically, gizzard stones can help inform archaeologists about cultural and agricultural practices. Even when preservation is not good, gizzard stones are clear evidence of ancient turkeys.

Lyman, R. (University of Missouri Co)  
[286] The History of MNI in North American Zooarchaeology  
North American zooarchaeologists' use of the minimum number of individuals (MNI) quantitative unit began early in the twentieth century, well prior to the discipline’s received wisdom that Theodore White introduced it. MNI’s popularity grew in the 1960s as a result of White’s innovative technique for estimating meat weight and his clear demonstration (if not explanation) of how to determine MNI values from tallies of particular skeletal parts (e.g., left distal humerus). MNI’s popularity faded in the 1980s and 1990s once its flaws were perceived to exceed those of NISP and it was demonstrated statistically that NISP often provided equivalent data.

Lynch, Joshua (Center for the Study of the First Americans) and Jim Wiederhold (Center for the Study of the First Americans)  
[217] Experimental Testing of Composite Points, a Pilot Study  
Microblade technology, and implicitly composite point technology, is present across Beringia from the late Pleistocene through the late Holocene. The roles of microblade technology in late Pleistocene/early Holocene Alaskan archaeological assemblages are much debated, but are essential to our understanding of the past. In this paper we investigate composite point technology through actualistic, experimental testing. We present a small scale pilot experiment conducted with replicated composite points made from caribou antler inset with retouched obsidian microblades, similar to those seen in the archeological record of Alaska and Siberia. The points were mounted to atlatl darts and launched into actualistic targets until each point was rendered unusable. Osseous and lithic components of the points were examined for macro- and microscopic use wear. Results are yielding insight into the functional performance and durability of composite dart points. Future directions of this research are also discussed.

Lynch, Sally (McMaster University)  
[219] Feasting and Power at the Moche Site of Huaca Colorada, Jequetepeque Valley, Peru  
Huaca Colorada is a Late Moche (AD 500 – 800) ceremonial center located in the Jequetepeque Valley on the North Coast of Peru. The Late Moche period was characterized by environmental, religious and political changes. Recent evidence suggests that Moche subjects navigated the dynamic Late Moche period through a political economy predicated on ceremonial feasting. In this paper I discuss my analysis of 5908 ceramics from this site. Previous researchers have suggested that the ubiquitous utilitarian cooking vessels and high quality “tableware” in middens surrounding the elite ceremonial precincts are suggestive of feasting patterns. I use chi-square statistical assays to test the significance of the observed distribution of ceramic forms between the elite and commoner sectors. From this data, I argue that distinct modes of commensalism, in particular patron-role and diacritical feasts, mediated a series of diverse political relationships and materialized varied and likely changing religious roles, social identities, and positions of authority at the site.

[82] Hopewell Ceremonial Landscapes of Ohio  
During the first five centuries of the Christian era, a remarkable society built a large and elaborate complex of earthen mounds, walls, ditches and ponds in the southern flowing drainages of the Ohio River Valley. The number, size, and variety of forms make them some of the most impressive earthworks in all of North America. The period from c. 200 BC to c. AD 500 (Early to Middle Woodland) witnessed the construction of earthen landscape features covering dozen of hectares at many sites and hundred of hectares at some. The development of the vast Hopewell Culture earthwork complexes such as those at Mound City, Hopewell, Fort Ancient and the Newark earthworks was accompanied by the establishment of wide-ranging cultural contacts reflected in the movement of exotic and strikingly beautiful artifacts such as elaborate tobacco pipes, obsidian and chert spearheads, copper axes and regalia, animal figurines and delicately carved sheets of mica. These phenomena, coupled with complex
burial rituals, indicate the emergence of a powerful ideology of individual and group power and prestige, and the creation of a vast cultural landscape within which the monument complexes were central to a ritual cycle encompassing a substantial geographical area.

[290] Picturing New Socioeconomic Realities for Coast Salish Societies of the Mid-Holocene Based on Excavations of a Katzie Village

Recent excavations at the archaeological site DhRp-52, a large village located in the core of contemporary Katzie First Nation territory, yields significant insights into mid-Holocene resource management and regional socioeconomies amongst Coast Salish communities of the Northwest Coast. The site contains permanent residences, a substantial wetland garden, and evidence of large-scale trade networks. These finds stretch both the temporal and spatial scope of extant ethnographies. This paper uses a series of illustrations to both visualize and contemplate the gender, ritual, social, political, and economic implications of the DhRp-52 evidence for current understandings of mid-Holocene lifeways amongst the Coast Salish.

[321] The D-Shaped Kiva at Point of Pines Pueblo, Arizona

Emil Haury’s 1958 synthesis of the Pueblo III-Pueblo IV period (A.D. 1265-1450) archaeology of Point of Pines Pueblo in east-central Arizona, is the US Southwest’s classic case study in how to reliably infer ancient migrations. Field school excavations conducted between 1946 and 1960 at Point of Pines by the University of Arizona Department (now School) of Anthropology and the Arizona State Museum uncovered compelling evidence of immigrants from the Kayenta region of far northeastern Arizona and southeastern Utah. One of the key markers of this group of foreigners is a D-shaped kiva. Because the excavations at Point of Pines Pueblo have never been fully reported, this ancient ritual structure is not as well understood as it should be. A recent study of materials in the Point of Pines archives and a reanalysis of the ceramic assemblage recovered from the kiva have shed new light on the immigrant occupation.

[252] Plaza and Courtyard Investigations at Xunantunich, Belize

Xunantunich is best known for its Late to Terminal Classic occupation. The Mopan Valley Preclassic Project began investigating the site in 2008 to gain a better understanding of the site’s Preclassic and Early Classic components. Our research design includes intensive plaza investigations to uncover buried architecture and features. We have concentrated our efforts in two areas of Xunantunich, Group D and Group E. Group D is an elite residential group with an eastern pyramidal ancestor shrine. A previously unidentified small rectangular platform suggesting association with the ancestor shrine was exposed beneath the Late Classic courtyard. This buried architectural feature was unusual and associated with a large number of smashed Preclassic and Protoclassic ceramics. These ritual deposits may represent activities related to ancestor veneration. Group E is a Preclassic site core with an E-group architectural arrangement. Excavations in the plaza at Group E have revealed several important architectural features as well as a possible Preceramic occupation layer. In this paper, we highlight some of our recent finds buried beneath plazas and courtyards and how this research has updated our understanding of the development of the Xunantunich polity.

[51] Analysis of the Economic Structure of the Zhouyuan Site in the Shang and Western Zhou Periods
This paper discussed the economic structure of THE Zhouyuan Site in the Shang and Western Zhou Periods. Through the analysis of agriculture tools in different periods and at different sites, this paper suggests the economic structure might have changed significantly from the Proto-Zhou period to Western Zhou period. The percentage of agriculture tools declined obviously in the Western Zhou period, and at the same time, a large number of handicraft workshops appeared. Meanwhile, the percentage of agriculture tools in the Western Zhou period is also much lower than that from other sites in the same period, such an Tianma-Qucun site, which indicates that the people living in Zhouyuan site might have other sources of food supply. Nevertheless, the data that could be analyzed is quite limited, so it’s still a preliminary conclusion.

[108] Sorotomo (AD 1200-1500): Excavations at a Malian Center of Power
Sorotomo, at 72ha, is one of Mali’s largest known settlement mounds. More importantly, unlike most other Malian urban tell complexes, its historical associations are emphatically political and military - not commercial. This makes it an important exception to the rule that West African cities were primarily heterarchical trade entrepots. Historical sources on Sorotomo are scarce – but tantalising. In the Tarikh es-Soudan, it is recorded that in the Empire of Mali’s principality of Jenné, an area between the Niger and Bani rivers, there was the ‘sultanate of Zorra.’ Likewise, the German anthropologist Leo Frobenius collected oral traditions early in the 20th century which named ‘Soro’ as a major center of political authority for the Empire of Mali. We (re-)located Sorotomo (“the ruins of Soro”) in 2005 during a broader oral historical and archaeological survey of the Segou region. In 2006/2007 and 2009/2010 we undertook excavations, including a large exposure. The results of this fieldwork, C14 dates and subsequent analyses of artifacts, fauna and flora are summarised in this paper.

[316] Late Holocene Resource Depression in San Francisco Bay: New Mammalian Indices from the Yerba Buena Shellmound
Resource depression has become a key issue in human foraging ecology in archaeology. As high-ranked prey decrease in abundance due to predator (in this case human) activity, people begin to exploit smaller, lower-ranked prey. This transition can be measured using abundance indices, with relative values decreasing over time. In this study, artiodactyl abundance indices were created for the terrestrial faunal material at the Yerba Buena Shellmound site, located on the tip of the San Francisco Bay Peninsula. Relative abundances of artiodactyls and large mammals (due to the relatively high amount of long bone shaft fragments) in relation to lagomorphs and rodents were measured over time. This poster presents the results of zooarchaeological analysis at the site. While it was expected that the relative abundance of artiodactyls and large mammals would decrease over time if resource depression was occurring, the indices instead exhibited an increase over time. There are likely a number of factors influencing these results, including NISP inflation due to increased fragmentation or a shift in foraging patch use. Exploration of ethnographic literature can elucidate these factors and identify others contributing to these results.

Macdonald, Danielle (Centre national de la recherche scientifique)
[335] Micro-topographies and Human Action: Interpreting Behaviour through Surface Traces
Surfaces act as a barrier between objects and it is these surfaces which ultimately interact when two objects come into contact. Traces of these interactions are often left on surfaces, allowing us to interpret past actions. Lithic use-wear analysis is based on the concept that different materials and motions will produce distinct traces on the surfaces of stone tools. Recent developments in the field have applied
microscopy techniques developed for the field of surface metrology to lithic assemblages, creating microscopic three-dimensional ‘landscapes’ of tool surfaces. This presentation focuses on how we make interpretations from these traces and the epistemological challenges faced when asking questions related to human behaviour from microscopic data.

MacEachern, Scott (Bowdoin College)  
[198] (Un)becoming States: Their Neighbors and the Wandala South of Lake Chad
Expansionistic states like Wandala came to occupy the plains around the northern Mandara Mountains of Cameroon and Nigeria in the middle of the second millennium AD. This is conventionally seen as generating a set of core-periphery relations with ‘marginal’ societies, especially diverse and decentralized Mandara montagnard communities. Archaeological and other data indicate that this image of sociopolitical relations is incorrect: ‘state’ and ‘marginal’ identities interpenetrated and mutually constituted each other in the area. Mandara societies did not exist ‘against’ the state as much as beside, within and around it. Such perspectives may also be useful in understanding modern frontier phenomena in the area.

MacFarland, Kathryn (School of Anthropology, University of Arizona)  
[92] The Tngri’s Home: A Deer Stone
The Scythian, Saka, and Xiongnu religious landscape is differentially expressed across Central Eurasia, throughout the Iron Age (ca. 1,000-100 BCE). This is demonstrated archaeologically by the concentration of architectural features (i.e., kurgans, khirigsuurs, deer stones) and ritualized locations throughout Central Eurasia. Additionally, artifacts and iconography depicted on variably anthropomorphized Deer Stones are predictive of burial assemblages found within kurgan burials throughout Central Eurasia. The closest analog to this religious belief system is Tngriism, a belief system documented by the Secret History of the Mongols (ca. 1227 CE) and in ethnographic accounts of Mongolian prayers documented by Western travelers (Heissig 1970). Tngriism is associated with the pantheon of 99 gods or heavenly beings (Tngri) which are geographically grouped; each grouping is variously worshipped by prayers and sacrifices. Deer stones mark significant locations within the Iron Age Central Eurasian religious landscape. This paper proposes that deer stone sites mark particular spots in which rituals and prayers were devoted to a particular Tngri; deer stone locations are potential “homes” for Tngri. It is also possible that deer stones themselves are physical representations of iconography and other aspects of material culture, such as tattoos, for the Tngri associated with a location and/or region.

[60] Shrines on High Places: An Analysis of Settlements on Hilltops in North Central Mexico During the Epiclassic (600-900 A.D.)
For a long time, settlements on hilltops in the north central region of Mexico have been interpreted as a defensive response to risk and confrontation between village societies that inhabited the northern frontier of Mesoamerica. Although such confrontation is evident in some cases, these generalizations about the archaeological record have obscured our understanding of other meanings related to the construction of structures in prominent points in the landscape. This paper aims to make contributions to the discussion on the symbolic and ceremonial nature of some settlements located on the north side of the El Río Verde-San Pedro and Los Altos de Jalisco. Through an analysis of the landscape where these sites are located, as well as other key indicators such as rock art, caves, petroglyphs and altars, we propose two ideas: in the first place, the location of sites on hilltops is not a regional settlement pattern trend, and consequently a situation of confrontation and conflict is doubtful; and second, some of these sites, instead of serving as defensive locations, could have been shrines related to the cult of caves and mountains.

[84] An Experimental Approach to Antler Working at Körtik Tepe (SE Turkey) during Pre-Pottery Neolithic A (PPNA)
The recent archaeological projects in southeastern Anatolia (Turkey) have shed new light on the revolutionary socioeconomic transformation of human lifeways during the Terminal Pleistocene and Early
Holocene. Körtik Tepe is an important Pre-Pottery Neolithic A (PPNA; 10th millennium BP) site excavated in the region due to its fascinating mortuary practices that contain rich and diverse grave goods and sophisticated symbolism as well as round architectural structures. This paper presents an experimental work on antler technology to add new data to ongoing zooarchaeological and archaeological research at Körtik Tepe. The experiments specifically probe blank production, antler reduction sequencing, and manufacturing strategies to gain insight into antler working. First, we replicated antler tools to test the validity of our previous morphological and functional categories for the Körtik Tepe antler assemblage. Second, we documented and investigated various manufacturing techniques more closely. Lastly, we contextualize antler work and technology during a period of rapid social, ideological, and economic change at the end of the Pleistocene.

Mack, Stephanie (University of New Mexico)

Sizing Up: Chert Cobble Bed Sourcing within the Petrified Forest National Park

Petrified Forest National Park is rich in raw material sources: in addition to petrified wood, beds of secondary chert cobbles from the Triassic period (250-200 myr) are an abundant lithic raw material source. Although petrified wood is by far the most exploited lithic raw material in the park’s history of human occupation, it is not the best material for flake stone production because while it yields and retains a sharp edge, it still fractures along imperfections caused by crystallization of the original tree ring structure. The cryptocrystalline fracture properties of local chert however are more conducive to lithic reduction (Wandler 2011 et al.). This poster analyzes the availability and average size of chert cobbles within the park in order to identify why chert appears less often than petrified wood in archaeological assemblages throughout the history of occupation of Petrified Forest National Park.

Osteological Landmark Quantification and the Taphonomy of the Late Neolithic Rock-Cut Tomb of Bolores, Portugal

Five seasons of excavation at Bolores, a Late Neolithic (2800-2600 cal B.C.) collective burial in a rock-cut tomb in the Portuguese Estremadura, yielded thousands of human bone fragments. Because few articulated segments were recovered from the commingled remains at the site, standard human osteological data collection protocols developed primarily for recording complete individuals found in discrete contexts were found to be difficult to apply. Zooarchaeological methods for recording disordered and fragmentary animal remains yielded more precise information on the site’s population and taphonomy. Our methodology, which builds upon the previous work of Christopher Knüsel and Alan Outram, has helped to refine the MNI (minimum number of individuals) and has helped to define use areas within this ritual space.

Mackay, Alexander (University of Wollongong)

The Iceberg’s Fundament: The Role of Bipolar Technology in the Later Pleistocene Archaeology of the Western Cape, South Africa

Descriptions of technological change in late Pleistocene southern Africa have often focused on the outstanding elements of technological systems – those which allow the development of contrasts between periods. To an extent this has led through-time similarities in some technological components to be overlooked. Bipolar reduction is one element of technology that persists through the late Pleistocene, fluctuating in frequency but rarely if ever absent. Using data from several sites in the Western Cape of South Africa this paper documents the role of bipolar as a critical strategy facilitating changes in material selection and flake production that likely underwrote adaptation to diverse sets of conditions from >75 ka through to the Holocene.

Mackenzie, Simon (University of Wyoming)

Determining the Age and Sex of Rock Art Hand Spray Artists, Johnson County, Wyoming

The opportunity to determine information about the artists behind rock art rarely occurs, however hand
sprays make this possible. A series of sites within Johnson County, Wyoming contain an unusual amount of hand sprays which were analyzed to learn more about the creators of prehistoric rock art in Wyoming. Rock art panels were recorded through use of stereo photography from which three-dimensional computer models were produced. A comparative collection of hand sprays from individuals of known age and sex were collected and digitally measured. This collection was used to determine a set of measurements which best represented relative and morphologically changes with are related to age and sex. The measurements from the comparative collection were applied to the rock art hand sprays in order to determine the age and sex of individuals who created the site. This study shows the potential of using three-dimensional computer modeling for rock art research and offers a large database of known hand sprays which could be utilized for future research.

MacKie, Quentin (University of Victoria)
[282] The Middle of Somewhere: Periphery as Centre on the Northwest Coast of North America Southern Haida Gwaii lies on the westernmost margin of the North American continental shelf. To the east, it is over 100 kilometers of open water to the British Columbia mainland, while to the west the abyssal depths of the NE Pacific are only a few kilometers offshore. Nonetheless, over 100 terminal Pleistocene or earliest Holocene sites are recorded from its shores, one of the densest known concentrations on the Pacific Coast. These include the 10,700 year old Kligii Gwaay wet site, which shows a logistically-organized and fluently maritime economy. Its location on a small island near the southern end of Haida Gwaii encourages us to characterize it as “remote”, perhaps because it is far from a viable terrestrial homeland. In this paper I explore how archaeologists and anthropologists have described and characterized the apparent remoteness of Haida Gwaii. I then offer a commentary based around place, environmental shape, maritime landscape theory, and locational centrality within complex coastlines.

MacLellan, Jessica (University of Arizona), Takeshi Inomata (University of Arizona) and Daniela Triadan (University of Arizona)
[61] The Foundation of a Very Early Maya Ceremonial Center: Investigations at Ceibal, Guatemala, Since the Harvard Seibal Project
The lowland Maya center of Ceibal was first investigated in the 1960s, by the Harvard Seibal Project, which showed that Ceibal was founded surprisingly early, by 900 B.C. Building on Harvard’s work, the Ceibal-Petexbatún Archaeological Project has conducted further excavations at Ceibal, focusing on the site’s earliest components. Takeshi Inomata and colleagues discovered that a formal public plaza was constructed at the site’s foundation, around 1000 BC, and that Ceibal’s founders were influenced by non-Maya settlements to the west, in Chiapas. The E-group complex at Ceibal is one of the earliest known in Mesoamerica. Early domestic areas have also been uncovered. In addition, Inomata has refined Jeremy Sabloff’s original ceramic chronology using new carbon dates. Ceibal’s initial ceremonial space and public rituals – including Olmec-style greenstone axe caches – set it apart from the majority of early Maya sites, such as Cuello, which began with small domestic structures and developed public spaces over time. New data from Ceibal have dramatically changed our understanding of interregional interactions within Mesoamerica during the Middle Preclassic period.

[335] Changes in Scale and Survey in the Maya Subarea
The scale of archaeological survey has significantly changed over the past few decades. It is imperative to understand how these changes of scale and methodology have influenced research. The primary motivation for changes is the development of new technologies and techniques. Surveyors in the Maya subarea have often been at the forefront of these changes. This paper addresses the historical development of survey in Belize, identifying important developments and consequent changes in the research questions. To address recent advances, the ancient Maya center of Waybil located within dense tropical forest of western Belize provides an excellent case study. Over several years Waybil has been subjected to a variety of different survey methods, progressively increasing the scale of analysis. Survey methods utilized at Waybil include tape and compass, theodolite, total station, and recently LiDAR imagery. Examining how survey progressed at Waybil provides insight into how different methodologies facilitated different research questions and ultimately influenced the interpretation of both settlement and agricultural strategies. Archaeologists today have access to powerful survey techniques
increasing the scale of analysis. This makes it ever more important to understand how changes in scale affect not only what questions are asked but also what interpretations are made.

[29]  The Farms of Hunters in Norse Greenland

The settlements of the Greenland Norse lasted from c.980-1450 A.D., throughout their existence constituting the ultimate geographical and environmental frontier of Northern Europe. Through the Vatnahverfi-Project, research on settlement and dietary patterns of the Norse has shown how they were quick to adapt to local conditions and resource availability, resulting in settlement and economic patterns quite distinct from elsewhere in the North Atlantic. Our research suggests that these transformations were partly driven by climatic deterioration, but primarily as these exacerbated other already existing societal structures: low population densities and increased isolation from the European networks on which the Norse depended could have left them increasingly vulnerable to change in spite of their apparent economic adaptability.

In our new ongoing research project Diet, Health, and Social Status in Norse Greenland - Human Securities in a Changing World we investigate new and detailed combined evidence of dietary, organizational, and economic developments in the Norse settlements to explore what 'here and now' solutions were available to the Norse, the responsive range of their cultural toolbox and societal setup to change, or even transformation, and how human strategies and solutions impact the individuals and society, in one way or the other.

[193]  Cultural Transmission of Structured Knowledge and Technological Complexity: Axelrod's Model Extended

Cultural transmission models are coming to the fore in explaining increases in the Paleolithic toolkit richness and diversity. Analyses suggest that diversity increased due to relaxation of conformism, due to the effects of demographic expansion on cultural diversity, and the effects of extinction and recolonization in metapopulations. During the Paleolithic, however, technologies increase not only in terms of diversity but also in their complexity and interdependence. As Mesoudi and O'Brien (2008) have shown selection broadly favors social learning that is hierarchical and structured, rather than information which is piecemeal and independent. The addition of structured information acquisition potentially explains how the complexity of technology changes along with diversity. Here, we introduce a variant of Axelrod's model of cultural differentiation, modified such that homophily and conformism refers to the content or "semantics" of traits, instead of simply their frequencies. We examine the conditions under which structured suites of traits develop and differentiate in the model, which can represent the chains of prerequisites, "background" information, and local specializations characteristic of real technology traditions. Our results point to ways in which we can build more comprehensive explanations of the archaeological record of the Paleolithic as well as other cases of technological change.

Magargal, Kate

[207]  Fetching Firewood: Exploring the Relationship between Site Locations and Fuel Sources Access to environmental resources is an important factor in determining prehistoric settlement decisions. The location of wood resources, for example, was important to societies with wood-based architecture. Access to woody fuels should also be a constraint for populations subsisting on cooked foods. A more detailed understanding of the distribution of temporary camps and habitation sites relating to the probable distribution of plant communities drawn from historic maps may provide important insight into site location factors relative to fuel sources. This study examines archaeological site distributions as a
function of historic vegetation. The results provide insights into the ecological constraints individuals face within variable environmental landscapes.

Magdalena, Matczak (University of Poznan)  
In my paper I present a view on emotions from a social bioarchaeological perspective. I present skeletons with markers associated with diseases from the sites of the early medieval (10th–13th century) Kaldus in Poland. The research questions are: 1) How to find emotions which are hidden in the skeletons? Such emotions might include: fear of the ill, empathy and compassion for them, sadness and sorrow after the bereavement, aggression toward outcasts, hope for healing, respect for the deceased, anxiety etc. 2) How to investigate social relationships between the ill and the healthy? Understanding the emotions of the healthy towards the ill might help clarify the social status of the ill in past communities. In terms of archaeological research, cultural analysis of the so-called anti-vampire or atypical graves might examine the relationship between illness and emotions. Specifically, the setting of the body in the grave might show hidden or explicit emotions of the living toward the dead.

[292] Dietary Implications of Exchange from Kichpanha, Belize  
This paper reports the results of analysis of skeletal and dental pathological conditions and stable carbon isotope ratios derived from collagen and tooth enamel from Kichpanha, Belize. The site was occupied from the Middle Preclassic through the early Postclassic, but the greatest number of skeletons are associated with the Late Preclassic and Late Classic. Maize was an obvious part of the diet throughout the occupation, but protein sources are derived from meat and aquatic sources. Exchange or trade must have occurred for residents of Kichpanha to acquire the aquatic protein sources.

[306] A Bioarchaeological Analysis of Late Prehistoric Health and Diet at the Hatch (44PG51) and Claremont (44SY5) Sites  
The Coastal Plain of Virginia provides a highly dynamic environmental context that contains a diverse array of potential dietary resources. This study provides a bioarchaeological assessment of overall health and diet for two sites located on the south side of the James River: the Hatch (44PG51) and Claremont (44SY5) sites. The assemblages provide a unique opportunity for comparative study, representing different portions of the Late Woodland period with marked differences in mortuary patterning. The Hatch site (MNI = 36) dates to the first half of the Late Woodland period (A.D. 900 to 1250) and the burials were mostly single, primary interments. Claremont Ossuary 1, a secondary burial deposit (MNI = 14), likely dates to the second half of the Late Woodland period (A.D. 1250 to 1607). Both sites had ready access to a variety of marine, riverine, and terrestrial foods, and span the period when maize is assumed to have become a dietary staple throughout Virginia. This study focuses upon the analysis of carious lesions, linear enamel hypoplasias, cribra orbitalia, and porotic hyperostosis to develop a more refined understanding of the potential introduction and impacts of maize agriculture within the Middle Atlantic region.

[236] Occupying Wide Open Spaces? Late Pleistocene Hunter-Gatherer Activities in the Eastern
Levant
With a specific focus on eastern Jordan, the Epipalaeolithic Foragers in Azraq Project explores changing hunter-gatherer strategies, behaviors and adaptations to this vast area throughout the Late Pleistocene. In particular, we examine how lifeways here (may have) differed from those in surrounding areas and what circumstances drew human and animal populations to the region. Integrating multiple material cultural and environmental datasets, we explore some of the strategies of these eastern Jordanian groups that resulted in changes in settlement, subsistence and interaction and, in some areas, the occupation of substantial aggregation sites. Four years of excavation at the aggregation site of Kharaneh IV suggest some very intriguing technological and social on-site activities, as well as adaptations to a dynamic landscape unlike that of today. Here we discuss particular aspects of the Kharaneh IV material record within the context of ongoing palaeoenvironmental reconstructions and place these findings in the wider spatial and temporal narratives of the Azraq Basin.

Post-Emancipation Community Building at Charles’ Corner in Tidewater Virginia From 1862-1922
In 1918, nearly 11,000 acres of land on Virginia’s lower peninsula were commandeered in order to create the Yorktown Mine Depot, now known as the Yorktown Naval Weapons Station (NWSY). Charles’ Corner was one of three neighborhoods on property appropriated by the U.S. Navy and had been a majority African American settlement established during the Peninsula Campaign of the Civil War. Superstructures were razed soon after residents left; however, the homesteads were left relatively undisturbed for the last ninety years. As a result, the archaeological sites encapsulate a critical period of African American history during the socially and economically difficult transition following Emancipation. Phase II archaeological assessments conducted in 2008 focused on four sites representing thirteen different households at Charles’ Corner. Recovered artifacts and recorded features, including brick-lined wells and a modified spring, serve as a testament to the African American families who were able to build a community and become economically self-sufficient in the Jim Crow South.

The Business of CRM: Achieving Sustainability and Sustaining Professionalism
The development of cultural resource management (CRM) as a profession.industry intensified in the United States after key federal legislation was passed in 1974. After several decades, practitioners realized that already established professional organizations, with more scholarly roots, could not fully serve the complex needs of a “profession” that was intimately tied to both heritage advocacy and business. The American Cultural Resources Association (ACRA) was formed in 1995, and today, with over 150 firms as members, is a hybrid between a professional organization and a trade association. ACRA’s goal is to be the voice of the billion dollar CRM industry. The association’s efforts to provide members with the tools to professionalize and sustain the industry are exemplified by the services it provides: e.g., building a solid image for the industry; supporting and promoting CRM at the national level by “educating” legislators about preservation and the industry; disseminating information via conferences, networking opportunities, workshops, newsletters and updates, printed materials, and the Internet and the World Wide Web; establishing and maintaining relationships with organizations having common or overlapping purposes; collecting metrics on the industry and its practitioners; and establishing and encouraging best practices.

Networks of Ceramic Production and Exchange in the Late Horizon: Characterization of Ceramic Styles and Clays on the Central Coast of Peru
Our goal is to reconstruct networks of ceramic production and exchange during the Late Horizon through LA-TOF-ICP-MS, INAA, and petrographic characterization of ceramic styles and clay sources from the central coast of Peru. The Inca empire created the conditions of a mini world system. The products and networks of exchange connected heterogeneous populations, and thus the identities of producers,
traders, and builders of public and domestic spaces did not coincide. Imperial ideology materialized in official architecture and paraphernalia, but not always in vernacular versions. Its producers followed local and regional styles and technologies. We believe the pottery styles preceding the Inca conquest were not that affected by the new scenario. Besides, the empire’s political complexity was reflected in a variety of styles, due to the co-existence of local traditions, with production that imitated foreign styles, and the forced displacement of potters. Our research identifies such scenario on the central coast. Focusing on technological traditions, which are more resistant to change, we evaluate hypotheses about multi-ethnic communities and multi-stylistic ceramic production by contrasting compositional groups with clay sources and pottery pastes, wares, and styles previously defined by macroscopic methods.

Malainey, Mary (Brandon University), James Skibo (Illinois State University) and Timothy Figol (Brandon University)  

The analysis of archaeological pottery has long been recognized as a valuable endeavor because the combination of functional and stylistic attributes provides a wealth of information about the vessel and its maker. Intra- and inter-site comparisons are essential; however, grayscale images of pot fragments may not convey the salient features of vessels. Access to institutional pottery collections can be difficult, expensive and time-consuming. We are addressing these issues by performing morphological, use-alteration and stylistic analyses of individual vessels and creating precise three-dimensional vessel models using computer-assisted design (CAD) software. "Whole vessel" morphological analysis is then performed on the models using the CAD program. We are developing a web-based, interactive searchable pottery database to share our results with others. Each record will include high resolution digital images and detailed descriptions of vessel morphology, decoration and evidence of function obtained through residue analysis and use-wear analysis. Relevant published sources about the site and pottery typology will be included. Our training materials showing how to conduct the detailed analyses and generate accurate CAD models of whole or partially reconstructed vessels using software that is free-of-charge to students and educators are available to interested researchers.

Maldonado, Ronald (Navajo Nation Historic Preservation Dept)  
[18] The Navajo-Gallup Water Supply Project as seen from the Navajo Nation Historic Preservation Department

The Bureau of Reclamation’s Navajo-Gallup Water Supply Project (NGWSP) will bring domestic water to the eastern portion of the Navajo Nation as part of the New Mexico Water Settlement. Construction of the pipeline will directly impact hundreds of ancient and modern cultural resources within the San Juan Basin, a landscape that figures prominently in Navajo clan origin and ceremonial histories. Unlike many previous archaeological projects that have examined a relatively small area, construction of NGWSP will cross the western, southern, and eastern portions of the San Juan Basin. This will allow for a broader examination of the cultural resources across the entire basin. The success of the project in avoiding damage to sites important to Navajo traditions will rely on planning through consultation with the Historic Preservation Department. Perhaps the greater value of the project to the Navajo Nation is that it will provide the Historic Preservation Department with the means to develop a digital database for cultural resource information. In this way, the project will have a long term effect that will benefit the whole reservation.

[211] Pre-Columbian Mining in the Atacama Region of Northern Chile: Present Knowledge and Future Research

The second-highest mountain range in the world, the Andes are particularly rich in mineral resources and have given origin to a long tradition of mining and metallurgy, which has led to one of the most important metal industries in the world. While a variety of minerals for gold, silver, and tin occur in the region, copper was and has continued to be the most important metal produced in the south central Andes to this day. Richest veins of copper ore are found throughout the Atacama Desert, where they are broadly distributed as a product of ancient hydrothermal actions. Pre-Columbian populations made various uses of these and a wealth of other minerals, as early as the second millennium BC. The evidence for ancient
mining in the Atacama region of northern Chile is reviewed, and directions for future research in the area are discussed.

Malischke, Lisa Marie (University of Alabama, Tuscaloosa) [221] The Short-Lived Site of Fort St. Pierre (1719-1729) in Comparison to Other Early Colonial Louisiana Locales throughout the Mississippi River Corridor.

Fort St. Pierre (1719-1729), located near present-day Vicksburg, Mississippi, was a short-lived and lightly manned frontier fort. Absent were an accompanying French settlement and mission. The site was excavated in the mid-1970s, and the whole assemblage was recently re-evaluated using correspondence analysis. Though correspondence analysis is an interesting tool for examining and comparing whole assemblages, it is best used as a starting point for the discussion of the uniqueness of each site, the forms of adaptation and adjustment adopted by the inhabitants, and how material culture both shaped their lives and was shaped by their individual stories. Several defining artifact classes characterize the site of Fort St. Pierre in comparison to the assemblages from other early Mississippi River corridor locales such as: French forts with civilian settlements, private French plantations, French entrepôts, and contemporaneous Native village sites. Each of these site types have artifact classes that characterize their overall artifact assemblages. Correspondence analysis compares similarities and differences among all of the sites while simultaneously comparing the artifact classes. The results of this process were confirmed by both cluster analysis and seriation analysis, and will be discussed in this presentation.

Malloy, Maureen (Society for American Arch) [96] Archaeology Education in the U.S.: Past, Present, and Future

Archaeology education has been a part of archaeological practice in the U.S. for the past 30 years and is firmly rooted in the discipline's widely shared belief that public education about archaeology is key to protecting and preserving sites. But to be truly effective, archaeology education efforts must look beyond our own discipline’s needs and focus on meeting the needs of educators and other publics. It must be situated in, informed by, and evolve with theory and practice in the emerging subdiscipline of public archaeology. As a shared endeavor designed to meet common goals, archaeology education today can both inform and help solve contemporary problems beyond the looting and destruction of archaeological sites. This paper provides an overview of the history of archaeology education as it has been practiced in the U.S. since the 1980's. The development of the award-winning curriculum guide “Project Archaeology: Investigating Shelter,” serves as a model of best practice in creating formal archaeology education materials today.

Malloy, Kevin (University of Wyoming) and Derek Hall [201] Conspicuous Consumption as Conservation?: The Effects of Climatic and Environmental Change on Park Landscape Design in Medieval Scotland, AD 1100–1600

Unlike their English counterparts, research into the emergence, function, and symbolism of medieval parks in Scotland has been woefully neglected. Parks emerge in the late twelfth century during the height of the Medieval Climate Anomaly, remain popular through the Little Ice Age, and continue to be used in some form up to the present day. Until recently, descriptions of these sites tended to present parks as one-dimensional, expensive, aristocratic deer hunting arenas, rarely taking into account the wider environmental, climatic, and social context of the period, or any additional site functions. Through a series of archaeological excavations, archival research, and environmental examinations, this on-going study attempts to demonstrate that parks were complex in design by exploring the link between their emergence and functions and the environmental and climatic conditions of the medieval period. This study has found evidence that changing climate and environment played a role in the social issues that led to deforestation and timber depletion, leading some parks to become an avenue for conspicuous consumption through the limiting of resource access, while simultaneously becoming a means of woodland conservation.

Maloney, Tim (Australian National University, School of Archaeology and Natural History) [217] Detecting Changing Technological Investment in Bifacial Point Technologies from Northern
Australia
Analyses of Australian stone tool assemblages frequently depict a two phase industrial sequence, where major change in technological investment is represented only by the appearance of new artefact morphologies in the Holocene, such as bifacial points. Archaeologists working in the Kimberley region of northern Australia have focused lithic artefact studies on the production of pressure flaked points or Kimberley Points. The manufacturing process of Kimberley Points, involving a staged sequence of preform production and different methods of pressure flaking to the margins, was observed ethnographically. Reduction sequences and morphological variability of these aesthetically amazing bifacial points have seldom been contrasted with the morphological range of direct percussion point and retouched flake technologies. Temporal and technological associations between Kimberley Points and direct percussion points are poorly understood. New data from surface and excavated assemblages offers a robust explanation of bifacial point variability within a framework of technological organisation and reduction thesis data. New radiocarbon dates suggest a major shift in technological investment, from an emphasis on maintainable and flexible direct percussion points from around 5000 BP, to a later development of a specialised, staged, and teleological production process of Kimberley Point manufacture beginning around 1000 years ago.

[288] Long-Term Social Stability in Precolombian Costa Rica
Costa Rican archaeology has long been characterized by very prolonged cultural phases with relatively subtle changes in the ceramic complexes which represent each phase. There have been two general explanations for this; first, that there still has been too little research with too few radiometric dates to be able to divide these phases further, and, second, that these long phases are actually representative of the Pre-Colombian societies. Gradual changes in some ceramic types as well as temporal differences in the appearance of these changes between types point to relatively stable societies that existed over the course of 3000 years of permanent settlement. However, as evidenced by changes in architectural practices and the increase in the presence of sumptuary goods, these societies gradually grew more complex, evolving from egalitarian horticulturalists into complex chiefdoms that most probably boasted the existence of a warrior class. Nevertheless, even these seemingly major changes were very gradual. This paper will present data from recent excavations as well as bibliographical research that supports this model and demonstrates social stability in Pre-Columbian Costa Rica.

Malpass, Michael (Ithaca College)
[38] Sonay: A Reassessment of Its Age and Implications for Coastal Wari Sites
Sonay is considered to be a small Wari center in southern Peru. It consists of an orthogonal compound with very few artifacts. It was dated to the late Middle Horizon by two calibrated dates in the tenth century and architectural similarities to other Wari sites. However, the late dates and absence of good Wari ceramics are an issue. Colleagues have suggested the site represents an attempt by a later local lord to copy Wari material culture in order to improve her or his status. This paper will review the evidence for Wari affiliation and consider the alternative hypothesis. The broader issue to be addressed is how much and what kind of data are needed to establish cultural affiliations. Are some data types given preference over others? Other late coastal or near coastal sites will be discussed for comparison.

Manahan, T. Kam [305] see Munro-Stasiuk, Mandy

Mandel, Rolfe (Kansas Geological Survey)
A strong case is made in this paper that the most important factor contributing to the rapid development of geoarchaeology over the past 35 years has been the growth of federally mandated cultural resource management (CRM), and that the Great Plains has been at the epicenter of this development. More than 95% of the archaeological investigations conducted in the Plains since the late 1960s have been tied to CRM projects. During the first decade of CRM, geoscientists were often limited to describing soil profiles at sites and/or providing terrain analysis for survey areas. However, by the 1980s geoarchaeology moved beyond the descriptive stage: geoscientists were providing archaeologists with insights about the nature of the archaeological record. Today, earth-science specialists involved with CRM often are called upon to
map landform sediment assemblages and determine the potential for buried cultural resources. At individual sites, they are usually expected to interpret depositional environments and site-formation processes, and to reconstruct paleoenvironments. Hence, as the needs of CRM evolved, geoarchaeology evolved from something done by a specialist at an old and/or deeply buried site to a cooperative effort among archaeologists and earth-science specialists in a wide variety of archaeological contexts.

[262] The Alluvial Geochronology of Pharo Village and Implications for Cycles of Site Occupation and Abandonment

The results of geoarchaeological investigations at Pharo Village, a Fremont hamlet situated on a large alluvial fan in central Utah, are discussed in order to reveal ways in which changes in alluvial dynamics contributed to the rise of Fremont farming there as well as the site’s eventual abandonment. Cutbanks along Pharo Creek, the meandering stream adjacent to Pharo Village, were mapped and sampled during fieldwork in 2013. Field and subsequent laboratory analysis allowed reconstruction of the alluvial geochronology at the site. Carbon samples from mapped sections and buried paleosols were radiocarbon dated and correlated to additional dates generated from the site’s archaeological collection housed at the Natural History Museum of Utah. Buried soils examined in mapped sections indicate a period of stability on the landform where Pharo Village is located, and could explain when and why the Fremont utilized this location. The relationship of high energy flood deposits above the buried soil contributes to discussion of site abandonment. From these data, interpretations are made concerning the contributions of local alluvial shifts to the overall termination of Pharo Village occupations and by association, the larger Fremont Complex around 600 BP.

Manion, Jessica (University of Calgary)

[153] Memory and Manipulation in the Greater Nicoya

Ceramic vessels from the Greater Nicoya region of Central America are characterised by great variation occurring throughout several periods. The form and decoration of these vessels are related to their cultural associations, and the examination of the materialization of social memory presented in these vessels helps to elucidate the political landscape presented by different factions and agents. Migrations into the area are cited as the impetus behind changes in iconography and other vessel characteristics between time periods, and these cultural differences are visible through changing aspects of memorialisation, and even erasure, as evident in the material record. Analysis of a collection of vessels from the region reveals how the social memory was presented and manipulated over time, and can give clues as to the identities of the people controlling the formation of social memory within the Greater Nicoya region.

[244] Barrow Island Arid Coastal Economies of the Pleistocene and Early Holocene

Barrow Island archaeofaunas provide unique insight into understanding long-term arid coastal economies of Australia’s northwestern coast. The island’s limestone geology, coupled with its large well-protected caverns, is highly unusual in northern Australia, which is dominated by acidic sandstones creating poor preservational environments for bone. The exceptional preservation of skeletal material at Barrow is evidenced by the recovery of delicate bird tracheal rings and fish cranial elements. The Barrow Island Archaeology Project thus provides an exciting opportunity to explore a range of questions regarding human behavior, including responses to eventual island adaptation. Preliminary findings from the 2013 excavation season indicate that early Holocene economies consisted of mixed marine-terrestrial faunas, while the Pleistocene assemblage was markedly more terrestrial in nature, as the area became part of the coastal hinterland ranges. However, despite significant environmental shifts and increased distance to the coastline during the Pleistocene, people continued to utilize marine resources both as dietary and utilitarian items.

Mannheim, Bruce (University of Michigan) and Alison R. Davis (Isaacson, Miller)

Our goal is to interpret the practice of cranial modification in terms of what we know archaeologically, historically, and ethnographically about the relationships between developing personhood, place, language and social differentiation (some which have endured until now). We will track this practice in the south central Andes along a diachronic axis from the Formative period until the time of the European invasion, tracing changes in a child care practice that became an index in an ideological complex that connected personhood to place and language within an "organization of diversity".

During the Formative period in Cusco, a single ubiquitous child care practice produced a variety of non-standardized head shapes that can neither be categorized by form nor used by archaeologists as proxies for cultural or linguistic difference. In contrast, in Inka and early colonial contexts, varied techniques crafted standardized and distinct head shapes that provide one of the few forms of material evidence for the ways in which cultural and linguistic differentiation played out in everyday settings. Our goal, then, is to understand cranial modification as the outcome of social processes differentiated by locality, gender, and age rather than simply as a classificatory device.

Manning, Katie (UCL, Institute of Archaeology)
[187] Cycles of Change in Neolithic Animal Exploitation Strategies
The domestication of plants and animals facilitated major changes in human ecology, demography, and social organization. Despite the seeming advantages of domestication, however, it is clear the process was not a linear one. This paper explores the stability of early domestic economies in Neolithic Europe from the perspective of animal resource exploitation. We focus on a number of regional case studies, using over 400,000 animal remains to assess changing cycles in domestic vs wild animal resource exploitation. We present our results in relation to regional climatic events and explore potential links between animal exploitation strategies on the one hand, and human population dynamics on the other.

Manning, Nikki (University of Montana), Kelly Dixon (University of Montana, Missoula), Pei-Lin Yu (National Park Service Rocky Mountains Cooperative), Mary Bobbitt (University of Montana, Missoula) and Ayme Swartz (University of Montana, Missoula)
The American West’s urban undergrounds are laced with mystique and lore. Well-known historic undergrounds exist in cities such as Portland, Seattle, and Sacramento. Tales exist of secret underground passages to houses of prostitution, Chinese opium dens, and prohibition-era alcohol smuggling operations. In some cases, archaeological evidence supports these stories, but it appears that many underground spaces were less nefarious than imagination might suggest. In Missoula, Montana, an urban archaeological survey was conducted to investigate subterranean archaeological features including steam tunnels, sidewalk voids, and a mix of mundane and clandestine basement spaces. Archival, architectural, and archaeological evidence, along with local collective memories were integrated to document extant physical remains of Missoula’s urban underground landscape and to explore how the political and social climate of early Missoula may have affected the use of space and the built environment. The results of this research is being utilized to understand how local cultural heritage can be used to develop preservation plans for the remaining physical features of urban planning and urban ecosystem transformations in the American West.

[241] Plenty More Fish in the Sea! An Isotopic Investigation of Hunting and Gathering at Grotta Continenza (Italy) during the Pleistocene/Holocene Transition
Hunter-gatherers increase nutritional yields per land unit by raising predation pressure on specific mammalian herbivores, and extracting more food from their carcasses, and/or by consuming a wider breadth of progressively harder-to-obtain plant and animal resources. To investigate the levels of specialization, diversification and intensification attained by Mediterranean foragers at the Pleistocene/Holocene transition, we undertook carbon and nitrogen isotope analyses on human and faunal bone collagen from Grotta Continenza. The isotopic data show that hunter-gatherers in central Italy acquired their dietary protein mainly from terrestrial herbivores feeding on C3 plants. Mesolithic individuals, however, have higher carbon and nitrogen isotope values than Upper Palaeolithic ones, due
to high levels of fish consumption by the former. The most likely sources of fish protein were trout of the
species Salmo trutta, introduced by the thousands to Grotta Continenza by its human occupants.
Numerous specimens of S. trutta yielded carbon isotope ratios significantly higher than those of fish living
exclusively in freshwater habitats, indicating that this trout was anadromous in the Mediterranean during
the Pleistocene/Holocene transition. Our findings have implications for understanding the productivity of
non-analogue Mediterranean environments for prehistoric foragers, as well as their potential for
intensification and diversification in resource exploitation.

Mansilla, Josefina, Carmen Pijoan (Instituto Nacional de Antropología e Historia Méxi) and Pedro
Bosch (Universidad Nacional Autónoma de México) [164]  Huesos humanos del México antiguo con diferentes pigmentos: análisis e interpretación cultural
En el México antiguo, se han encontrado huesos humanos con pigmentos rojos, azules, negros y
amarillos. El objetivo de este estudio es analizar, comparar y discutir los resultados de muestras óseas
preispánicas con distintos colores de Jaina, Campeche; Cueva de Los Frailes, Baja California Sur;
Chupicuaro, Guanajuato; Tlatelolco, ciudad de Méxi y Tlapacoya, Estado de Méxi. Es importante
conocer si los colores, analizando el contexto de los entierros, se deben a diagénesis por reacción del
pigmento original con otros elementos (compuestos) del entorno, si son producto de una coloración
como parte de un tratamiento mortuorio intencional, o también es posible que la coloración sea parte de
un proceso accidental. Las técnicas utilizadas para el análisis fueron: fluorescencia y difracción de rayos
X, microscopio electrónico de transmisión, de barrido y de fuerza atómica. Se demuestra que el pigmento
rojo en las muestras es hematina, sólo en Jaina el pigmento rojo resultó ser cinabrio. El amarillo de Jaina
fue originalmente rojo y las condiciones de su entorno lo transformaron a amarillo. El color negro en los
huesos de Tlatelolco es bitumen. Con base en estos resultados se proponen posibles explicaciones de
cómo los diferentes colores quedaron plasmados en los esqueletos.

Manzanilla, Linda (U Nacional Autonoma de Mexico) [21]  Mobility and Multiethnic Neighborhoods in Teotihuacan: The Teopancazco Case
Teotihuacan in Central Mexico was a huge planned settlement that housed a multiethnic population. In
ethnic neighborhoods in the periphery archaeologists have detected people and behaviors that refer to
Oaxaca, Michoacan and Veracruz. Nevertheless, another pattern is emerging where Teotihuacan
intermediate elites interact closely with people from Tlaxcala, Hidalgo, Puebla, Veracruz and other areas
in a way that suggests the presence of foreign elite individuals, specialized foreign craftsmen, foreign
carriers and porters, particularly in the Teopancazco neighborhood center excavated by Linda R.
Manzanilla and her team (1997-2005). In this neighborhood population, some stable isotope and
paleopathological results suggest that some of these individuals displayed dietary stresses when they
were young, and some may have come to the city with caravans moving between Teotihuacan and the
Gulf Coast, in order to have a better diet and more opportunities to work. The city needed labor and
presented itself as a land of opportunities and abundance. Nevertheless, some of these workers were
based in the neighborhood center perhaps as full-time craft workers, who often stood many hours in a
squatting position, sometimes with no exposure to the sun. Nevertheless, most of them did not return to
their homeland.

(Centre National de la Recherche Scientifique (CNRS) [201]  Why This revolution? Explaining the Technical Shift of the Late Mesolithic in Western Europe (7th
millennium cal B.C.)
During the 7th millennium cal B.C., a major change affected the composition of Mesolithic lithic industries throughout Western Europe (except the British Isles) and North Africa. This change took place rapidly 1500 years before neolithization and is one of the major mysteries of Old World prehistory. A wide range of archaeological analyses has shown the spread of a combination of new techniques, new types of tools, and new functions. In this paper we examine the links between these large-scale phenomena and the climatic events of the Holocene, as revealed by recent international research programs.

A Preliminary Analysis of a Sacbe System in Northwestern Belize

The scope of this research is to provide a preliminary geospatial and comparative analysis of an ancient Maya sacbe system associated with the Dos Hombres to Gran Cacao Archaeology Project (DH2GC) led by Dr. Cortes-Rincon in northwestern Belize. A small section of this linear feature was discovered at the end of the 2012 field season. During the 2013 field season, extensive survey and geospatial data collection was conducted on the sacbe system and the surrounding environment. Post-processed data analysis displays spatial relationships between the sacbe system, neighboring archaeological sites, and nearby natural resources. Interpretations of spatial relationships and labor estimates are hypothesized using statistical labor equations based on volumetric measurements for this linear feature. This data is compared to the current population estimates of the immediate vicinity in order to determine the size and availability of the required work force. This report also provides a regional comparative analysis of construction methods, raw materials, significance, and the use of these features by communities in the northwestern Belize.

Marino, Marc (University of Central Florida), Lucas Martindale Johnson (University of Florida) and Nathan Meissner (Southern Illinois University Carbondale)

‘Producer-Consumer’ Revisited: A Postclassic View of Stone Tool Production from Santa Rita Corozal, Belize

The ‘producer-consumer’ model of lithic tools between sites outside of the Belizean Chert Bearing Zone and the site of Colha has been well established for the Maya Preclassic to Terminal Classic Periods (C.A. 1000 B.C. - A.D. 800). Unfortunately, published lithic research on this region during the Postclassic Period (A.D. 900-1539) is scarce, and it is increasingly clear that producer-consumer models may be inappropriate for this time. A recent examination of 71 chert and chalcedony small side-notched points, point preforms, and 1,060 pieces of associated manufacturing debitage from one household residence at the Postclassic site of Santa Rita Corozal, Belize, reveals the presence of cortical flakes, prepared cores, flake blanks, and bifacial thinning flakes. Such information does not coincide with earlier producer-consumer models of Northern Belize that emphasize production occurring outside of site centers. The analysis of the complete Postclassic lithic assemblage from Santa Rita Corozal, including an additional 151 projectile points and associated reduction debris located throughout the site, demonstrates the need to generate new models of stone tool production for the Postclassic Period at this Northern Belizean locale.

Marino, Matt (Washington State University) and Justin Hopt (Washington State University)

Sacred or Secular? Two Perspectives from a Northwest Coast Shell Midden at Dionisio Point Locality, Galiano Island, B.C.

Studies of shell accumulations tend to focus on themes of subsistence practices and local ecologies or
ceremonial activities and deposition, but rarely do archaeologists give both ideas proper treatment. However, many middens in the Northwest Coast should be viewed as a conglomerate of different activities, both subsistence-based as well as ritual. This study examines midden deposits at Dionisio Point (DgRv-oo6) on Galiano Island, B.C., Canada, which contain both subsistence based features, seen in the thousands of intact and fragmentary fish and mammal bones, as well as ritual deposits seen in the form of human and dog burials. We consider multiple perspectives to examine this midden as both an area of refuse as well as an important ritualistic landmark. In this manner, we can gain information on local economics as well as ritual practices and how they articulate within the same depositional environment. This study thus presents us with an opportunity to reevaluate how archaeologists view middens on the Northwest Coast.

[28]  A Family Affair? Contextualizing Biological Relatedness within Roman-Period Mass Graves at Oymaagac-Nerik, Turkey

During the second and third centuries CE, multiple mass graves were incorporated into the hoyOk at Oymaagar;-Nerik, adjacent to the nearby Roman town, Neoclaudiopolis (modern day VezirkoprO). Bioarchaeological investigations of skeletal remains from two mass graves have thus far precluded interpersonal conflict as the cause of this sudden mass death, while ancient DNA studies are being undertaken to incriminate or eliminate possible pathogenic agents. Despite the commingled state of human remains, physiological profiles have been constructed from preserved skeletal elements. Additionally, biological relatedness has been inferred from non-morphological traits (e.g., os naviculare). Current research of the Oymaagar; skeletal remains endeavors to illuminate the historical circumstances surrounding (and following) this population decline. For this study, specifically, the demographic and palaeoepidemiological profiles of two mass graves, 7384:009 and 7484:021, are compared within the scope of the [biological] family. The family unit is considered and interpreted within the sociobiological, sociocultural, and sociopolitical environs of Roman Oymaagar;-Nerik and the wider Roman world.

[109]  Preliminary Report on New Excavations at Mirabib, a Middle and Later Stone Age Rockshelter in the Central Namib Desert, Namibia

This paper provides a preliminary report on new excavations at Mirabib rockshelter, a Middle and Later Stone Age site in Central Namib Desert in west-central Namibia. This site was first excavated by Beatrice Sandelowsky in the late 1960s, providing important evidence of prehistoric human occupation of the hyper-arid regions of western Namibia. These early excavations focused on the LSA remains and succeeded in demonstrating surprisingly early and complex patterns of pastoralist economy prior to 1500BP. Our excavations offer some new perspectives on these findings, providing additional chronological information through AMS and OSL dating. We also consider both cultural and geological processes of site formation, as well as the changing nature of site use activities over time. Finally, we discuss the Upper Pleistocene MSA archaeological remains, which were only analyzed ephemerally during the original fieldwork activities due to limitation in terms of available dating techniques. Our findings confirm a substantial presence of humans with MSA technologies in the late Upper Pleistocene with unique forms of foraging behavior, representing adaptations to extreme regional environmental conditions.

Marlowe, Frank (Lecturer, University of Cambridge, Biological Anthropology)
[73]  Hadzaland

The Hadza, hunter-gatherers of Tanzania, occupy an area of 4,000 km². There are about 1,000 Hadza who move several times a year. We researchers have asked individuals where the boundaries of Hadzaland are, a question which some can and do answer with ease and accuracy. One common feature is a lower elevation (< 1,700m), lower than that of surrounding tribes, where the Hadza say it is
too cold. One location that is special has giant rocks that when slapped with the hand sound a bit like timpani drums. The most puzzling thing is that there are several places in Hadzaland with rock art, which is no longer created. When asked if the art was made by their Hadza ancestors, some say yes, many others say they have no idea. One thing Hadza do sometimes mark is bee hives. When the hive is almost ready to raid, a man often finds a good rock to place in the entrance of the hive to block entry by other animals until the honey is ready. They appear to make a claim of ownership, but other men will usually simply remove the rock and take the honey without any qualms.

Marquardt, William (New Mexico Highlands University)

[42] Domestic Violence in the Ancient Puebloan World
Conflict, whether interpersonal or intergroup, often leaves its clear and dramatic imprint in the archaeological record, often visible in the form of burned structures, hastily abandoned sites, and traumatic damage to skeletal remains. Violence in the pre-Hispanic Southwest has drawn the attention of a number of archaeologists over the years. However, among many Ancestral Puebloan cultures, the context of violence is poorly understood. Recent studies have begun to refute the notion of “the peaceful Puebloans” that was popular among archaeologists in the 1930s. However, little research has been devoted to the cultural context of violence among these peoples. Perhaps the least studied aspect of prehistoric violence is that directed toward women. At a number of Ancestral Puebloan sites throughout the Southwest – such as the La Plata Valley of northwestern New Mexico – there is a high incidence of traumatic skeletal injuries among women. Why or how these women came to be the victims of such violence is unknown. The purpose of this research is to investigate the incidences of violence through time and across space and to better describe explain the context of violence against women in the Ancestral Puebloan world of A.D. 750 to 1350.

[116] Living and Hunting during the Mesolithic. Lithic Functional Analysis from the Cabeço da Amoreira Shellmidden (Muge, Portugal)
During the last decades, the Mesolithic shellmiddens of Muge (Central of Portugal) have been seen as the result of an intensive human ecological exploitation associated with the onset of the Holocene climatic shifts ca. 8200 ka cal B.P. Based on techno-typological patterns and artifact density from archaeological deposits, each shellmidden was linked to specific functionality, in a residential and logistic land-use strategy. Recently, new data from the site of Cabeço da Amoreira seems to show evidences of different diachronic functionalities and spatial organization, within and between sites.

One of the most interesting novelties is the presence of several archaeological horizons adjacent to the shellmidden deposit characterized by abundant lithic remains. In this paper we present preliminary lithic use-wear analysis from two loci: (1) shell mound and (2) one excavation area outside the midden, characterized by a rich archaeological horizon. Despite the initial idea that all human activities were conducted in the midden, this new data shows that surrounding occupation areas have been used as shellmidden support spaces. This data lead to new interpretations for shellmidden diachronic construction phases and intra-site settlement organization.

Marreiros, João [116] see Pereira, Telmo

Marsh, Laura (Stanford University), Isabelle Druc (University of Wisconsin) and Cesar Sara Repetto (Proyecto Arqueologico Chavin de Huantar)

Thin-section analysis yields information about the manufacture and origin of archaeological ceramic material. However, due to associated costs and destructiveness to samples, it is not feasible for overly extensive amounts of ceramic fragments. Therefore, careful selection of sherds plays a large role in determining the quality of the following analysis. In the case of the monumental center of Chavin de Huantar, Peru, the process of selecting samples for thin-section analysis to investigate ceramic origin and contact with contemporaneous sites began with choosing sherds for the preliminary macroscopic analysis. Key contexts were chosen based on the presence of Chavin-phase ceramics, diagnostic fragments, and various morphological and decorative traits that suggested significant styles or patterns of use or purpose. Sherds were analyzed for form, decoration, treatment, and other basic attributes. A digital USB microscope was then used to examine and photograph the pastes, which were then grouped
by similarities in matrix and inclusions. From within these groupings, samples with sufficient diagnostic information from the macroscopic analysis, large enough size, and enough plain area to allow for cutting without too much loss, were chosen for thin-sectioning, in order to achieve the most representative sampling of pastes possible from the contexts under study.

Marsh, Ben [41] see Johnson, Peri

Marsh, Anke (Institute of Archaeology, UCL) and Mark Altaweel (Institute of Archaeology, UCL) [257] Palaeoenvironmental Investigations in the Shahrizor Plain, Iraqi Kurdistan

In 2011, University College London initiated a project focusing on palaeoenvironmental research in the Shahrizor plain of Iraq, with University of Munich and University of Heidelberg, who are leading the archaeological survey and excavations of a large multi-period site respectively. The primary research goal of the project is to apply a multidisciplinary approach to bring forth new information on the region’s palaeoenvironment, history, and archaeology, in order to better understand how these three components interrelated and influenced the region’s social and socioecological development in the past. Before 2011, little palaeoenvironmental research had been done in Iraqi Kurdistan, and nothing regarding change during the Holocene in the Shahrizor plain. The Shahrizor stretches from the northwest to the southeast along the western edge of the Zagros and southeast of Sulaymaniyah between Arbat and Halabja. In order to better understand Holocene climate and vegetation change in the region, several programs were initiated, including trenching and coring, speleothem collection and analysis, and sampling and analysis of sediments and microfossils (particularly phytoliths). Preliminary findings are presented here, mainly derived from sedimentary and phytolith analysis of onsite and offsite contexts from the area north of Halabja, which formed part of a PhD research project.

Marshall, Charla (ISAS-UIUC), Cris Hughes (Department of Anthropology, UIUC), Timothy Pugh (Department of Anthropology, Queens College CUNY) and Ripan S. Malhi (Department of Anthropology, UIUC) [147] Mitochondrial Genetic Variation among Burials from the San Bernabé Mission, Tayasal: Preliminary Results from an Ancient DNA Feasibility Study

The 2010-2012 excavations of Tayasal’s San Bernabé Mission uncovered 28 graves, or sepulchers, buried beneath the church floor. Discovered in nine or more rows, these graves contained the remains of one or more individuals, and were possibly organized by kinship ties. Given the paucity of Spanish artifacts recovered from the San Bernabé excavations, it is likely that Colonial period Maya were the primary grave occupants, although persons with Spanish, African, and non-Maya indigenous ancestry might have been included among the burials as well. To assess the feasibility of ancient DNA (aDNA) research that may lead to insights into ancestry, identity and health during the Colonial period at Tayasal, we attempted to extract DNA from teeth from seven San Bernabé burials. We successfully recovered mitochondrial DNA from five individuals, which were assigned to Native American haplogroups A and C. A sixth individual yielded a mitochondrial haplotype indicative of European ancestry, although additional data are needed to confirm this result. Furthermore, our preliminary analysis shows that co-buried persons did not always share the same mitochondrial DNA. The larger implications of this study are presented, and future goals for the aDNA project are discussed.

Marshall, Maureen (University of Chicago) [291] “Sharing Death”: Double Interments in the Late Bronze Age South Caucasus

The Late Bronze Age (1500-1150 B.C.) appears to be a period of dramatic restructuring of political society in the South Caucasus with the sudden appearance of hilltop fortresses that demonstrate evidence of administration and ritual activity. Mortuary practices seem to be dominated by individual interments and examples of ‘warriors’ and ‘metalworkers’ that point to emergent socio-political complexity. Double and multiple interments have also been recorded, but are most commonly interpreted as “couple burials” or “mother and child” burials. Such interpretations imply a kinship system understood in terms of ‘marriage’ and birth. Yet, there are numerous examples of individuals with the same skeletal sex buried together as well as multiple interments varying in both age and sex. Drawing on anthropological perspectives that view kinship as transpersonal relations as well as the bioarchaeological emphasis on practice and lived experience, this paper discusses the double interment of two adult individuals in the Tsaghkahovit Plain, Armenia. Using an osteobiographic approach, I explore how
subjects 'shared death' and life in Late Bronze Age society.

Martin, Debra (University of Nevada/Las Vegas)

The tomb at Tell Abraq (c. 2200-2000 BC) was the repository for over 400 individuals of all ages and both sexes. Situated on the Persian Gulf near Sharjah and Um al-Qwain in the United Arab Emirates, the tomb contained the commingled remains of at least 276 adults and 127 subadults. Of the subadults, there was a relatively high frequency of premature (28%) and newborn (9%) infants in the tomb. This overview provides the demographic structure of the tomb population based on a detailed MNI study, and the complex nature of the mortuary program. Based on the overall MNI determined by the talus bone, observed versus expected ratios show that many long bones as well as hands and feet are underrepresented. We propose these can be accounted for by excavation and retrieval strategies. The mortuary program appears to be what Boz and Hager have described as being "primary disturbed". Grossly underrepresented elements such as the cranium could have been removed and used in other contexts. This late Bronze Age tomb is unusual in many ways and does not fit any Umm an Nar patterns.

[53] Animal Pathologies at French Colonial Sites in the Midwest: Case studies of White-tailed Deer at Forts St. Joseph and Ouiatenon

Investigations of large archaeological faunal assemblages often reveal unique incidences of animal pathology. Although interesting as curiosities, pathological specimens can disclose insights on past animal populations and the human groups that were exploiting these populations. Four specimens from the Fort St. Joseph (20BE23) and Fort Ouiatenon (12T9) sites illustrate incidences of trauma suffered by white-tailed deer (Odocoileus virginianus) at eighteenth-century trading posts that were inhabited by French settlers and their Native American wives and trading partners. Gross examination and application of micro-computed tomography shows a pattern of severely broken front legs on individual deer that survived their initial injuries long enough to permit bone healing and remodeling before the deer ultimately became the victims of Native American or French hunters. Specifically, environmental sheltering from predation, food and water availability in immediate surroundings, and fractured bone ends in reasonable apposition could accomplish functional healing through the downward pull of gravity, heavy limb weight, and limited movement. Individual diagnoses can reveal details about the traumatic injury, malnutrition, and/or infections, and the resiliency of the animal in surviving injuries that initially might be considered to be fatal.

[132] The Evaluation of Costly Signaling as a Motivator in Human Subsistence Behavior

The application of optimal foraging theory to the analysis of human subsistence remains provides valuable insights into variability in behavior over time. Analyses utilizing this theoretical framework often cite the caloric return rates of resource types as predicting prey choice. However, a body of literature within anthropology, biology, and economics known as costly signaling theory predicts that there are social benefits to individuals who communicate their fitness to an audience through the production of honest signals. If the acquisition and distribution of difficult to acquire resources meet these criteria, the fitness benefits of costly signaling via subsistence activities may also be an important consideration in understanding prey choice. Here I construct a formal signaling model and evaluate its predictions using ethnographic accounts of feasting. I then examine the archaeological implications to assess whether ecological conditions during particular periods of North American prehistory would have favored the signaling benefits of prey acquisition as an alternative to caloric return rates in motivating subsistence behavior.

[140] The Neolithic Demographic Transition in Mesoamerica and Its Implications for Early Farming Dispersals

In the Near East and elsewhere, the Neolithic Demographic Transition (NDT) refers to the relatively rapid
increase in population and population growth rate following a shift in subsistence economy from one based on foraging to one based on farming. In Mesoamerica, the NDT was a more gradual process that unfolded over the entire Formative period (1800 BC-A.D. 200). An analysis of published records of over 6700 prehispanic burials, focusing on changing proportions of juveniles 5 to 19 years of age, suggests that fertility rates rose steadily over the second and first millennia BC. The gradual pace of the demographic transition was likely related to the low initial productivity of maize. Comparison of our results with NDT patterns observed in other regions provides insight into the large-scale picture of the transition to agriculture in Mesoamerica, specifically models of early farming dispersals.

[283] **Evaluation of Geophysical Methods in the Detection of Toddler Sized Burials within the First Six Months of Burial**

Geophysical survey has become a major tool in the search for clandestine graves associated with missing persons cases. However, relatively little effort has been made in evaluating different instruments. GPR, magnetometry, resistivity, conductivity and susceptibility survey data were collected every 30 days for two research plots: an open grassy area and a wooded area. Each area contained five pig burials representing toddler-size (less than 50 pounds) remains and two areas of disturbance or false burials. The resultant imagery is evaluated in terms of relative utility in burial detection.

[290] **Cans of Worms: Explanation in Tsimshian Archaeology**

The distance between the fragmented and imperfectly sampled archaeological record and the grandeur of history can be spanned, as Ken Ames suggests, by rope bridges of entwined logical cables, including general and specific analogies. In Tsimshian archaeology the weakest of these are ethnographic analogies, although the weakness emerges from the archaeological analogy rather than the ethnography. In many ways, the ethnographic analogy is a chimera as the ethnographic subject is contemporary rather than historic. The archaeological expectation that the ancient can be understood in terms of the modern is, as many have noted, teleological. The deeper error, however, is the lack of explanation in archaeology for cultural continuity beyond the parameters of adaptation (both homeostatic and evolutionary). In contrast, the source of ethnographic data on history, the oral records of Tsimshian people themselves, provide clear scholarship on both the nature and causes of historical change. In this paper I outline the Tsimshian explanation for the emergence of their own ‘complexity’ and compare this to extant causal explanations in archaeology. The data are a best fit to the former, suggesting that orthodox archaeological explanations of these developments are, as many ethnographers have argued, vulnerable to ethnocentrism.

The Humid Pampa subregion of Argentina has been inhabited by hunter-gatherer populations since ca. 12,200 14C years BP. Archaeological research indicates that during the Final Late Pleistocene and the Holocene the areas that composed the subregion show differences in chronological trends as well as intensity of occupation. Also, models that proposed population continuity and/or discontinuity implying expansion, contraction, replacement or even extinction have been suggested. The discussion of these issues has been focused on specific lapses such as the early mid-Holocene and the early late-Holocene. In this work, a complete data base of all radiocarbon data available for the subregion is compiled, and temporal frequency distributions are used to assess the variations in the intensity of human occupation through time. Within this framework the above mentioned hunter-gatherer demographic processes and population dynamics are discussed.

[11] **Ceramic Technological Traditions in Coastal Ecuador**
The southern coast of Manabí province, Ecuador, has been the scenario of a long term research project focused on the complex interactions between humans and nature; in particular we are interested in the exploitation of resources through time in this highly environmentally diverse region. Our survey has identified more than 300 sites distributed in at least 4 broad environmental zones. For the later periods, domestic settlements have a tendency to concentrate alongside the coastal line and to spread throughout the riverine ecotones. Salango site 40, located in the riverine ecotone yielded, approximately 20 clay ovens, between complete and incomplete. From the site, a sample was selected to analyze ceramic technological traditions and food preparation traditions. A variety of approaches were used to recognize cultural dynamics: ethnoarchaeology, ethnography and material culture analysis. The results were surprising. Although, ancient technological traditions of pottery making have disappeared in the area, food preparation traditions have persisted throughout the centuries. Furthermore, food preparation traditions have undergone changes (as suggested by the ethnographic data) but they have been continuous for at least the last 2000 years (as suggested by the archaeological data).

Martinez, Marco (Archaeologist) and Dolores Davalos (MA Student at Tulsa University)

Today's Understanding of Casas Grandes' Architectural Variety

Recent investigations in the Casas Grandes area have led us to a new perspective regarding its architectural variety. In the past, the Paquime construction type was accepted as a norm for other types of pueblo construction inside the region. Now we can find other types outside Paquime; among its closest neighbors.

The first one is comprised by Paquime's thick-walled architecture described by Di Peso, the second one is a thin-walled construction type found in several sites inside the core area, like site 231; and the simplest architecture, a third type characterized by really thin walls. The former being found inside plazas, needs minimal construction. Using visual, descriptive and statistical comparisons to divide recently excavated Casas Grandes sites by their architectural differences, we will try to demonstrate the relationship between the three architectural types first described. Also, current chronological data and associated materials help us to point out chronological similarities and the short or long term use of such construction types.

As a result, we expect to find out that the region of Casas Grandes had a significant population growth in where the addition of temporal edifications in the sites involved was used in a time period.

Cholula y Cacaxtla; ciudades hermanas?

Cholula ciudad milenaria, con una ocupación casi ininterrumpida que supera los dos milenios, tiene una etapa compartida con la vecina Cacaxtla y por ende, esperaríamos encontrar similitudes en su arquitectura, cerámica y costumbres funerarias. Ya las fuentes tlaxcaltecas, entre ellos Muñoz Camargo, citan con frecuencia la relación existente entre Tlaxcala y Cholula en los años previos a la conquista. Así por ejemplo menciona el caso de diversos individuos que siendo de Tlaxcala, se fueron a vivir a Cholula, como una muestra de la relación que existía entre ambas ciudades. La etapa de interés corresponde al Posclásico Temprano, momento en que Cholula empieza a repoblar y a poblarse luego del abandono que sufrió al final del Clásico, representada en la ciudad por pequeños altares localizados encima de La Gran Pirámide y en su entorno inmediato, asociados a una cerámica que por sus formas y acabados resulta diferente a la del Clásico que le antecede y a la policroma que trajeron los grupos tolteca chichimeca que arribaron en el siglo XII y que se atribuye a los Olmecas Xicalancas, grupo que también pobló Cacaxtla; siendo a partir de estos elementos que trataremos de mostrar la similitud o discrepancia que existió entre ambas entidades.

The Ramifications of the Historical Romanticism of the Catalina Island Tongva

From giants to white Indians to Indian princess clutching the sides of a large stone bowl, explorer's journals, historical newspaper accounts, “scholarly reports,” and popular literature provide interesting depictions of the Catalina Island Tongva. Since 2007, the Pimu Catalina Island Archaeology Project has been collecting provenance and provenience information about Catalina Island’s archaeological collections. This research has uncovered some accounts that often paint an unrealistic and romantizced
image of the Catalina Island Tongva. This paper will describe some of these fanciful images and stories from a variety of sources and discuss how these representations have influenced the public’s perception of the Island Tongva and how they have derailed the expansion of scientific research surrounding the Tongva on Catalina and the mainland.

[197] Trajectories of Social Change in Prehispanic Honduras
This paper deals with evidence derived from the comparison of different social trajectories in regions of western, central, and eastern Honduras, which points to three common factors that stand out as crucial elements for understanding the development of social hierarchies in those regions: access to prime agricultural land, craft production and local exchange and interregional interactions. Each of these factors can be understood as components of two basic political strategies: economically or prestige-based ones. The articulation or combination of these factors, and the ability to connect economic and prestige strategies to each other, enabled the consolidation of permanent forms of social inequality in many regions of prehispanic Honduras.

Martínez, Jupiter (INAH-Sonora)
In this paper I discuss architecture and organic artifacts as material culture indicators that help us understand the Serrana communities of the Casas Grandes Culture in the State of Sonora, México. The data come from two sites: the cliff dwelling Cueva de Ochoa and the Bavispe site, both located in the municipality of Bavispe in Sonora. Our results lead us to reconsider previous perspectives that placed the state of Sonora as a peripheral area and to support an earlier model that sees major social complexity and interaction in the region. This research also leads to a greater understanding of the Casas Grandes ethnic identity and concludes that this ethnic group could be ancestral to the Opata people.

[200] Archaeology of Batacosa and Onavas valley in southeastern Sonora, Mexico
We intend to present the results obtained by the Proyecto Arqueológico Sur de Sonora, over six years of research in southeastern Sonora, Mexico, specifically in the Batacosa and Onavas valleys between the Mayo and Yaqui rivers.
We propose that Batacosa emerged as a local development resulting from the diversification of the Huatabampo and Serrana traditions at the beginning of the Middle Ceramic period, around 500 AD. and suggest that Batacosa continued to be active during the branching of the Serrana tradition into the Serrana Baja and Alta around 700 AD, keeping features from both traditions.
At Onavas, we have focused our work on the Casa Pima and El Cementerio sites, dating between 1474 and 1644 AD, and 943 and 1481 AD., respectively. While Casa Pima is a residential area, El Cementerio is a burial site where we have recovered more than 50 burials, some exhibiting cranial deformation and dental mutilation, characteristics which support our argument that this population had greater cultural affinity with coastal populations of northern Sinaloa and Nayarit. In this paper, we present an analysis of the material culture at Casa Pima and El Cementerio.

Martínez, Estela (Estela M. Mora)
[253] The Blue Stones Funerary Contexts in Prehispanic burials from Chalchihuites region, Zacatecas, Mexico
Agricultural groups settled the Chalchihuites region since the first millennium AD; these societies developed an intense lapidary production, crafted mainly on blue-green stones, motivated by the appreciation of these object, always associated to a high symbolic meaning. The economic activities, such as lapidary and the exchange networks for these and other products influenced deeply in the social complexity processes of these people. In my work, I will present the funerary contexts of individuals buried with such objects and analyze its transformation over time as evidence for social change.

Martínez Lara, Mario (Mario Martínez)  
[293]  Análisis iconográfico de los Once Señores de Cacaxtla  
Esta ponencia se deriva de un análisis iconográfico realizado a once esculturas que se encontraron en las inmediaciones del sitio arqueológico de Cacaxtla en el estado de Tlaxcala, México de manera fortuita en el año de 1998. La poca difusión y los escasos estudios sobre estas fue el principal motivo para llevar a cabo este trabajo y contribuir a las investigaciones arqueológicas que se realizan en este estado.

Las esculturas presentan una serie de elementos iconográficos que aluden a la propiciación de fuerzas fecundadoras y que además tienen similitudes estilísticas con otros sitios del periodo Clasico y Epiclasico mesoamericano como son Tajín, Teotenango, Monte Alban y particularmente Tetotihuacan. Los resultados del análisis permitieron la identificación de deidades y personajes asociados a un ritual cuya practica pudo ser común en diferentes sitios contemporaneos a Cacaxtla.

Por otro lado, se pudo inferir el posible uso y desacralización de las once esculturas resultado de los movimientos sociales importantes que se suscitaron en consecuencia de la caída de Teotihuacan. Este panorama sociohistórico pretende explicarse brevemente en esta ponencia, además de dar a conocer las esculturas, su importancia y significado a fin de abrir nuevas líneas de estudio enfocadas a esculturas de este tipo.

Martinez-Yrizar, Diana (IIA-UNAM) and Emily McClung de Tapia (IIA-UNAM)  
[63]  The Potential of Paleoethnobotanical Evidence in the Study of Teotihuacan Foodways  
Macro- and microscopic plant remains recovered from excavations at Teotihuacan over several decades contribute to an understanding of the subsistence resources available to the city’s inhabitants. However, associated contextual evidence may be inconclusive regarding the specific uses of the plants in question and, particularly, whether their presence or relative abundance indicates processing and consumption or the consequence of depositional processes. While the analysis of archaeological plant remains is necessarily an interdisciplinary endeavor, involving aspects of botany, ecology, ethnography and history among other disciplines, contextual archaeological evidence provides the matrix for interpretation. This presentation explores the significance of appropriate contextual evidence (e.g. activity areas, associated ceramics, lithics, etc.) and the potential complementary role of analytical techniques such as residue analyses, and isotopic signatures in faunal and human osteological remains as well as stratigraphic sediments.

Martirosyan - Olshansky, Kristine  
[20]  Masis Blur, a Neolithic Settlement in the Ararat Plain, Armenia  
The advent of the Neolithic period marks the beginning of one of the most significant changes in socio-economic and political development, yet this period is the least studied cultural phase in the archaeological sequence of Armenia. Until recently, the Neolithic period in Armenian was known only through sites discovered in the 1960s and 1980s, though the material from these excavations remains largely unstudied and unpublished. The fragmentary nature of archaeological investigations has not allowed us to construct a chronological sequence for the Neolithic period or to characterize the trajectory in the development of early settled communities in this part of the Armenian Highlands.

The Neolithic settlement of Masis Blur is a mound site located some 13 km to the south-west of the capital of Yerevan, in the Ararat plain. The first season of excavations uncovered 3 undisturbed architectural layers, complete with houses, hearths, fire pits, and an abundance of lithic, bone tool, and faunal assemblages. These layers date to the early 6th millennium cal. B.C. and are contemporaneous with two recently excavated Neolithic settlements in the Ararat plain. This talk will present some preliminary results, with a focus on geochemical analysis of the obsidian artifacts.

Marwick, Ben [214] see Kretzler, Ian

Marwick, Ben (University of Washington) and Tim Maloney (The Australian National University) [298]  Identification and Visualization of Lithic Reduction Pathways Using Elliptical Fourier Analysis
Ethnographic and archaeological research into stone artifacts in the Kimberley region of northern Australia has been dominated by investigation of the numerous reduction pathways that result in pressure flaked points. However, this focus on pressure flaked points has neglected to detect a range of other point reduction pathways in the archaeological record. Typically, sites in this region lack evidence of pressure flaked point production and so it is important to understand the processes that generate assemblages at sites without pressure flaked points. We analysed seven surface assemblages from southern Kimberley to determine if there are multiple reduction trajectories producing a wide range of retouched morphologies. We processed digital images to obtain outlines of their plan views. We applied elliptical Fourier analysis to the outlines of artifacts as a tool for discriminating between different morphologies and showing how they are related. This method does not require landmarks and therefore can accommodate significantly more complex and irregular shapes than other morphometry methods. The results show staged sequences of point production, resulting in pressure-flaked points as well as a wider range of direct percussion point morphologies and demonstrate the potential of surface assemblages for reduction sequence analysis.

Maschner, Herbert (Idaho State University) [246]  Band, Tribe, Chiefdom, State: Who Do We Appreciate?
Social complexity, intensification, group size, economy, hierarchy: terms used to measure and evaluate social evolution at all levels of society. Mike Jochim and I had many conversations on these topics and reflecting on them for the last 25 years returns one simple conclusion; that there is only one major transition in the history of human cultural evolution. The transition from mobile foragers to villagers, where people had a permanent place to keep their things and cohabitated full-time with unrelated neighbors, set in motion all of the social interactions that would eventually lead to states and empires – just at a larger scale. At this time social change took off at a rate that could not be tracked by biological evolution, and maintaining sociopolitical efficiency often trumped any attempts at subsistence / economic efficiency because we are simply not biologically adapted to live full-time with a large number of unrelated people. It was at this time that some of our deepest and oldest biological adaptations such as in-group out-group behavior, within-group cooperation, status competition, and territoriality were morphed into the social and ethnic dynamics of larger scale organizations.

Masinton, Anthony (University of York) [107]  It's Junk Until It Matters: Building Meaning from Visualization
One of the most important benefits of 3d computer modelling of archaeological and historical data is that it forces the researcher to interpret all of the available evidence in a concrete and systematic way. This frequently yields new insights and opens up new questions. The process of creating a visualization of the past is also, fundamentally, an imaginative one where meaning and subjective interpretation are key. Many archaeologists find this daunting, even risky. But, without this engagement with our visions of the past, our evidence and, perhaps, our interpretations will remain a disconnected assemblage. Drawing on a range of recent and ongoing visualization projects focused on medieval and post-medieval English buildings, the dangerous, provocative and valuable process of visualization will be explored.

In the Maya region, subterranean chultun features are most commonly associated with storage despite variability in form, context, and assemblages. To discern patterns among the variability, I examined the formation processes acting upon chultuns in the region, and identified three unique life history trajectories. These trajectories acted as comparative tools for the results of work performed in Chultun 2 at La Milpa, Belize. The formal attributes, context, and assemblage associated with Chultun 2, align it with a unique group of chultuns hypothesized to have served as symbolic features within the Maya cultural landscape.

[113] Shell Money through Time in the Maya Area
Multiple Contact Period accounts are clear about the use of shell beads as an all-purpose marketplace currency in the Maya area. This paper explores the archaeological evidence for shell money in the deeper past (Classic and Postclassic Periods). Identifying currency units from objects used purely for decorative or social purposes is aided by tracking variables such as standardization, relative scarcity, renewability, and long term continuity as these criteria are useful elsewhere in world history. The “bead” monies of the Colonial era probably referred to a limited range of suspended objects, particularly, olive shells and morphologically similar marine gastropods. I argue against classifying Maya shell monies as “primitive” as their use context is a poor fit for the explicit anthropological meanings of that term. Probable shell monies from Postclassic era Mayapan bridge the temporal gap of Classic Period objects and Colonial sources and facilitate the use of the direct historical approach.

[291] Using Household Bioarchaeology to Assess the Demographic Effects of Aztec Imperialism: A Kinship Study Based on Ancient Mitochondrial and Nuclear DNA from Xaltocan, Mexico
Between AD 1428 and 1521, the Aztec empire conquered numerous polities in the Basin of Mexico. At Xaltocan, an influential Otomi town, historical and archaeological evidence provide conflicting accounts of the demographic effects of Aztec imperialism. While colonial documents state that the Aztec conquest led to a replacement of the Otomi population, archaeological finds suggest a substantial degree of population and cultural continuity. To better understand the demographic consequences of Aztec imperialism, we extracted ancient DNA from 42 individuals unearthed during bioarchaeological research at Xaltocan. These individuals belonged to six households and included pre-Aztec and Aztec residents. We analyzed mitochondrial DNA sequences, 15 autosomal short tandem repeats (STRs), and 23 Y-chromosome STRs to help assess kinship relationships among individuals. We identified kin groups in pre-Aztec and Aztec burials, but no close biological relationships when comparing pre-Aztec individuals with Aztec individuals. Additionally, we found that the Aztec conquest was associated with a replacement of matrilines. These results indicate that a genetic shift occurred at these households across the Aztec transition, suggesting that Aztec imperialism might have led to important demographic changes yet substantial cultural continuity. This research illustrates how studies of kinship in household bioarchaeology can help address broader anthropological questions.

[276] ‘Missing Links’ and the War of the Worlds in Tiguex (1540-1542)
Although the link between conflict and sixteenth-century entradas has never been remote or ambiguous, Native-European combat in North America remains poorly documented archaeologically. Ironically, material evidence of major encounters in the American Southwest has been extant for nearly a century, but until recently went largely unrecognized. Our focus is on sites of conflict associated with the 1540-1542 entrada of Vázquez de Coronado and the Tiguex War in New Mexico – a sustained period of armed conflict between Southern Tiwa Pueblos and a large combined force of Spaniards and their Native Mexican auxiliaries. A new battle-related assemblage connected with this conflict is reported and arguments are presented to suggest it may be Moho - the site of a historically documented two-month siege in the winter of 1540-1541. We compare this assemblage with contemporary sites and entrada activities to better define conflict and other assemblage types. By examining new sites and older collections, we focus on how small components of the archaeological record contribute to understanding
Native-European interactions at a broader regional and inter-regional scale. Furthermore, we suggest how early, large-scale conflicts reoriented Native-Spanish relations with regard to warfare, defense, and settlement throughout New Spain during the later sixteenth century.

[160] Ancestral Presence and the Public Secret: Hiding the Dead in Plain Sight

The Straits Salish peoples of southern Vancouver Island built distinctive funerary petroforms for their ancestral dead. Based on the results of a spatial and visibility analysis of 420 funerary petroforms distributed in two neighbouring cemeteries, these monumental burials were often built at the threshold of perception. While notions of materiality and monumentality rely on the visibility of things, the unseen and the intangible have a power of their own. Secrecy magnifies reality and the concealing or controlling of access to forbidden places or things heightens their potency. These burials were active and powerful agents and shielding them from the day-to-day enhanced their power. Building these burials, as multi-layered ritualized acts of concealing the dead, was a process that produced a monument and memories retained by the living, even if they were associated with private knowledge or space. Secrets held in public trust entail knowing what not to know, and as something outside of regular discourse, they were invested with social power. As such, this act of concealment is also revealing. The dichotomous dead were both a source of fear and danger, yet retained a posthumous social, economic, and political life central to the process of history and place making.

[330] Cosmopolitan Living? Examining the Sugar and Rum Industry of the Costa Escondida, Quintana Roo Mexico

This paper examines our research into the history of the development of the sugar and rum industry in a remote region of northern Quintana Roo known as the “Costa Escondida” from the 1870s to the mid-twentieth century. Since 2009, we have been conducting archival and archaeological research at the site of Xuxub and several nearby plantations to acquire material evidence of what daily life was like for the people who lived at these sites and worked in the industry. Foreigners often managed these small-scale businesses with regional laborers on small ranches using relatively primitive technology and producing small yields. Despite the remote locations of these sites and small production amounts of sugar and rum, we have recovered a surprising number of artifacts imported from the U.S. and other countries, including luxury goods and construction materials. This paper will examine how the value placed on the crude commodities of sugar and rum combined with the benefit of coastal access may have allowed for access to cosmopolitan goods within the swampy mangroves of the north coast.

[339] The Origin of Mitote Ceremonialism in Postclassic West Mexico

Mitotes are a widespread and central element of indigenous ceremonialism in the Gran Nayar, a region encompassing parts of the modern Mexican states of Nayarit, Jalisco, Durango and Zacatecas. These round dances, known among such groups as the Cora, Huichol, Tepehuan, and Mexicaneros, are a part of ceremonial cycles that are closely tied to agriculture and the cultivation of maize. In examining the origins of present-day indigenous religion and ritual in West Mexico, many studies tend to examine archaeological data from the Formative and Classic period, such as art from Shaft Tomb cultures and the Teuchitlán tradition. While these earlier eras certainly are relevant, data from the Postclassic period (AD 900-1521) has been largely bypassed, undoubtedly due to the paucity of archaeological work conducted in the last 50 years, especially in the core Aztatlán heartland of Nayarit, southern Sinaloa, and northern Jalisco. This presentation explores some of the core ritual elements of contemporary mitote ceremonialism in the ethnographic and ethnohistoric literature, including Sun and Morning Star worship, and traces evidence of these elements in the archaeological record. This effort seeks to discern the historical origin of core indigenous religious practices associated with mitotes in the Aztatlán region during the Postclassic.

Ranching in Native Cultural Landscapes: Preliminary Faunal Analysis from Mission Guevavi

The colonial period in the Southwest has been framed and romanticized by Anglo-American Western expansion and the colonized/colonizer binary. While documentary and oral histories have helped to upend this Eurocentric paradigm, Southwestern archaeological and material studies have only recently begun to view missions through the lens of indigenous cultural landscapes inclusive of multiple and conflicting viewpoints. The Pimería Alta, a colonial geo-political region constituting southern Arizona and northern Sonora, was a complex cultural landscape; domesticated animals and their products were an important aspect in the economic relationship of indigenous groups and various colonial actors. Recent excavations at Mission Los Santos Ángeles de Guevavi, located near Nogales, Arizona, investigate the early period of the Spanish mission enterprise in the greater Southwest. This paper presents preliminary faunal data from the materials collected during the 2013 NPS and University of Arizona field school excavations of a midden associated with the mission complex. Initial interpretation of the faunal remains, with a focus on the O’Odham at Guevavi as the primary consumers and laborers negotiating regional demands, better reflects the reality of weak and intermittent European control of the mission and the power continuum of economic relationships between various indigenous groups and settlers.

Matisoo-Smith, Lisa (University of Otago)

Ancient DNA of Pacific Commensals– New Methods New Questions

New methods in DNA analyses, particularly the development of Next Generation Sequencing has opened up new opportunities for aDNA studies in general and provide new possibilities for zooarchaeological studies. However, regardless of the data that can be obtained from faunal samples, archaeological context and geographic sampling remains a critical issue. This paper will discuss how new methods and better sampling of Pacific commensals particularly when combined with other genetic and archaeological data can be used to tease out complex histories of Pacific settlement and interactions.

Matsumoto, Go (Southern Illinois University Carbondale)

Creation of Political Subjectivity in the Middle Sicán Great Plaza

Recent discoveries at the capital of the Middle Sicán state in the mid-La Leche Valley have led archaeologists to suspect that the state might have been governed and maintained by a federation of multiple elite lineages in competition or alliance. Underlying this new explanatory model are the documentations of the same architectural configuration and associated ceremonial activities among multiple ceremonial mounds (coined as “Pomac Mortuary Complex”). This architectural complex is characterized by a tripartite, concentric organization of (1) a platform mound, (2) an immediately associated cemetery ground, and (3) an open space for large-scale ceremonial activities. The last is a non-walled space in contrast to the Late Sicán walled plazas, and the complexes of Huaca Loro and Huaca Las Ventanas seem to be coterminous within what is known as the Great Plaza. This presentation focuses on the documented activities around Huaca Loro and discusses the sociopolitical significance of the Great Plaza.

Stable Carbon (δ13Ccollagen, δ13Ccarbonate) and Nitrogen (δ15N) Isotopic Shifts in Central Texas Hunter-Gatherers over the last 7,000 Years

The prehistory of Central Texas reflects hunter-gatherer occupations. Direct information on resource use, increasingly available through stable isotope analysis of interments, allows researchers in this area to investigate long-term processes of stability, change, and intensification. We present carbon and nitrogen stable isotope results from roughly 80 individuals, most of whom are adults. This sample spans roughly 7,000 years from multiple sites. At around 7,000 BP (Early Archaic), isotopic data show a mix of CAM/C4 and C3 plant and animal use. While sample size is variable, data show a gradual decline in CAM/C4 resource use over the next 4,000 years. Around 950 BP (Initial Late Prehistoric), little CAM/C4 resource
use is indicated. This trend changes in the Terminal Late Prehistoric period (700-300 BP) with isotopes indicating a dramatic diversification of diet. Isotopes from some individuals continue to have a C3 focus. Others show a mix of C3 and CAM/C4 resource use, and still others have a pattern consistent with a CAM/C4 coastal-based diet. This sudden diversity may indicate dietary change. However, as turnover rates for bone in adults are slow, it may also reflect changes in mobility and alliance structures at this time, with increased movement of individuals between regions.

Mauricio, Ana (University of Maine)

Los Morteros is a mound-shaped archaeological site, located on the Pampa de las Salinas, lower Chao Valley, north coast of Peru. Despite the aridity and apparent isolation of this milieu, Pampa de las Salinas seems to have been a very different environment in the past, judging from the evidence of an ancient and long history of human occupation. Just in the area of Pampa Las Salinas (~3 km x 6 km), 21 archaeological sites have been reported, most of which seem to be pre-pottery settlements. Previous investigations considered Los Morteros as a "stabilized dune" whose top was used as cemetery during Preceramic times. However, geo-radar explorations carried out in 2006 and 2010 by a team of the University of Maine indicated the existence of architecture covered by thick layers of sand. Within this context, a comprehensive investigation carried out by the Los Morteros-Pampa de Las Salinas project in 2012 has revealed a complex history of formation of this site, which includes the existence of mud-brick architecture with monumental characteristics. Geo-archaeological and environmental approaches have produced data that allow a general reconstruction of the transformation processes of the environment that hosted this early social development.

Maus, Mathew [139] see Riley, Jenny

Mavko, Jonathan (PIARA), Rebecca Bria (PIARA and Vanderbilt University) and Rachel Shea (PIARA and Purdue University)

This poster presents the architectural and spatial analyses of Middle Horizon (ca. 600–1000 CE) Chullpa-type mortuary structures at the site of Hualcayán in highland Ancash, Peru. This research reveals how the construction and modification of clustered chullpas and their exterior patios indicate changes in inter- and intra-group membership at Hualcayán during the Middle Horizon. A total of eight Chullpas—above-ground, free-standing stone ossuaries—clustered in two distinct groups were analyzed, noting several characteristics including entryway size and orientation, interior chamber layout, interior and exterior surface area, construction sequences, and construction quality, as well as their spatial relationships to one another and to other architectural features (walls, plazas, etc). Both chullpa groups indicate different phases of use and modification, and this evidence points to how people in the Middle Horizon restructured space in and around these chullpas to both accommodate new social relationships and mark difference between themselves and other lineage or sub-lineage groups. Furthermore, measures of architectural sophistication and investment within each chullpa group point to existing and changing social hierarchies in the ancient Hualcayán community. In this way, this research on mortuary architecture reveals new insights on changing social relationships during the Middle Horizon in the Ancash highlands.

Stings and Puffers: Ritual Fish Use at Tikal

The "cult of the sea" resulted in the inclusion of fish remains in dozens of votive caches at Tikal and other sites. Context suggests that these were more than simple offerings; rather, it appears that these may have been utilized as blood letters, for ritual envenomation, and possibly for other types of activities. The spatial and temporal patterning of these remains is discussed for the North Acropolis at Tikal. Stings show strong temporal and behavioral patterning, with bone imitation stings predominant during the politically strong era of the Early Classic, replaced by real stings during the Hiatus Period; further, bone replicas and real stings are rarely found together, suggesting a strong behavioral division between these two artifact types.
Puffer fish remains are largely restricted to the political downturn of the Hiatus Period, suggesting that these remains played a very different role in ritual, although their actual use is unclear.

**Holly Bend, Mecklenburg County, North Carolina: Two Centuries of Piedmont Architectural and Cultural History**

Recent excavations at this historic, National Register property have uncovered traces of the dependencies that surrounded this standing structure until recently. From the federal five bay frame construction to the exterior end fireplaces, Holly Bend was and continues to be an example of vernacular architecture. Changes in the economic status and agricultural practices of the Davidson and subsequent families are reflected in the construction and abandonment of outbuildings formerly surrounding the house. Elements of these changes are exhibited in the poster along with images of recovered domestic material culture.

**Mayfield, Tracie (University of Arizona), David Pendergast (University College London) and Elizabeth Graham (University College London)**

**Consumerism, Industrialism, and Agriculture: Consumption and Productive Practices at Lamanai, Belize, During the Nineteenth Century**

Very few historical-period studies have focused on the Mesoamerican lowlands and to this end, the relationships between people, material culture, space, and technology in this region are poorly understood. Clearly, archaeological and historiographical investigations are needed in order to add perspectives inaccessible by any other means, such as the make-up and internal nature of small-scale, colonial-administered enterprises, which appear to have dotted the landscape in an attempt to extract or produce raw materials such as logwood and sugar. Much like the history that came before European contact, colonialism in Belize was not a uniform movement. Maya, Europeans, and other groups such as Chinese immigrants and emancipated slaves of African descent were incorporating or rejecting objects, technologies, and spatial practices differently, depending on time and place. This presentation will explore the material, social, and technological dialectics active at Lamanai, Belize, during the nineteenth century when British colonists established a short-lived sugar plantation at the site. Previous archaeological investigations recovered data that clearly indicated the presence of materials associated with day-to-day behaviors generally linked to late-colonial industrial and residential activities such as cooking and eating, building maintenance and construction, health and hygiene, and sugar agriculture and production.

**La Necrópolis de El Caño. Nuevos aportes al conocimiento de las sociedades del istmo centroamericano.**

Recientemente se han descubierto en El Caño, valle de Río Grande de Coclé, región cultural "Gran Coclé", en Panamá, una necrópolis con tumbas de personas de alto rango fechadas entre el 700 y el 1000 d. C. Éstas son coetáneas a las halladas en el cercano Sitio Conte, cementerio en el cual Samuel K. Lothrop del Museo Peabody de la Universidad de Harvard y John A. Mason del Museo de Antropología de la Universidad de Pennsylvania descubrieron, hace ochenta años, la primera evidencia arqueológica de la complejidad de las jefaturas panameñas. La existencia en Sitio Conte y El Caño de elementos semejantes –basaltos columnares dispuestos en hileras, calzadas de cantos rodados y ricas tumbas- organizados espacialmente de forma similar a lo observado en Sitio Conte indica la existencia de un patrón funerario en el valle de Río Grande. Además de esta multiplicidad de sitios que entran muy probablemente en una dinámica regional de rivalidad competitiva entre grupos, la presencia de niños con ricos ajuares indica que entre el año 700 y el 1000 d.C. se encuentra el momento de máximo desarrollo, en lo que a complejidad se refiere, de las jefaturas del istmo centroamericano.

**Conservation Archaeology in Action: Using CRM Results for Long-term Research Programs, Land Conservation, and Outreach**

As the new field of cultural resource management was taking shape in the early 1970s, Bill Lipe in his foundational statement, "A Conservation Model for American Archaeology," rightly challenged archaeologists to understand that "all sites are rather immediately threatened..." not only from
development and construction, but also by the profession itself, especially as the business of doing archaeology became a growth industry. It soon became apparent that there was a need to balance the exploitative aspects of cultural resources management with a conservation ethic, where entire archaeological sites and even communities and cultural landscapes could be preserved in-place. Throughout our respective careers, we have embraced this ethic in the practice of cultural resources management, resulting in public policy for the protection of cultural resources, the creation and implementation of the regional Sonoran Desert Conservation Plan, nearly $30 million in public bond funding for archaeological site protection and historic preservation, and an innovative approach that we call Preservation Archaeology, which seeks to balance research, site protection, and public outreach.

Mazin, Anna (The College of Wooster), Olivia Navarro-Farr (The College of Wooster) and P. Nick Kardulias (The College of Wooster)
The Hohokam culture thrived in the Sonoran Desert of Arizona from roughly 300 BCE to 1450 CE. Hohokam pottery is divided into four general types: plainware, redware, buffware, and Salado polychrome. In this study I seek to identify who would have been responsible for ceramic production and consider how the organization of production reflects the structure of Hohokam society. I argue that the continuation and evolution of ceramic designs reflects the transmission of the craft from teacher to student. One may theoretically follow these lines of transmission by studying similarities and differences of design, and then use transmission as a proxy to trace larger social concepts, such as matrilocality or the political, social, and economic relationship between communities. Expanding on previous work in which I discussed Hohokam production sites and materials, I examine ceramic samples and ethnographic data for evidence of generational design transmission, and then utilize ceramic designs as a proxy to infer social patterns such as matrilineal descent.

[57] What Lies Beneath the Basketball Court? Community Archaeology and Managing the Dead
Sixteenth-to-eighteenth century missionization in Yucatan often included forced relocation of Maya peoples, construction of monumental church complexes, and burial of converts around the perimeters of churches. Mission churches are still highly visible today and the adjacent burial grounds provide a focus for studies of colonial disease/health, but little is known of the dwellings in which relocated Maya peoples lived. Archaeologists from UNC-Chapel Hill and Universidad del Oriente (UNO) formed PACOY (Proyecto Arqueologico Colaborativo del Oriente de Yucatan) to find and investigate colonial Maya dwellings. One locale that holds significant potential for this investigation is Tahcabo--an eastern Yucatec town founded in 1549 and still occupied today. During the summer of 2013, the mission complex and associated town features--such as rejolladas--were scanned, mapped and limited surface collection conducted. Town meetings and dialogue with community members revealed the layer of colonial burials beneath the town plaza to be a source of concern in trying to balance a respect for the dead with civic improvements (such as a basketball court). PACOY researchers and the community have now joined together to pursue techniques of mapping the perimeter of the burials to assist in managing the dead and to conserve cultural heritage in situ.

McCardle, Angela
[167] Finding Meaning in a Postclassic Obsidian Core Cache
This Paper examines an obsidian cache offering excavated from underneath the foundation of the southeastern corner of a Postclassic Maya structure in Flores, Guatemala. The cache consists of approximately 200 exhausted prismatic cores, 100 prismatic blades, and 10 flakes, all of various types of obsidian. The components of this offering were found arranged in a radiating circle underneath the structure floor in a concentrated area measuring 30 cm in depth. Post-excavation data collection consisted of sourcing the obsidian and documenting the measurements, degree and type of rejuvenation, presence and type of use-wear, and the number and variation of platforms, blade terminations, and blade scars for each artifact. This information is used to examine the core-blade technology responsible for creating this assemblage as well as to comment on procurement practices and the role of trade and polity interaction in the Postclassic Maya period. This paper will also explore the relationship these cores, blades, and flakes have with the structure they were found underneath and the kind of caching behavior
at play that resulted in this offering’s deposition. Analysis of this cache provides information on lithic technology, trade networks, and cache-structure behavior of the Maya inhabiting the southern lowlands during the Postclassic.

[84]  Parks, Piazzas, or Abandoned Lots? Archaeology of Outdoor Spaces in the Near Eastern Neolithic

Exploration of communities and community interaction in prehistoric settlements has traditionally focussed on architecture and buildings; however, a lot of activity would have taken place outside. People would have been cooking, talking, building, tending animals, weaving, sewing, and a million other daily tasks in the spaces between buildings and around the fringes of the village. These spaces have been largely ignored by archaeologists, however, and this means missing a big proportion of daily life. I look at the physical reality of the outdoor spaces at a number of Near Eastern Neolithic settlements and present a methodology for modelling the way people could have occupied and moved through these spaces. I also examine the evidence for activities that might have been taking place outdoors. This elucidates how people might have been interacting in these early villages and whether they functioned as parks, piazzas, or simply as abandoned space, and demonstrates how explorations of exterior space contribute to our understandings of the past.

McBride, Pamela (Museum of New Mexico, Office of Archaeological Studies)
[294]  Chuska Archaeobotany: From Rooffall to Floorfill, Plant Remains from Late Archaic to Ancestral Pueblo Contexts

More than 200 flotation samples were analyzed from data recovery conducted along U. S. Highway 491, documenting Late Archaic, Basketmaker, and Puebloan subsistence in the southern Chuska Valley. This data set offers opportunities for comparison to others in the region, including Chaco Canyon, Mexican Springs, and Twin Lakes, to name only a few. The maize assemblage, consisting of over 100 cobs and about 80 kernels, has the potential to provide especially intriguing comparative results.

McBrinn, Maxine (Museum of Indian Arts and Culture, Santa Fe)
[202]  Linda Cordell: Her Life and Legacy

Linda Cordell’s primary research focus remained where she began, on understanding life in the late, large pueblos of the northern Rio Grande. Her range of interests, however, was broad and deep and her influence equaled her interests. Over the course of a long career, she examined a wide range of archaeological research topics from landscape use and trade patterns to the possibility of priestly power at Chaco Canyon. Her long tenure as museum curator and then museum director led to an interest in museology. Her thoughtfulness about the lives of Native Americans, past and present, informed her involvement in questions of traditional territory, affiliation, and justice. Cordell’s understanding of the history of the profession in the Southwest influenced her actions and views. She energetically mentored young scholars in archaeology and anthropology, including many who were not officially her students. This presentation sketches Linda Cordell’s life and continuing legacy.

[197]  Sonzapote, Power and Authority at an Early Urban Center in Nicaragua

The Sonzapote site on Zapatera Island (Nicaragua) is well-known for dozens of monumental stone statues representing human figures, many of which are seated on thrones. Yet little attention has been paid to the archaeological context of the site, including the statues and associated architectural features. In 2013, a joint archaeological project involving the University of Calgary, Mi Museo (Granada), and the Universidad Nacional Autonoma de Nicaragua conducted preliminary investigations at the site. The objectives of the project were to map the architecture, inventory the existing mounds and monuments, and establish the archaeological context of the occupation. This paper presents the results of excavations at Mound 14, including both the construction history as well as post-abandonment use as a mortuary site. The revised chronology results in major changes to interpretation of Sonzapote within the regional politico-religious network.

McCafferty, Sharisse (University of Calgary) and Geoffrey McCafferty (University of Calgary) [153] Monumentality at Sonzapote, Nicaragua
Since its initial discovery in the late 19th century, Sonzapote on Zapatera Island has been famous for its monumental statuary. Published in 1886 by Carl Bovallius in Nicaraguan Antiquities, the many huge statues representing standing and seated figures have inspired diverse interpretations. Little, however, has been done in terms of archaeological research at the site to determine the cultural context of these monuments, resulting in more wild speculation than rigorous empirical understanding. In 2013 a National Geographic-funded project began preliminary investigations at Sonzapote that included a topographic map of the site center, an inventory of extant monuments, and excavations around Mound 14 which uncovered numerous burial urns as well as contextual evidence that tentatively dates construction to the Late Tempisque period (ca. 100-300 CE). This paper summarizes the monuments at the site, consisting of statues, petroglyphs, and utilized boulder work areas.

McCall, Grant (Tulane University), Theodore Marks (University of Iowa) and James Enloe (University of Iowa) [109] Update on the Middle and Later Stone Age Excavations at Erb Tanks, Namibia
This paper reports on our further fieldwork at Erb Tanks, a Middle and Later Stone Age rockshelter in west-central Namibia. Specifically, we offer updates on the dating of site through optically stimulated luminescence (OSL), the analysis of lithic and faunal remains, and studies of the site’s geological taphonomy. We also provide some further context for the terminal MSA painted stone plaque discovered during the 2011 field season, as well as other artifacts bearing traces of pigment. We briefly discuss the implications of these objects for other similar phenomena known from the region, especially the MSA painted plaques from Apollo 11 in southern Namibia. Finally, we close by considering the nature of cultural changes in terms of the organization of foraging and pastoralist economic systems over the course of the late Upper Pleistocene and Holocene. Our excavations to date offer some surprising insights concerning relationships between patterns of technological organization, mobility and settlement systems, and subsistence intensification. Specifically, we show several adaptive trajectories in terms of site use and mobility patterns that are consistent with increasingly specialized strategies for dealing with the hyper-arid environmental conditions of the Central Namib Desert gravel plains.

McClain, Maggie (Texas State University)

A Skeletal Marker of Agriculturalists: Investigations on Coalesced Porosity on the Patella

This research examines the frequency of coalesced porosity on the articular surface of the patella among prehistoric Native Americans. The five groups (n=180 individuals) examined in this study varied temporally (Archaic–Late Prehistoric) and geographically (Tennessee, South Dakota, and Texas), and practiced hunter-gatherer, horticultural, and agricultural subsistence regimes. This analysis found that coalesced porosity occurs at a high frequency among agriculturalists (41%), but at a low frequency among horticulturalists and hunter-gatherers (7–18%). Different subsistence regimes require certain repetitive physical activities, some of which leave particular signatures on the skeleton. Although previously considered an indicator of arthritis, coalesced porosity on the patella results from prolonged hyperflexion while kneeling, which places the patella in direct contact with the femur. Friction from the femur and localized pressure from kneeling on a hard surface causes destruction and pitting of the articular surface of the patella. The posture required to create this articular surface change is identical to the corn-grinding posture that is well documented ethnographically. This research indicates that subsistence activities involving long hours grinding corn or other grain results in coalesced porosity on the patella, and that a high frequency of coalesced porosity is a clear skeletal marker of agricultural populations.

McCleary, Alexandra (University of California, Berkeley)

Affective and Effective Objects: the Museological Odyssey of a New Mexican Accession

In March of 1897, artifacts ranging from samples of potter’s clay to local renditions of Catholic iconography from New Mexican Rio Grande pueblos were accessioned into the Smithsonian National Museum’s ethnographic collections. The perfunctory designations first ascribed to these artifacts have had an enduring and profound effect on their fate as objects of study, display, and cultural mediation. Using this accession as a guiding framework, I will assess how the construction of historical narratives and nominal cultural designations have come to shape the Institution’s ethnographic collections, and how they in turn are made to perpetuate such narratives. The Smithsonian Institution, whose age, depth, and breadth of material culture is unparalleled in the United States, provides a natural environment to study historical disciplinary trends and practices within the United States. While there is increased sensitivity to simplistic distillations of complex social relationships in contemporary archaeological study, museum collections are still influenced and structured by previously employed curatorial methods. A greater sensitivity to the potential biases associated with previous curatorial strategies will increase the effectiveness of museum-based research, leading to more accurate portrayals of daily life in post-contact New Mexico.

McClelland, John (Arizona State Museum)

Revisiting Hohokam Paleodemography

Archaeological evidence documents an apparent depopulation of the Hohokam region of Southern Arizona at the end of the Late Classic Period (A.D. 1350-1450). It is clear that major population centers were no longer occupied and many of the distinctive material culture traits associated with the Hohokam tradition seem to disappear. Possible explanations include migration, dispersion of the population into less archaeologically visible settlements, and wholesale population decline. The latter hypothesis gained currency partly because of a seminal study of paleodemography and health at the Classic Period site of Pueblo Grande in the Phoenix Basin (Van Gerven and Sheridan 1994). The authors reported very low life expectancy, a very high dependency ratio of juveniles to adults, and other indicators of biological stress, suggesting that the population was not sustainable. Reevaluation of the original demographic data, combined with new data from subsequent excavations suggests that overall life expectancy was in the expected range for prehistoric populations and that there is no evidence of a dependency crisis. Comparing Late Classic and Early Classic samples shows no evidence of a sharp decline, suggesting that we should look beyond health factors in trying to account for the disappearance of Hohokam traditions.

McClung De Tapia, Emily (IIA-UNAM MEXICO)
Landscape and Paleoenvironment in the Teotihuacan Valley, México: Questions, Data, Interpretations

The analysis of archaeological plant remains together with macro- and microbotanical materials from off-site stratigraphic profiles, contributes significantly to attempts to detect changes through time in past landscapes. Material evidence for past vegetation (groups of plants characteristic of a specific landscape) at different moments in time provide indicators for paleoenvironmental change related to anthropogenic factors, natural climate events, and the interaction of both. Recent research in the Teotihuacan region attempts to sort out the combined influences of human and natural events and processes as they were manifest in the landscape over a period of three millenia. However, no single technique alone offers sufficient evidence, nor is change easily understood within a strictly local or regional framework. It is argued that complementary suites of data offer better hypotheses and more satisfactory interpretations.

McClure, Sarah (Penn State) and Douglas Kennett (Penn State)

Agricultural Origins and the Behavioral Ecology of Niche Construction

Niche construction has become an important organizing concept in the study of agricultural origins worldwide. The concept brings focus to the intentional and unintentional manipulation of plant/animal species and their environments (e.g., terracing) within an evolutionary perspective. In this paper we consider the concept of niche construction within the framework of the Ideal Free Distribution (IFD), a model adapted from population ecology. We use this integrated framework to develop a dynamic model for the spread of agricultural economies, the subsequent intensification of farming systems and the construction of increasingly sophisticated ecological niches to feed growing populations.

McClure, Sarah B. [300] see Zavodny, Emily

Household Maize Beer Production in the Andes: An Ethnoarchaeological Investigation

Recent literature on the role of alcohol in the ancient world has shown that the production and consumption of fermented beverages played a key role in the organization of many prehistoric political and household economies. The study of alcohol as a lubricant in social dynamics is especially pertinent in the Andes where reciprocity is the primary form of traditional economic transactions. In spite of the fact that scholars studying ancient Peru have long acknowledged the central role that the production and consumption of chicha played in traditional Andean societies, surprisingly little information is currently available about how to recognize the loci of small-scale chicha production and consumption in the archaeological record. The premise of this paper is that the modern production and consumption of chicha in traditional settings can provide valuable interpretive information for archaeologists working in the Andes. In this article, we develop fifteen independent indices of household chicha production to construct a methodology capable of aiding archaeologists in the recognition of domestic chicha production and consumption in the archaeological record.

McCormick, Sarah (New Mexico State University), Kayla Hurd (Grand Valley State University) and Elizabeth Arnold (Grand Valley State University)

An Ethnoarchaeological Examination of the Utility of Tool Preparation Methods for the Production and Use of Bone and Antler Needles

Previous ethnoarchaeological research evaluated the ease and expedience of various preparation techniques of bone and antler for tool manufacture. Using both fresh and dry bone, specimens were soaked, frozen and boiled as preparation methods prior to fashioning into a variety of needles. Control samples were selected and exposed to no additional processing. The same was repeated for antler in both fresh and dry condition. No preparation method yielded a clear choice for ease of manufacture as it was possible to create usable tools in a timely manner in all cases. However, boiling and/or soaking as a means of preparation does not enhance (and may impede) manufacture of bone and antler tools. The new research presented here examines questions of use and utility of the artifacts produced. How well would each tool hold up to use over time? Which material would need or tolerate reshaping? Each bone and antler needle produced in the first phase of research has been utilized for leather working and single needle knitting (naalbinding). Size and shape of the needles were significant factors on duration of use (until breakage). Both qualitative and quantitative measures are used to evaluate and test the utility and durability of the tools.

Publicity, Pathways, and Production: Evaluating Regional Diversity in Settlement Patterning and Architecture in Northeastern Peru

Posic B, an archaeological complex in the cloud forest ceja de selva in the Department of San Martín, Peru, includes mound structures, raised pathways, and an extensive array of terraces laid out on an alluvial fan. Early colonial documents indicate that the inhabitants of Posic B were Chachapoya, a loosely defined ethnic group that inhabited the region in the Late Intermediate Period (A.D. 1000-1450). Chachapoya sites are characterized by ridge or mountaintop locations, elaborate houses, and lack of public space. Posic B is located in a valley, has few house foundations, and does have evidence of public space. There are 3 suggested explanations for the different settlement strategy: (1) it could be a region-specific adaptation by a Chachapoya sub-group (2) it could have been imposed by Inka imperial administration, or (3) it could be evidence that Posic B was inhabited by a third ethnic group, the Orimona. Each possibility assumes unique sociopolitical organization of the site. This poster integrates excavation and survey results from Posic B with a consideration of the regional networks in which site inhabitants participated, in order to evaluate the sociopolitical organization and social identity of Posic B society.

McCurdy, Leah (University of Texas at San Antonio)

Virtual Architectural Energetics: An Innovative Digital Analysis

Digital archaeology and virtual reconstruction, in particular, are sometimes pigeon-holed as practices that merely result in the creation of presentation images or displays with little value for archaeological research. Virtual reconstruction is a specific digital methodology that has and will continue to move beyond labels of superficiality and offer innovative means to analyze and interpret archaeological data. As an example, I will discuss my current research on ancient Maya architectural construction practices and how I plan to use virtual reconstruction to analyze the energetics of construction labor. While founded in the established literature on architectural energetics, this methodology transforms the analytical techniques for producing energetic estimates and allows for both synchronic and diachronic labor analysis. Virtual architectural energetics and other innovative digital methodologies are concrete examples of the great value digital archaeology offers modern research.

The Art of Science and the Science of Art

A hallmark of Marvin Rowe’s contribution to rock art dating has been the demonstrated importance of collaboration between chronographer and archaeologist. For science to be successfully deployed to understand how old rock art might be, the scientist must understand how the art “fits” culturally into the archaeological record. This paper explores the interface between science and art at a rock shelter site called Pinnip 5. One of the largest recorded assemblages in the Jilakurru Ranges, this site has numerous phases of art production with changing style(s), subject matter and superimpositions. There is also a suite of motifs here that could be part of a composition: a large snake interweaves itself across the panel, with numerous headdress figures and other unusual anthropomorphs. Thirty paint samples were collected from this site (including several replicates), making it one of the most intensively sampled painting sites in the world. This paper discusses the interplay of science and art – and details the highs and lows of AMS radiocarbon dating of a rock art assemblage in this detailed case study from Australia’s Western Desert.

McDonald, Erin (University at Buffalo)

Social and Political Organization in Late Bronze Age and Iron Age Ireland: Application of the Dual-Processual Approach to Settlement and Pollen Evidence

Traditionally, cultural complexity was viewed as a linear, forward-moving evolution from band to tribe to
chiefdom to state. In more recent decades however, archaeologists have begun to recognize cyclical patterns of socio-political organization in prehistoric societies, and the processes that influence change. Theories on political and social organization and complexity in pre-state societies, such as Blanton et al’s dual-processual theory (1996) and Johnson’s scalar stress theory (1982) may be applied to the evidence for socio-political and settlement organization in Ireland during the Late Bronze Age and Early Iron Age transition. Land-use patterns, as determined through pollen samples, can be linked with changes in economic, political and social organization (Plunkett 2007; Plunkett et al 2008: 182). Through Plunkett’s interpretation of pollen data, this paper explores the economic, social and political factors that may have influenced changes in the socio-political organization of communities during the Late Bronze Age – Early Iron Age transition in Ireland. The ultimate goal of this paper is to apply Blanton et al’s dual-processual theory to Plunkett’s interpretation of the Irish pollen data.

[315] Pleistocene Butchering of Bison Antiquus: Evidence from Palos Verde, California

In 2012, a Bison antiquus pelvis bone was found in a Pleistocene aged deposit of the Palos Verdes region of Southern California. In one location of the bone there is evidence of linear surface modifications that may be the result of prehistoric butchering. Here, we present the results of a project that sought to determine if these indentations were the result of human activities or from naturally occurring processes. Through high-resolution surface reconstruction, SEM analyses and replicas, our results suggest that these marks are best explained as cut marks made on the bone while it was fresh and with a stone tool. The results of this investigation contribute to our understanding of the subsistence of Pleistocene human populations of Southern California.

[27] The Liquid Plaza: Haucaypata, Cuzco

This paper opens up a new dimension on Inca plazas by considering how liquids flowed through, into and under these public spaces. The vertical conduit known as the ushnu played a key role in maintaining the circulation of liquid offerings. I take as a case study the Haucaypata Plaza in Cuzco where we have more direct, eyewitness descriptions available through the ethnohistoric documents than for any other comparable public plaza in the Andes. These accounts highlight not only the importance of moving revered objects from the Coricancha, but also the reciprocal flow of liquid libations via the ushnu into an underground channel leading back to the Coricancha. I will discuss when and why these ritual events took place in the agricultural calendar.

[161] Reconsidering the Reality of Southeastern Mesoamerica: Continuity, Diversity, and Inter-Valley Interaction in Western Honduras

The late fifth century AD was a time of rapid transformation in non-Maya Southeastern Mesoamerica. From this time forward, the landscape of western Honduras would become filled with increasingly complex polities and rising populations. So too is there evidence for a distinctive change in material culture, such as the development of widely shared regional polychrome ceramic traditions and the stabilization of obsidian exchange networks. Arguably, more than any other period in prehistory, it is during the Late Classic that a unique cultural identity emerges from this part of Southeastern Mesoamerica. In this paper we seek to answer the question, can we characterize the diverse peoples and communities of Late Classic western Honduras as belonging to a culture area of shared affiliation and concordant identities, or is “Southeastern Mesoamerica” nothing more than a geographic designation, which encompasses a diversity of strategies just different enough to defy uniform classification? To address this question we place the findings of our own research in the broader context of the long-term research projects conducted by our colleagues since the 1980s. In particular, we emphasize the inter-valley interactions among these polities to illuminate the shared and divergent paths taken by these communities during this period.

An Unusual Case of Burned Remains from Bahrain: A Violent Incursion?

Burned human remains dating to the Dilmun period are a rare occurrence in Bahrain. One such instance are the burned remains, found at the Qala’at al-Bahrain site in the 1960’s. Due to the unusual nature of the remains and their association with an extraordinary number of seals predating the Mature Dilmun style, the Qala’at al-Bahrain remains are thought to signify a confrontation between the immigrating Amorite tribes and the local population. In this paper we reanalyse the skeletal material in order to determine whether the remains were burned while in a fleshed, green or dry state. The results provide insight into whether the deaths of the individuals were contemporaneous with the fire event, indicating that the remains had been intentionally burned during or soon after conflict; or whether the remains were burned sometime after death, possibly indicating unrelated events. Two burned control samples, a modern cremation sample and an archaeological sample representing varying states of decomposition, are examined to evaluate burning characteristics specific to dry, green and fleshed remains. The resulting methods are applied to the Bahrain assemblage, allowing a more accurate and precise investigation of the burning event and the processes that act on skeletal assemblages following inhumation.

Modern Environmental Datasets and the Reanalysis of Cedar Mesa (Utah) Settlement Patterns

Modern geographic information systems and web-accessible environmental datasets have created an opportunity to supplement earlier settlement models and provide additional insight into Ancestral Pueblo occupation of the Cedar Mesa area of southeast Utah. The settlement pattern analysis published by Matson, Lipe, and Haase (1988) contributed basic understandings of the distribution of the many small dispersed sites on Cedar Mesa, and of the environmental factors that influenced these settlement behaviors. Unable to access the surplus of environmental data available today, the initial analysis tested only a small number of environmental variables and employed an environmental proxy if the desired variable data was unavailable. This project will compile geospatial data from the archived site survey records and a collection of geological, botanical and hydrological datasets to test site location relationships with an expanded set of environmental variables. Leveraging the temporal and site type classifications from the prior study, further analysis will assess occupational period trends and variation among site types.

Big Pots for Big Shots Revisited: Mound and Village Pottery from the Mississippian Site of Angel Mounds

In 1993, John Blitz authored an important article on the power of “big pots” in efforts by “big shots” to create and augment social ranking, elite control, and elite hegemony in Mississippian societies. Specifically, Blitz discussed episodes of feasting on mound surfaces at Lubbub Creek, evidenced by the overabundance of “big pots” when compared to pottery found in village contexts. As part of a larger dissertation project examining culturally-meaningful variability within plainware assemblages from the Mississippian site of Angel Mounds, Indiana (12Vg1), I revisited Blitz’s arguments by comparing pottery samples from village contexts and the surface of the second largest platform mound at Angel (Mound F). Compared to samples from the village, the archaeological record at Mound F was found to contain greater proportions of plain jars and decorated plates, fewer craft production artifacts, and a restricted range of vessel forms and sizes skewed towards large vessels (and missing small ones). While these findings are similar to those found by Blitz, my interpretation somewhat differs and focuses on the unique technological styles of pottery production found in Mound F samples, highlighting the roles diverse individual pottery and food producers played in building community-identity through collective action at Angel Mounds.

The GHEA Vision: Connecting Communities and Promoting Collaboration

The Global Human Ecodynamics Alliance (GHEA, www.gheahome.org) grew from an NSF sponsored meeting at Eagle Hill Maine in 2009. The Eagle Hill meeting was aimed at connecting research teams active in different world areas who were working to make the long term record of past human ecodynamics relevant and accessible to policy makers and the public. This was a high energy gathering, and produced Surviving Sudden Environmental Change: Lessons from Archaeology edited by Cooper and Sheets. This volume is aimed at practitioners and the wider public and is available as an inexpensive
paperback or can be freely downloaded. This embodies the spirit of open scholarship, effective use of
cyberinfrastructure, and community engagement in sustainability science and education at the core of the
GHEA effort. GHEA is open access, web-based, participant structured, and has no governing structure. It
has grown rapidly and GHEA projects have attracted external funding, including an NSF Research
Coordination Network 2012-16 that has sponsored a series of workshops promoting cross-regional
comparisons of our completed long term human ecodynamics experiments of the past, developing
models and visualization tools, and going beyond outreach to engage local communities in heritage
rescue and education for sustainability. Join the Alliance and contribute!

[232] Sweet Misery: Labor and Power at the Chatsworth Plantation Sugar Mill

The LSU Rural Life Museum conducted Phase III data recovery excavations at the sugar mill portion of
the Chatsworth Plantation site (16EBR192) now in Baton Rouge, Louisiana from January to June 2013.
Chatsworth Plantation existed as a sugar producer along the banks of the Mississippi River from the
1840s until the property was sold at a Sheriff’s sale in 1928. The purpose of this poster is to explore the
question of whether the highly technical nature of sugar mill machinery, as well as the temporal
constraints of sugar cultivation in Louisiana, provided the workers with a degree of power. Research is
still ongoing and all results are preliminary.

McGuire, Randall (Binghamton University)

[237] The Cult of Quetzalcoatl and Late Prehispanic Religion in the Southwest US and Northwest
México

One of the things that distinguishes James Neely’s career is that he has done research in both the
Southwest/Northwest and in Mesoamerica. As an undergraduate student at the University of Texas, he
taught me not to regard the two regions as clearly bounded separate entities. The late Prehispanic period
(CE 1300 to 1450) in the southwest of the United States and the northwest of México witnessed the
spread of Quetzalcoatl iconography across the region in several related but distinctive religious
movements. These movements embraced Mesoamerican iconography and presumably cosmology but
realized it in distinctive ways. We see this iconography on polychrome ceramics, wall murals and rock
art. Southwest/Northwest peoples clearly expressed the symbols of the Cult of Quetzalcoatl in these
media but they executed them in a style distinct from Mesoamerica. This comparison of shared symbols
realized in a distinctive style becomes a metaphor for understanding the relationship between the two
regions. By the time of the Spanish conquista in the 16th century, only one of these religions, the Pueblo
Katsina Religion, survived. This paper will examine the relationship of these religions to Mesoamerica
and how differences in this relationship might account for why one survived and the others disappeared.

[166] Following the Cat-tail Highway: Geophytes, Digging Sticks, Formed Flake Tools, and
Paleoarchaic Expansion in the New World

Most scholars view the earliest inhabitants of the New World as either specialized hunters or generalized
foragers, both perspectives subject to an often strained and incoherent framework of subsistence,
technology, gender, work organization, and land-use. A much more parsimonious approach recognizes
the energetic potential of geophytes, particular cat-tail (Typha latifolia), and allows us to re-imagine how
these early populations organized their flaked stone technologies with regard to the subsistence efforts of
both men and women; how these groups might have gained a toe-hold in the New World; and how they
may have expanded so quickly in such an unfamiliar environment.

McIntosh, Brandon

[113] The Archaeofauna of Isla Cilvituk: Socioeconomic Niche Construction in a Lowland Maya
Lacustrine Environment
The archaeofauna of Isla Cilvituk, a Postclassic (A.D. 900-1520) Maya site in the state of Campeche, Mexico, offers a unique opportunity to understand differential subsistence and economic strategies across the Postclassic Yucatan. With significant ecological diversity found throughout the peninsula, the production of empirical data from the zooarchaeological record can provide a solution to what Kitty Emery has referred to as the “ill-defined Maya diet.” It can also provide a contextual framework through which the evolution of prehistoric human behavioral ecology may be interpreted in terms of resilience following the so called “Maya Collapse.” In this paper, the archaeofauna assemblage of the inland lacustrine site of Isla Cilvituk is compared to sites closely connected geographically to the macro-economic core near coastal regions during the Postclassic Period. An account of differential faunal biodiversity across sites from various ecological regions will provide context for how people at Isla Cilvituk utilized their local environment to sustain daily life and participate in market exchange. Such comparison should highlight differential niche construction strategies across the Maya landscape. It is possible that the Maya at Isla Cilvituk extracted commodities specific to their local ecosystem to remain socially, politically, and economically relevant during the Postclassic Period.

McKaig, Rachael (University of Wisconsin-Whitewater, Instituto de Estudios Peruanos)

[285] Material Wealth and Socioeconomic Connections in the Lurin valley – Panquilma and Pachacamac as a Case Study

This paper will focus on comparing the different interpretations proposed not only for Panquilma itself, but also for other Late Intermediate and Late Horizon Period sites in the Lurín Valley. Through the analysis and interpretation of the material goods and other artifacts found at Panquilma and Pachacamac, along with consideration of existing hypotheses of Lurín Valley life, a hypothesis for a material wealth connection will be made. If such a connection between Panquilma and Pachacamac did exist, it will be determined if it is also possible that there existed a material wealth inequality that favored Pachacamac, which could have helped form a socioeconomic hierarchy that strengthened Pachacamac’s role as being central to Lurín Valley life during the LI-LH periods. In addition, an analysis and comparison of the materials found in both central and peripheral household compounds at Panquilma will be done to determine whether or not there were material wealth inequalities in the domestic sector which might have created a complex social hierarchy within the community itself, mimicking the previously posited larger socioeconomic organization. This work will resume the debate on issues such as chronological sequences, social organization and power relationships in the Lurín Valley during the LI-LH periods.

[160] Move Over Salmon: New Perspectives on Indigenous Fisheries along the Northwest Coast

For many Indigenous peoples, the right and ability to fish is inseparably linked to their history, social relations, economy, and physical well-being. On the Pacific Northwest Coast, salmon are an iconic genera that have greatly enriched archaeological perspectives on the importance and antiquity of these linkages. However, the emphasis on salmon has been disproportionate relative to the rich mosaic of other species, particularly small fish that pass through conventional screens. Here, we report on zooarchaeological data compiled using fine mesh screening from over 170 sites from Alaska, British Columbia, and Washington to provide proxy measures of Northwest Coast fisheries over the Holocene. We observe that herring (not salmon) are the most ubiquitous and abundant fish in the majority of zooarchaeological assemblages (NISP) indicating an under-recognized importance to ecosystems and Indigenous peoples on the Northwest Coast. Analyses of temporal variability in 50 well-sampled sites reveals that herring exhibits consistently high abundance and consistently low variance within the majority of sites. We conclude this archaeological dataset reflects a higher and less variable mean abundance of herring prior to the onset of industrial fisheries and provides a new ability to explore regional and temporal variability in Indigenous fisheries on the Northwest Coast.

McKee, Arlo and Charles Frederick

[264] Site Formation Processes at the Murvaul Creek Caddo Site

Archaeological sites situated in the upland sandy mantle of East Texas often show complex postdepositional alteration. Buried site components are commonly identified and attributed to bioturbation or eolian processes. The Murvaul Creek site (41PN175) is a small Middle-to-Late Caddo
settlement located on an upland ridge above a broad stream valley in Panola County. Although the ground surface is relatively flat, a portion of the site has been buried by sandy sediments. The geoarchaeological studies, sponsored by the Texas Department of Transportation, focused on understanding the causes and timing of site burial. Multiple dating techniques were employed that suggest that site burial occurred immediately following the abandonment of the site and continued through the early historic period.

McKillop, Heather (Louisiana State University) [85]  The Role of the Sea in the Rise of Maya Civilization

The sea was integrated into the social and economic lives of the inland dynastic Maya as a supplier of coastal salt and other less critical marine resources, as a platform for transportation of goods and resources across various distances, and as a source of stingray spines and other ritual paraphernalia and symbolism basic to Maya ideology. Sea-level rise has submerged many coastal sites on the mainland, offshore islands, and underwater in the Maya area, leaving them invisible to research. The expertise of the maritime Maya in navigation provided a degree of autonomy from the hierarchical organization of nearby inland city-states, leading to heterarchical organization. I evaluate the importance of the sea for trade during the Preclassic, the role of inland trade of coastal salt during the urban expansion of Classic period Maya city-states in the southern Maya lowlands, and the flexibility of the coastal Maya to re-orient their allegiances with the rise of northern polities during the Postclassic. Case studies from the trading ports of Moho Cay and Wild Cane Cay and the Paynes Creek salt works in Belize are used as a platform to examine broader patterns for the Maya region.

McMahon, Kate (Howard University) [111]  “A Sufficient Number”: The Historic African American Community of Peterborough in Warren, Maine

Warren, Maine is located in the midcoast region of southeastern Maine. The small town has a long history that is intrinsically linked to the maritime activities of the region, which began in the mid-seventeenth century. Sometime around 1782, Sarah Peters was brought to Warren as a slave on a ship owned by Captain James McIntyre. After slavery was outlawed in Massachusetts in 1783/1784, Sarah successfully sued for her freedom and married a man named Amos Peters. Together, they raised a large, mixed-racial family, and settled near South Pond, a good distance away from the main village. By the 1820s, they had their own school district, were part of the Baptist church, and had a good deal of land. Their population peaked in the 1850s and 1860s, with as many as eighty-two mixed-race people living in Peterborough. This paper focuses on how African American and mixed-racial communities were able to establish themselves in maritime northern New England in the years prior to the Civil War, particularly during the antebellum period. Peterborough is a case study toward understanding African American communities outside of the plantation setting, and their relationships between agriculture and the sea.

McManamon, Francis (Center for Digital Antiquity) [239]  RBS to CRM (1974-2014)--Continuing and New Challenges and Opportunities

CRM (Cultural Resource Management) was a new term in the early 1970s, but its foundation is in the concerns about the protection of archaeological sites that developed in the late 19th/early 20th century and continued with the development of emergency/salvage archaeology in the mid-20th century. CRM continued (and expanded) the conservationist approach to archaeological resources, as well as some methodological and technical approaches. One substantial change with CRM has been the focus on project planning. Most of the contemporary archaeological investigations in the US are tied to some aspect of CRM. Topics related to CRM, e.g., professionalism, quality of results, sharing and preservation of information, costs, etc. are important to all American archaeologists. Most, professional archeologists support conservation as the appropriate treatment of the in situ archaeological record. Operationally this approach has the goal of managing archaeological resources for long term preservation, yet allowing prudent, justifiable use of the resource for research. There is general agreement that the network of
professional archaeologists in the various sectors of the discipline, e.g., public agencies, CRM firms, and academic settings, and the statutes, policies, regulations, and guidelines that protect archaeological resources are important to maintain and, preferably, strengthen.

[70] Composite Three-Prong Censers From Caves in the Maya Lowlands

Initial investigations of the Chiquibul River cave system in southwestern Belize in 1984 and 1986 included an archaeological reconnaissance. One area in Actun Kabal was named the Ledge of Offerings because it contained a large quantity and variety of artifacts. The assemblage included elements of the lowland Maya variety of composite three-prong incense burners first described by Stephan F. Borhegyi in 1959. He recognized that separate elements recovered in the 1930s from San Jose, Belize were actually components of a single vessel. This paper discusses the distribution of these censers in caves in the lowland Maya area.

[191] Negotiating Identity at Río Amarillo: Preservation and Resilience from the Late Classic to the Postclassic Period

Investigations at Río Amarillo, located in the eastern section of the Copan Valley, have documented changes over time in architectural forms, settlement choices, and the origin of trade items. Within its ceremonial core Late Classic structures and artifacts demonstrate the influence of Copan while a residential group to the north embodies a mixture of influences including those of the interior of Honduras. The site’s Classic period inhabitants embraced important aspects of the ideology and identity of the great Maya city, including the ritual use of a censer lid in the form of K’inich Yax K’uk’ Mo’, the first Copan king. Late Classic contexts contain Ulua polychrome and Copador ceramics echoing patterns found in Copan’s center. A wall, likely built during the Terminal Classic, demonstrates a distinctive change at the site, where inhabitants went from a town with few defenses to a more fortified center. Some scholars have suggested that the Valley was completely abandoned between the Classic and Postclassic periods, however it is unclear if this occurred at Río Amarillo, or whether the loss of Copan’s influence instead brought about a change in settlement choices for the inhabitants and a return to practices found in the Early Classic period.

A gradient magnetometer detects archaeological anomalies by measuring perturbations in the earth’s magnetic field caused by variations in terrain magnetic susceptibility. However, many years ago, Tabbagh suggested that short-spacing, dipole-dipole electromagnetic instrumentation that directly measures near-surface susceptibility should offer some interesting advantages. These include: 1) Excellent spatial resolution combined with reasonable depth of exploration (instrumentation with one-meter intercoil spacing provides both spatial resolution and exploration depth of the order of one-half meter). 2) Simultaneous measurement of terrain magnetic susceptibility and electrical conductivity (the conductivity has two useful components, normal DC conductivity and a component arising from soil magnetic relaxation effects). 3) Ability to directly detect changes in susceptibility of a horizontally-layered earth (approximate layered earth-response calculations are simple and a two-layered earth can be identified either by using either a single-spacing instrument in both vertical and horizontal dipole modes of operation or using a dual-spaced instrument). 4) Survey speed is comparable to that of a single-unit gradient magnetometer. 5) Direct susceptibility measurement provides improved survey interpretability due to freedom from response from remnant magnetism and independence from geomagnetic latitude effects. Several case-histories illustrate use of this technique to identify archaeological features associated with early French and Acadian settlements.

Breathing Life into the Village: Microhistories and Residential Genealogies of Domestic Life on Inishark, Co. Galway

Although widely recognized as an important topic in Historic Archaeology, surprisingly little research has examined the evolution of coastal villages after the Irish Famine. Drawing upon archaeological excavations, archival research, and historical documentation, this presentation explores the spatial interweaving of human action that reshaped the early 19th to mid-20th century village of Inishark, Co. Galway, a historic fishing village off Western Ireland that was abandoned in 1960. Integrating historical ordnance survey maps dating to 1838 and 1898, a 2008 village map, and LiDAR imaging with archaeological survey, we are able to reconstruct shifts in village patterns, residential densities, and land use.

Kulkalgal and Tudugal: Geopolitical Manipulation and Domination of Torres Strait Islander Social Networks

The tropical waters of Torres Strait abound in marine resources but terrestrial resources are less pervasive. The Kulkalgal people occupied the relatively infertile and drought-prone sandy cays of the Central Islands in contrast to fellow Torres Strait Islanders who inhabited the resource rich Western and Eastern Islands. High investment survival for the Kulkalgal centred upon water conservation, inter-island mobility, importation of garden produce, and social network development and domination. To help mitigate terrestrial resource vulnerability, the Kulkalgal orchestrated a regional polity and cemented a vast and complex web of social alliances and trade relationships spread across 700km of seaspace. To obviate political vulnerability, a sub-group of the Kulkalgal, the Tudugal, manipulated the regional exchange system by capitalizing upon their privileged access to marine resources and manufacturing shell valuables that became the primary means of purchasing imported and highly prized sea-going canoes which underpinned Torres Strait Islander society. Economic, social and political control and security was further enhanced by introduction of a headhunting ritual cult across the Central Islands and ascendancy of the Tudugal as the most feared warriors across Torres Strait.

McPeek, Kirstie

An Analysis of Ammunition Found at SCAI-39, Santa Catalina Island

The coast of Los Angeles Pimu/Catalina Island has been occupied for more than 8,000 years. Early European explorers dropped anchor in the beautiful Isthmus Cove and forged trade relationships with its inhabitants. While always portrayed as peaceful encounters, one object type that would logically reveal the unabridged nature of this trade relationship is spent and unspent ammunition. This presentation provides a discussion and analysis of the metal ammunition found at the village of Nājququar (SCAI-39) on the Catalina Isthmus based on material from excavations by Schumacher (1876) and UCLA (1969). Both spatial and chronological considerations aid in understanding the nature and extent of the relationships with European explorers from 1602 through the 1800s.

McTavish, Rachel (University of Wisconsin-Milwaukee)

Upper Mississippian Large Mammal Butchering Practices: A Case Study from Langford Sites in Northern Illinois

The focus of this paper is an analysis of how people use a diverse subsistence economy, engaging in agriculture, hunting, gathering, and fishing practices. Choices relating to large game hunting may hold important implications for understanding group interactions within the same ecological region, and relates to culinary preferences and environmental adaptations. People using Langford ceramics occupied the northern Illinois region for 300 years (circa A.D. 1150-1450) before disappearing from the archaeological record. However, the full nature of their subsistence economy remains in doubt. This analysis focus upon the utilization of deer and elk by these groups using data recovered from the several Langford sites located in the Upper Illinois River Valley and its tributaries in northeastern Illinois.

Means, Bernard (Virtual Curation Laboratory)
[152] **Promoting a More Interactive Public Archaeology: Archaeological Visualization and Reflexivity through Virtual Artifact Curation**

The Virtual Curation Laboratory at Virginia Commonwealth University was established in August 2011 with funding from the Department of Defense’s Legacy Program. Since its establishment, the Virtual Curation Laboratory has created hundreds of 3D digital artifact models from a wide range of archaeological sites located in the eastern United States, as well as printed plastic replicas of many 3D digital models. Some have questioned whether our efforts and those of similar projects are curiosities or novelties with little to contribute meaningfully to scholarly research or public engagement. In this paper, I will argue that 3D digital models and printed replicas allow for new ways of visualizing the past, while preserving the actual artifacts themselves. These forms of archaeological visualization enable the broader public and not just a narrow band of researchers to dynamically and meaningfully interact with rare and fragile objects in ways that would otherwise not be possible, empowering their own contributions to interpreting and understanding the past.

[42] **Exploring Virgin Anasazi Settlement Patterns and Community Structure in the St. George Basin, Southwestern Utah**

Archaeological research on the Virgin Anasazi has expanded tremendously during the last 30 years. However, the vast majority of this research has been primarily concerned with answering basic cultural-historical questions, including those related to chronology, the basic characteristics of material culture, and subsistence strategies. As a result, our knowledge about more complex aspects of the Virgin Anasazi culture, such as social organization and integration, community structure, and interaction and exchange, lacks the depth and resolution available for most of the Puebloan region, and the Greater Southwest in general. Despite these caveats, there is a vast amount of data available documenting the Virgin Anasazi cultural sequence capable of addressing the more nuanced complexities of the Virgin occupation and greatly advancing our understanding of the Virgin Anasazi and their place in the history of the Southwest. Using a GIS-based model, we explore settlement pattern(s), landscape use, and community organization from Basketmaker II (300 B.C.–A.D. 400) through the end of the Virgin sequence in late Pueblo II/early Pueblo III (A.D. 1150/1250) based primarily on survey-level data from the many compliance projects from the Virgin Anasazi region, and specifically from the St. George Basin.

Medina, Paulo (Boston University) and Mario Giron-Ábrego (Boston University)

[70] **Mesoamerican Caves: Supernatural Ideas, Real Places**

In their 1979 publication, “Pathways Into Darkness” MacLeod and Puleston formulated the first model for the cosmological significance of caves. They applied the widely accepted model of a three level universe onto the Popol Vuh. Then they equated their work in Petroglyph Cave directly to Xibalba and the underworld. In recent years, many of the fundamental premises of the model have come under attack. Recently, Nielsen and Sellner Reunert have argued that the layer model of the universe was introduced by the Spanish and is not a Pre-Columbian indigenous concept. In addition, advances in cave archaeology by James Brady and others have suggested that caves are far more closely associated with an animate earth rather than the underworld. This paper challenges the very concept of caves as “portals.” Instead it argues that the notion of a portal is a Western concept based on the idea that god exists in a different dimension. Thus, the way to connect with the supernatural is through a portal. For the Maya, on the other hand, supernatural figures are much more immediate and real. The cave is the Earth Lord’s stone house. The Maya enter and are in his presence.

Medina, C. Lorena

[309] **The Importance of the Secular Clergy during the Sixteenth Century in Guerrero State, Mexico**

At the beginning of the sixteenth century, the American continent and its inhabitants were immersed, as it has been called by Miguel Leon-Portilla, in a encounter of two worlds; two worlds with a vast cultural differences, differences that at the same time found analogies in the historical process among them. Thus, the territory called Mesoamerica was conquered by the Spanish in both military and religious terms. In the religious aspect is important to note that while much of the evangelization was the responsibility of
the regular clergy, it is also important to mention that the secular clergy reinforced and formed an important part of that process. Thus, the present disclosure denotes different aspects involving the evangelization process by the secular clergy in the state of Guerrero. The evangelization procedures by the secular clergy as well as their interactions with indigenous groups will be raised. Foregoing, within the policies of the government of New Spain, the rules establishes by the Archdiocese of Mexico and the entrenched relations with the regular clergy.

[177] A Preliminary Analysis of Surface Soils at Emal, Yucatan, Mexico
Surficial sediments, local depositional environments, and inter-and-intra-site variations in soil profiles were evaluated in the field at Emal between June 17th and July 10th, 2013. Emal is located at the very northern edge of the Yucatan Peninsula. The site was constructed on a promontory that extends into an inland estuary, Rio Lagartos, that is delimited from the Gulf of Mexico by a Quaternary barrier island. Surface soils were sampled to a depth of 80 cmbs across the Emal landform using an AMS split-tube auger and taken from a broad range of contexts. Sediments were described in the field according to USGS and NRCS guidelines. Soil salinity was measured using an electrical conductivity meter and preliminary analysis of salinity and surface soils indicates potential areas for salt production at Emal. Furthermore, spatial analysis of surface sediments indicates three main soil classes were present; beachhead (Bh), Lower Platform (Lp) and Upper Platform (Up). Lp and Up soils presented darkened organic horizons with charcoal and sherds to depths of 80 cmbs and may potentially indicate the presence of a hortic horizon or mollic epipedon. These data help inform our understanding of salt production and subsistence at this long-occupied coastal site.

[176] Locating Kellogg’s Tavern; Prairie Way Station and Frontier Battlefield during the Black Hawk War 1832
This presentation will discuss the recent attempt to locate “Old Kellogg’s Place”; a pioneer settlement and frontier tavern located on the edge of America’s old Northwest frontier. Functioning as an early frontier institution for decades, this stop over on the Peoria-Galena trail would host two separate engagements between Illinois militia and native forces during the Black Hawk War of 1832. This presentation will discuss the conflicting images of the Black Hawk War, past and present, and its importance to the establishment of Midwest Statehood and further national territorial expansion. Contextualized at the Kellogg’s Grove settlement, the investigation for this frontier settlement elucidates the nature of Native-Anglo relations in 1830’s Illinois. Despite documentary evidence, as well as local knowledge and lore (including the graves of American combatants and a stone monument commemorating the battles), the true location of Kellogg’s tavern and the accompanying battlefield may still be unidentified.

[147] The Economics of Point Manufacture and Factionalism in the Postclassic/Contact Period Petén Lakes Region, Guatemala
The Late Postclassic (A.D. 1400 - 1525) and Early Contact Periods (A.D. 1525 - 1697) of the Petén Lakes region are marked by intensified political restructurings including hostilities, alliances, and factional competition among local polities. This paper examines the role of political geography and its impacts on lithic production through a technological systems approach to chert and obsidian small projectile
weaponry. New research that includes resampling techniques and Social Network Analysis (SNA) indicates that the Chak'an Itza of Nixtun-Ch'ich', the Itza of Tayasal and Quexil, and the Kowoj of Zacpetén had complex methods of raw material procurement for points that brought certain ethnopolitical groups into exchange networks with one another while pushing others apart. A macroscopic analysis of the technological styles of arrow points among Petén polities reveals interesting patterns in manufacturing design, including the invasiveness of flaking, blank selection, blank orientation, and preferred morphology. Distant connections to the Xiu, Itza, Chetumal, Dzuluinicob, and Chuj polities are also explored in terms of point production and their potential interactions with Petén groups. Such information adds to anthropological literature by focusing on the complex intersection of technological systems, micro/macro-regional exchange, and ethnopolitical factions.

**[253] The Technological Analysis of the Turquoise Objects from the Great Temple of Tenochtitlan**

In the offerings of the Great Temple of Tenochtitlan in the Basin of Mexico, the Aztecs buried thousands of turquoise pieces at different constructive stages of this building beginning AD 1325 until AD 1520. The majority of them were inlays assembled in complex mosaics, like disks, ornaments of certain Nahua gods, and parts of chert knives and scepters. With the compositional analysis with UVF, XRF, FTIR, and PIXE, we know that almost all of the bluish-stones were chemical or real turquoise from Northwestern Mexico and perhaps the American Southwest. But, where these objects were produced and with which tools and techniques? The aim of this paper is to show the technological analysis applied on the turquoise pieces from Tenochtitlan, using experimental archaeology and the characterization of the manufacturing traces with SEM. As results, we identified three lapidary traditions at Tenochtitlan: one is related with the Mixtecs, another is non-Mesoamerican, and the last one shares the tools and techniques of the Tenochcan Imperial Style. Finally, we will compare them with turquoise objects from Mixtec and Huastec sites, the Chalchihuites region, Sonoran settlements, and the American Southwest, in order to confirm and discuss their places or workshops of origin.

**[24] The Last Time This Happened: The 1930s Carnegie Program of Funding Paleoindian Research**

The Cramer endowments, targeting as they do a specific scientific problem and supporting the archaeological and interdisciplinary work of more than half a dozen institutions, are both extraordinarily generous and virtually unique in the annals of archaeological research in North America. But not entirely unique: in the 1930s the Carnegie Institution of Washington invested several tens of thousands of dollars into research at Late Pleistocene archaeological sites, support that was vital at a time when the country was in the depths of the Great Depression. The Carnegie funding fueled a decade-long explosion of research and knowledge that formed the basis of our understanding of North American Paleoindians in the second half of the 20th century. The success of that program owed much to the vision of John Merriam, then President of the Carnegie Institution, and to E.B. Howard, whose seminal work at Clovis convinced Merriam of the benefit to supporting interdisciplinary research in this arena.

**[209] Testing Projectile Performance and Diagnostic Impact Fractures on Replica MSA Basalt Points**

This experiment aims to establish whether: 1) basalt points record diagnostic impact fractures when used as weapon tips, 2) impact fracture patterns on basalt differ to those on "high quality" raw materials, and 3)
if large, triangular points similar to those from the early MSA can function as arrow tips. Despite the wide occurrence of basalt in East African MSA assemblages, basalt has not been experimentally tested for impact fracture preservation. We compare macro-fractures on basalt arrow tips with impact damage patterns that have been consistently demonstrated in experiments on flint, chert, and quartzite. We also test assumptions that MSA points cannot function as projectiles and whether commonly used size categories for spears, darts, and arrows (derived from ethnographic collections of known function) actually correspond to functional limits. Our experimental points have tip cross-sectional areas and tip cross-sectional perimeters larger than known arrows, but comparable to MSA assemblages. We assess their projectile performance using penetration rate, penetration ratio, and durability. Our experimental points were found to function as projectile armatures and to exhibit impact damage. Although basalt is often neglected in functional studies, we suggest it can contribute important data for understanding early MSA behavioral innovations.

Ballcourts, Ceremonial Centers, and Trade Routes in the Manialtepec Basin of Oaxaca’s Central Coast

This paper reports on the results of a recent survey of the Manialtepec Basin, located on the Central Pacific coast of Oaxaca, Mexico. The Manialtepec Basin is a small coastal pocket surrounding the 1640 ha Laguna Manialtepec. The basin has only limited arable land, but it is the endpoint of the permanent Manialtepec and Chila rivers, both of which may have been important inland-coastal transportation corridors during the Pre-Columbian era. A brief reconnaissance and one rescue excavation in the 1970s identified several sites with mound architecture and carved stone monuments. The Proyecto Arqueológico Laguna de Manialtepec (PALM) was designed to re-identify sites from the earlier study and provide greater detail on regional settlement patterns in the precolumbian era. The results demonstrated the Manialtepec Basin had relatively dense settlement from the Late Classic period through the arrival of the Spanish. Several sites with modest monumental architecture—including ballcourts—were identified. The site of Bajos de Chila, site of the 1970s rescue excavations, was relocated, and further information was recovered about this important Formative period coastal site. Finally, the region may have corresponded to an ethnic or economic boundary, based on variability in the ceramics across the survey area.

The Initial Peopling of Continental Aisén: Problems Faced, Recent Results and Research projections

This paper summarizes recent research conducted to elucidate the characteristics of the initial occupation of central northern Aisén; framed within the early settlement of Central Patagonia. Essential to this endeavor was modeling the environmental conditions during the last 19,000 years through integrating palaeoecological (sedimentary cores) evidence, geomorphological analysis, and the archaeological record of Cisnes and Ñirehuao basins (44°30’-45°30’S). These activities focused on contextualizing previous archaeological evidence gathered at Baño Nuevo 1 (10700 cal yr BP onwards) and El Chueco 1 (11500 cal yr BP onwards) with new information gathered through a search program at stratigraphic and surface locations. Lake Shaman and El Embudo sediment cores provide detailed records of major changes in effective moisture and temperature throughout the Holocene. Comprehensive maps and field measures of the extent of major geoforms (proglacial lake shores, moraines, erratics) provide indicators for areas available for human occupation at the Pleistocene Holocene transition. Surface findings at Pampa Coichel and stratigraphic excavations at Baño Nuevo 15 offer new archaeological datasets with material evidence for human occupations starting at 10650 cal yr BP and allow characterizing an intermittent, though recurrent initial occupation of northern Aisén. FONDECYT grant #1130128.

Mendha, Muhammad Ali (Texas A&M University)

Fauna and Identity at Goat Springs Pueblo

Only limited research has been conducted in the Rio Abajo region regarding the social dynamics of its people. In this project I hope to further our understanding of the Rio Abajo region using data from Goat Springs Pueblo (LA 285), a site consisting of 250 rooms near Magdalena, New Mexico, overlooking the southern Rio Grande valley. This pueblo, located on a trail connecting Zuni and Rio Abajo villages, was
occupied at least two times during the late Pueblo period (A.D. 1300 - 1680). This project examines the mammalian and avian remains found within the middens and room blocks of Goat Springs Pueblo during the 2011 and 2013 excavations to help understand the identity, economy, and ritual practices of the inhabitants of the pueblo, including their response to Spanish occupation at the village. I will address questions regarding changes in diet and activity involving the use of faunal remains by identifying species and by using a variety of methods of analysis.

Mendoza, Zoila (Native American Studies Department, University of California, Davis)

[120]  Contemporary Indigenous Pilgrimage: An Approach to the Andean Sensory Model

Using the example of pilgrimage among Quechua-speaking inhabitants of Cuzco, Peru, I explore the role of the senses in the predominant form of knowledge and memory in Andean culture. I hypothesize that the keystone of such a form of knowledge and memory is the intrinsic relationship between the visual, auditory, and the kinesthetic sensory experiences. Understanding this allows us to explain why Andeans have chosen music, dance, festivals, and other kinds of public performances as privileged forms of social action throughout history. I look closely at the dance troupes that walk for three days and two nights to the sanctuary of the Lord of Qoyllorit’i (Lord of the Shining Snow) accompanied by the incessant music of flutes and drums.

Mendoza, Rubén (CSU Monterey Bay)

The recent publication of Robert Carneiro’s “The Circumscription Theory: A Clarification, Amplification, and Reformulation” provides an essential point of departure for assessing the role of resource concentration in prompting social complexity. Like Carneiro’s 1970 treatment of the classic concept of environmental circumscription, in which demography and conflict are construed as fundamental to that panoply of processes culminating in the rise of the state, the monopolization of circumscribed and critically vital resource deposits is deemed central to the formulation of the compound chiefdom, and by extension, the incipient state. Such a model provides a particularly cogent framework for understanding those socioeconomic and political dynamics that underlie the rise of the ancient state of Teotihuacan, México. By extension, this study proposes that that modicum of “environmental redundancy” characterizing the ecology of Mesoamerica’s Gulf lowlands prompted resource strategies culminating in the politico-genesis of dispersed Gulf lowland compound chiefdoms, and segmentary states or heterarchies. Ultimately, the heterarchical configuration of the Gulf lowland “states” was born of a reciprocal pattern of highland-lowland interdependence (mediated by way of the formation of pan-regional export alliances or Gulf lowland cartels identified with transacting strategic ventures) with the burgeoning populations of the hierarchically-organized paramount highland polity of Teotihuacan.

[151]  Reflections on the Development of and Future Directions for State CRM Programs

Passage of historic preservation and environmental protection laws in the 1960s and 1970s, coupled with the Cultural Resource Management and Airlie House conferences in 1974, all contributed to the creation and recognition of what is now commonly referred to as cultural resource management (CRM), an important and applied facet of archaeological research. Each SHPO (State Historic Preservation Officer) is tasked with carrying out the management and preservation of the state's archaeological resources. These goals present significant challenges to each SHPO program. This paper will review a selection of strategies that programs have employed in order to achieve such critical management goals as protection, preservation and public interpretation of archaeological resources; forming good working relationships with archaeological practitioners; and forging support from the archaeological community and decision makers. There will also be some consideration of "Where we go from here?" with ongoing, as well as new, issues and challenges facing state CRM programs.

Analysis of a Classic Period Multi-Use Tomb Assemblage in Southern Belize

Southern Belize is typically considered geographically and culturally peripheral in Classic Maya prehistory. Although researchers have documented the development of a "southern Belize style" in terms of architecture and material culture, to date very little systematic work has been undertaken to better understand mortuary behavior in the region. In 2012, excavations at Uxbenka documented two tombs with stepped entryways in the site's L group, located adjacent to the Stela Plaza. Although looting destroyed most of Tomb L1, systematic excavations of the intact Tomb L2 yielded a large skeletal and artifact assemblage, comprised of over 10 individuals and approximately 30 ceramic vessels.

The present research utilizes skeletal and dental data, ceramic analyses, isotopic data, architecture, and contextual data from Tomb L2. We suggest that Tomb L2 was deliberately constructed to be easily accessed, and was repeatedly used for both primary and secondary burials throughout the Classic period. It may have functioned as an important location for ancestor veneration at Uxbenka. Although tombs with multiple individuals are not unknown in the Maya area, tombs with stairs for entryways are far rarer both in the region and the greater Maya area.

Investigation of Stone Features in Context of Past Interpretations

The investigation of archaeological features constructed of stone in the Southeastern United States has a history that can be traced almost to the beginning of archaeology in the region. Current interpretation of the wide range of stone feature types has been informed through excavation, ethnographic record, as well as speculation. Because some stone features are the result of ritual activity, and may contain human remains, interpretation of these features for regulatory purposes requires careful assessment. The results of investigations into stone features and subsequent regulatory application have varied across state lines in the past. Because of this, field methods and interpretations of stone features deviate from state to state. This paper presents case studies on how the history of stone feature interpretation affected interpretation of sites for Cultural Resource Management work in Alabama and Georgia, and how it may affect archaeological interpretation and preservation.

Working with the Public at Crow Canyon Archaeological Center in Southwestern Colorado

Crow Canyon Archaeological Center was established in 1983, as a non-profit center for long term archaeological research that involved the public in the study of the prehistoric sites. Children from 4th grade through high school and adult participants come from across the country to attend week long programs, where they are taught about the archaeology of southwestern Colorado and the southwestern US through experiential education programs and participation in field excavations and lab work. We stress site preservation and archaeological ethics to all groups. American Indian involvement is also part of our mission. Our Native American Advisory Group advises and provides native perspectives on our programs and research projects. Our board provides financial support, advice and advocacy for archaeology and Crow Canyon in their home communities. Our president and leadership team meets with U.S. and state politicians to encourage governmental support of archaeological research, site preservation and curation. We collaborate on projects and grants with our local repositories, often borrowing artifacts for new or additional studies, thus highlighting the fact that curated artifacts and records continue to be valuable for future research.

Climatic and Anthropogenic Causes of Erosion at Uxbenká, Belize

Uxbenká is a small Maya polity located in the Rio Blanco Basin of southern Belize. This paper outlines a landscape evolution model that incorporates geomorphology, pedology, paleoclimatology, and paleoecology to better understand variations in erosion rates to investigate human-climate-landscape interactions within the basin. Alluvial terraces on the lower Rio Blanco record 9000 years of stratified
deposits and can be considered the inverse of fluctuation in basin-wide erosion rates. Accumulation rates in alluvial terrace deposits vary in relation to the availability of basin-wide hillslope sediment. Periods of landscape stability and pedogenesis result from relatively drier conditions and/or limited inputs from anthropogenic landscape modification. Conversely, greater precipitation and/or increased anthropogenic deforestation produce landscape instability. Fluctuating erosion rates and the consequent accumulation of over-bank flood deposits on the lower Rio Blanco are reflected in a series of buried soils in a 4 meter deep profile. The timing of these fluctuations is bracketed by a five radiocarbon dates. The results indicate that following Early Holocene stability, erosion rates were highest beginning in the Middle Holocene coinciding with human colonization of the region and continue through the historic period with a return to stable conditions in recent decades.

Mesia, Christian (Museo Nacional de la Cultura Peruana)

Convincing the Local and the Foreign: Political Strategies at Chavin de Huántar

Excavations at Chavin have determined that between 1200-500 B.C., the Wacheqsa sector was extensively used and occupied. The archaeological record in this sector bears evidence of two convincing strategies developed by the authorities of Chavin, one aimed towards gaining local support and the other aimed towards gaining the support of elites from outside of Chavin. Large feasting events were material manifestations of power and prestige, a symbol of labor organization and access to resources. Chavin offered different types of wealth to different classes of people. Elites from outside the Conchucos area came to Chavin in order to be initiated in the Chavin religious system and legitimize their authority; they obtained the wealth of authority, and authority became a commodity. On the other hand, inhabitants of the Wacheqsa sector worked for the ceremonial center, gaining access to resources most likely provided by the authorities of Chavin in exchange for their labor; in addition they obtained religious fulfillment by their participation in the maintenance of the temple.

Gaddafi to Post Gaddafi, the Changing Status of Libyan Archaeology in the Media

Libya is the site of remains of at least Phoenician, Greek, Roman and Berber settlements however, under the country's 43-year rule by Muammar Gaddafi, archaeological work by outsiders was often limited or curtailed. During the recent revolutionary activities in Libya, including the overthrow of Gaddafi, some archaeological sites were endangered by the conflict. Now, after the rise of a new government, archaeology can seemingly return to normal pathways. How did the media present the state of archaeology during Gaddafi's reign? How important were the archaeological sites considered during the conflict? And now, how do the media represent archaeology in Libya? Through an evaluation of newspaper and magazine articles covering all three time periods, a picture of how the media views archaeology in Libya will emerge.

Holocene Climate Variability across Mesoamerica: The Monsoon and Other Drivers of Change

Although dominated today by summer precipitation associated with the seasonal migration of the ITCZ and the North American (or Mexican) Monsoon (NAM), the area encompassed by the term Mesoamerica experiences very different climatic regimes that display differential responses to forcings such as the PDO and ENSO (originating in the Pacific) and the AMO and NAO (originating in the Atlantic). Over the Holocene, other forcings also come into play that might be expected to show regionally varying responses. By drawing together palaeoclimatic data from a wide range of sites and proxies, the spatial patterns of change over Mesoamerica during the Holocene can be explored and the changing role of different forcings considered. Over the last 4000 years, ENSO-type variability appears to have become increasingly important as summer insolation forcing declined in the northern hemisphere. Differential regional sensitivities to climatic variability, including seasonality, need to be considered, although
resolving the latter is beyond the scope of most of our palaeoenvironmental proxies. Any exploration of
the links between climate change and archaeology needs to take into account the complexity and
inadequacies of our palaeoclimatic understanding based on both data and models.

[317] Range Creek Field Station: The Advantage of “Place”
For archaeologists with strong quantitative and ecological orientations, field stations provide the
opportunity for the long-term study of the past in a defined place. The Range Creek Field Station is one
such place. It is a 3,000 acre field station in the heart of about 50,000 acres of very remote public lands
in central Utah and is managed by the Natural History Museum of Utah at the University of Utah. This
area is rich in well preserved archaeological sites related to the Fremont Complex. It also provides
ongoing opportunities to collect data on the character of variation in modern fauna, flora, geomorphology,
geology, hydrology and weather that contribute to the dynamic environmental landscape of the canyon
today. It provides ongoing opportunities to study palaeoenvironmental proxy data to recast the modern
data into reconstructions of past environments. And it allows for modern experimental studies of the
costs and benefits of a variety of activities to inform anthropologists about how we might expect people
to have adapted to those dynamic environments in the past. We review the status of our current efforts
in this multi-year, multi-disciplinary research project.

Metz, Brent (University of Kansas)

[161] An Ethnographic Approach to Exploring Indigenous Heritage and Identity in the Former Ch’orti’-
Speaking Area
From 2004-2011 the author, who had lived among Ch’orti’-speakers for two years in eastern Guatemala,
expanded his research to historical and embodied indigenous memory in the largest conceivable
extension of the former Ch’orti’-speaking region of Guatemala, Honduras, and El Salvador. He visited the
most remote areas of 31 municipios, videorecording interviews with elders and others said to know the
most about local history and tradition. Nearly all acquaintances were interested in indigenous heritage,
although many did not recognize it in themselves. Certain distinguishing features came into focus as
indicative of ethnic ancestry, but the larger lessons learned include: a) much folklore in the region,
ingenous, Ch’orti’, nor not, is based in Nahua traditions, b) culture and identity are often incongruous, c)
it is difficult to distinguish Ch’orti’, Lenca, and Nahua-Pipil heritage, d) indigeneity today is less about
unadulterated continuities from the ancient past than creative cultural trajectories distinct from those of
dominant populations, and e) a divide between urban and rural cultures and identities matches
considerably with the Ladino/indigenous ethnic split. Something for certain is that more archeological,
historical, and ethnohistorical research is needed to reveal the ancestry of today’s population.

[240] Mars and Venus in retrograde? An analysis of gender patterns in the stories we tell about the
past
It has been observed that, while the number and variety of their practitioners may be expanding, the
overall practice and content of engendered archaeologies seem to have grown static in recent years. We
continue to have similar conversations in session after session, meeting after meeting. At the same time,
another critique of engendered archaeologies holds that our interpretations are peopled with individuals
too like modern subjects, performing modern (Western) gender roles. In a pair of 2010 presentations, I
considered why this might be the case. I concluded that our material-gender relationships with non-
human things in the present (relations that each of us has developed since birth) interfere as we try to
understand the material culture of the past. At the time, I took the critique of how we gender subjects at
face value. In this paper, I present a qualitative analysis of a corpus of recent scholarship in feminist and
gender archaeologies. My goal is to demonstrate the variety (or lack thereof) in our casting of gender
roles in the cultures that we study. Challenging the patterns that have crept into our engendered
narratives of the past might provide an escape from the “holding pattern” in which we find ourselves.

[111] The Early Years of St. Louis: Evidence Gathered at the Madam Haycraft (23SL2334) and Louis Beaudoin (23SL2369) Sites

In 2013, the Missouri Department of Transportation conducted a geophysical survey followed by ten weeks of excavation in an effort to identify and evaluate archaeological deposits prior to proposed reconstruction of the I-64/I-70 interchange with I-55 at the end of the Poplar Street Bridge in downtown St. Louis. The project, located immediately south of the Jefferson National Expansion Memorial and the Gateway Arch, is situated on the southern edge of what was historically the old French village of St. Louis. Excavation not only identified features associated with the mid-nineteenth century occupation of the area, but also remnants of one of the original French homes built in the 1770s. Results of the 2013 field season indicate that portions of two sites, the Madam Haycraft Site and the Louis Beaudoin Site, contain stratified cultural deposits that include an horizon with intact remains dating to the French founding of the city. The discovery of the house owned by Louis Beaudoin, as well as associated features, provides hope that more evidence of the old French village remains to be found.

Meyers, Katy (Michigan State University)

[36] Linking the Spaces of Resting Places: GIS, Anglo-Saxon Archaeology and Linked Open Data

Placing the dead in space, both within the broader landscape and in relationship to one another, has important cultural and social implications. Spatial placement can denote broader social status, aspirational goals of the individual and mourners, religious or ancestral beliefs, or may be indicative of the community’s relationship to the deceased. The importance of space within mortuary archaeology has been recognized for the past half century, and geographic information systems (GIS) has become an integral part of contemporary mortuary research projects. Despite this, primary spatial data from GIS are rarely shared, published, or stored in shareable formats, which inhibits the growth of mortuary spatial studies by forcing constant re-creation of spatial data. Linked open data (LOD) provides a much needed approach for archaeological studies of the deceased. Access and standardization would decrease redundancies, sharing would improve sample size, and linking would allow for creation of more efficient connections between data sets. However, there are numerous challenges of sharing spatial LOD from mortuary sites that need to be addressed. Using Anglo-Saxon burial practices as a case study, I argue that mortuary archaeology and spatial analysis of cemeteries would benefit greatly from the implementation of a LOD plan.

[74] C.G. Holland: Archaeological Survey in a Cultural Crossroads

An important post-World War II archaeologist in Virginia, C.G. Holland is best known for his work on projectile point typology for Virginia and his survey of southwestern Virginia. He was also a long-time editor of the Archaeological Society of Virginia Quarterly Bulletin, and worked on many other sites across the state. This paper reviews his archaeological career, and focuses on important sites, including the Trigg site and the Carter Robinson Mound site, which he identified in his southwestern Virginia survey. In addition, it highlights more recent work on these sites, and assess Holland’s theory of southwestern Virginia as a cultural crossroads in light of these more recent studies.

Meyers, Allan

[330] Pre-Revolutionary Henequen Landscapes of Northwestern Yucatan

The countryside of northwestern Yucatan was transformed during the late nineteenth century in response to the international demand for henequen, a native agave yielding fiber for the cordage industry. Drawing on the bonded labor of Maya-descent and immigrant populations, landowning elites developed an infrastructure of haciendas, railways, and ports that steadily expanded until the Mexican Revolution irrevocably changed the terms under which the henequen export economy operated. The reordering of rural settlements during this Henequen Episode (1860-1915) has strongly influenced the human geography of modern Yucatan, and scholarly interest in the material basis of haciendas and related sites is accelerating. Recent research highlights multiscalar explorations into a variety of historical landscapes that, while enabling the propagation of an agricultural commodity, served as forums for human-
environment interaction, cultural heterogeneity, and class conflict. Case examples shed light on the material conditions that shaped the experiences of rural laborers in the run-up to revolution. Moreover, these studies underscore the prospects and challenges of spatial frameworks for investigating the social dynamics of the henequen boom in Yucatan.

[143]  Understanding Violence: Ritual, Conflict, and Sacrifice in the Basin of Mexico

This paper presents results from recent archaeological excavations of a site of mass human sacrifice in the northern Basin of Mexico. During a time of demographic change and political transformation, a small spot where a series of freshwater springs fed a brackish lagoon became the site of ritual violence. Excavations in 2007 and in 2012 uncovered the decapitated crania of over 180 individuals—more than the estimated populations of villages during this time. Lines and mounds of human skulls, most with articulated cervical vertebrae, constitute the assemblage of human remains. Finger bones, some recovered from eye sockets and cranial cavities, are the only other major represented sub-cranial remains. These characteristics suggest sacrificial offerings but also illustrate the detailed ways in which violence was integrated ritual practice. Furthermore, although taphonomic and depositional processes have affected the site, our analysis suggests that all the victims were male adults, possibly from different social classes and biological populations. Patterns in these data elucidate past rituals, conflicts, and specific historical events. They also force us to question our biases and assumptions about male violence, offering a unique opportunity to carefully interrogate our understandings of past gender relations.

[209]  Assessing Late Pleistocene Hunter-gatherer Mobility in SE Asia through Lithic Technology

Terminal Pleistocene hunter-gatherers of tropical SE Asia employed mixed-subsistence economies that articulated with philopatric mobility to counter resource scarcity in those environments. The peculiar constraints this may have imposed on their mobility suggests that their land-use strategies may have significantly differed from those of contemporary population in Western Eurasia. Stone tool technologies across the region are unspecialized, a reflection of both locally available workable stone and the abundance of organic tool-making materials. This limits what can be inferred about forager mobility on techno-typological grounds. Here, we use an alternative approach focusing on whole assemblages to see whether SE Asian forager land-use strategies fall along a curated-expedient axis documented in other parts of the world at that time. Data from 42 assemblages conform to the expected negative relationship between retouch frequency and artifact density, indicating that, in spite of tropical SE Asia’s ecological distinctiveness, Pleistocene foragers in that region alternated between residential and logistical land-use strategies. Additionally, these data provide a baseline against which to assess the mobility strategies of the Liang Bua hominins, which display a distinctive form of organization that is at odds with that documented throughout the region, with implications for the taxonomy of Homo floresiensis.

Michael, Amy (Michigan State University)

[303]  Exploring the Relationship between Sampling Loci and Developmental Age in Isotopic Studies of Human Teeth: A Pilot Study from Kamenica, Albania

Strontium isotope signatures in human teeth are widely employed to explore human migration through time and across space. This study utilizes technical principles outlined in previous studies, but further explores the methodological practice of strontium isotope research as it relates to sampling location on the enamel surface. Due to discrepancies in results from a preliminary study carried out by one of the authors, we hypothesize here that different isotopic signatures may be exhibited over the extent of the enamel surface on a single tooth, as a function of age. If our hypothesis is supported, this study begins to address possible limitations to strontium research, specifically the subject of multiple movements (Price et al. 2002) and appropriate sampling protocol. First, second, and third molars from two Albanian Iron Age (ca. 3000 BC) individuals were sectioned into thirds and enamel from each section was submitted for strontium isotope analysis at MIT’s Laboratory of Earth, Atmospheric and Planetary Sciences. The
sections sampled correspond with known developmental ages (Reid and Dean 2006), a powerful source of data for bioarchaeologists concerned with sociocultural aspects of prehistoric migration. We present results of the analysis and discuss implications for further research in central and northern Albania.

Traces of Trowels: Assembling Oral Histories of Excavations in the Middle East

Much has been written about the problem of grey literature-- or worse, excavations that have never been published. But even when excavations are published, the perspectives presented are extremely partial. They generally do not include accounts, analysis, or interpretations from hired workers. Often, these workers have worked on many excavations, and have special expertise regarding local archaeological materials that goes unrecorded because of the conditions of documentation in archaeology. I have been conducting ethnographic research at two sites-- Petra in Jordan and Catalhoyuk in Turkey-- in order to assemble oral histories of the longterm excavations at these two places. I have been identifying the men and women hired to work at these sites, and recording their memories of their work and the projects-- along with the stories still circulating in the wider community. Through this research, I will compare the oral histories of these excavations with the conventionally recorded archival data about them, and will make some generalizations about the impact archaeologists have on the communities they work with. How are archaeological projects remembered, and why are they remembered this way? These questions are significant for understanding archaeological as a research endeavor, a social sphere, and an economic practice.

Satellite Paleoecology in Oaxaca, Mexico: Assessing Potential Productivity of the Prehispanic Landscape

Hyperspectral Satellite Imagery (HSI) from the Hyperion Imaging Spectrometer aboard the Earth Observing One satellite has proven to be a powerful tool for the rapid analysis and assessment of large areas. The richness of hyperspectral data (~240 spectral channels) allows fine-grained distinctions between different classes of materials and material states that are indistinguishable to the naked eye. Applications include the analysis of landscape diversity, the identification of specific plant communities and land uses in contemporary landscapes, assessment of urban sprawl and it’s impact on cultural resources, and so on. In this example, we measure the difference in vegetation between dry- and wet-season land cover in Oaxaca, Mexico in order to assess the potential productivity of the landscape in prehispanic times. The Normalized Difference Water Index (NDWI) measures water in plant tissue. Comparison between scenes captured in the wet- and dry-season respectively allows us to assess both the extent of land which can be utilized for rainfall agriculture and the extent of land which can be cultivated year-round. Measures of prehispanic agricultural productivity can then be applied and the potential agricultural yield of the landscape calculated. These measures can be undertaken rapidly, over large areas and over multiple seasons.

Middleton, Abigail (University of Missouri)

Water Management and Agricultural Risk Mitigation in Southwest Coastal Ecuador

This paper discusses recent survey of previously unstudied areas of the El Azucar and Zapotal River valleys in southwest Ecuador. It focuses on the ways in which agricultural communities from the pre-Columbian Late Formative period to the present used water management in agricultural production in high-risk and unstable environments of the littoral region. Previous studies have shown that water management is linked to periods of agricultural expansion and contraction. The paper explores the use of
water management features, known as albarradas, as one strategy in a possible suite of agricultural risk management approaches beginning in the Late Formative-Engoroy period and continuing through the present. Documented agricultural booms and busts and these survey results draw attention to: the lack of paleoenvironmental research in which to ground the study of Late Formative adaptation, the development of agricultural communities in the Late Formative, and adaptations to high risk littoral regions. These new data and possible explanations are presented.

Mihok, Lorena (University of South Florida) and E. Christian Wells (University of South Florida) [190] The Royalization of Northern Honduras, 1502-1788: Trajectories of the Pech, Miskitu, and Tolupan
The processes that Spain and England deployed to engender the loyalty of indigenous groups in southern Mesoamerica to their burgeoning empires resulted in significantly different sociopolitical and economic trajectories for today's populations. Drawing from archaeological and historical research over the past decade, including our own investigations of Pech and English/Miskitu settlements on Roatan Island, we analyze macro- and microdemographic trends in northern Honduras from 1502 to 1788. We argue that the different processes of royalization early in the colonial histories of indigenous groups have significant consequences for descendant populations, including issues pertaining to political access and economic development, among others.

Milbrath, Susan (Florida Museum of Natural History), Debra Walker and Ron Bishop [123] Workshops for Postclassic Effigy Censers in the Chetumal Bay area
Stylistic analysis and neutron activation analysis indicates that effigy censers from Santa Rita, Champoton, and Mayapan are separate traditions. Censers from Chetumal Bay and coastal Campeche are clearly different workshops from Mayapan (Chen Mul Modeled type). Censers from Cerros are stylistically similar to the Kol Modeled type at Santa Rita, a resemblance confirmed by neutron activation studies. Indeed, censer fragments from Santa Rita, Cerros and Colha constitute a single compositional group that is distinct from other Maya pottery. Both stylistic traits and clay sources confirm a localized workshop, probably centered at Santa Rita, the largest Postclassic site in the area.

Milideo, Lauren (Penn State University Department of Geosciences) and Russell Graham (Penn State University Department of Geosciences) [208] Wolf Dens as Pseudo-Sites: Identifying the Influence of Wolves on Bone Assemblages
The scattered bones of carnivore dens, including those of wolves, may superficially mimic archaeological sites, particularly if only a portion of the bone scatter is excavated; it is therefore useful to establish modern taphonomic models to which possible zooarchaeological assemblages may be compared. An analysis of a bone assemblage, consisting almost exclusively of caribou bone, from a modern wolf den in Nunavut, Canada, is used as an example. Analyses of the types of elements present, bone weathering patterns, and the taphonomic markings on the bones, reflecting carnivore processing, were included; we also present spatial analyses of the bone scatter itself. Bones were mapped in place before collection, similar to elements plotted in an archaeological excavation. By examining taphonomic data in conjunction with spatial patterning, we gain new insight into the nature of these sites, and how they differ from archaeological contexts. Toothmarks and fractures are common, and diverse weathering stages are present, indicating extended or repeated occupation; the bones' distribution over a large area is also distinctive. We identify taphonomic and spatial indicators of this assemblage's origin as a wolf den, and suggest potential means of distinguishing such assemblages from those of archaeological origin.

Miljour, Heather (Statistical Research, Inc.) [210] Archaic Period Subsistence and Resource Use in a lower-Bajada Environment
Recent excavations for the Luke Solar Project in the western Phoenix Basin revealed one of the largest Archaic sites known to date, situated on a lower-bajada environment. The Middle and Late Archaic Periods were a time of transition in southern Arizona, as foragers became farmers, ceramics were adopted, and other aspects of life changed. Over the last few decades, new data on the Late Archaic/Early Agricultural period has increased our knowledge of this time period, particularly in riparian areas, but the Middle Archaic is still poorly understood. Middle Archaic sites are scarce and are often small, consisting largely of flaked and ground stone artifacts, faunal collections tend to be scanty if
present, and floral remains only infrequently recovered. The Middle and Late Archaic occupations uncovered as part of the Luke Solar project include thousands of features, a large faunal collection, numerous identifiable plant remains, and a high frequency of ground stone tools. The Luke Solar project provides an excellent opportunity to examine the ways in which Archaic groups interacted with their environment, the available resources, and the subsistence practices of Middle and Late Archaic groups in a lower-bajada environment.

Miller, Virginia (University of Illinois at Chicago)
[25] The Representation of Hair in the Art of Chichén Itzá
For Mesoamerican peoples, human hair was considered to be a receptacle for power, and its treatment a marker of gender, status, and social role. Usually depicted as neatly cut or tightly bound and often covered by an elaborate headdress, in Maya imagery loose or tangled hair signals loss of control, whether through emotional release, intoxication, or death. The reliefs and murals of Chichén Itzá, crowded with multiple human figures, provide a particularly rich environment for the study of costume, adornment, body decoration, and hair. A wide variety of hairstyles is represented here, including carefully-groomed long and short styles typical of the Terminal Classic, “mohawks”, pony-tails, and occasionally completely disheveled hair. Unique to the site are figures sporting very long blond hair, studded with jade beads. This paper will examine the varied treatments of hair at Chichén Itzá within the context of Late and Terminal Classic conventions, with particular attention to captives and others whose hair is displayed with minimal or no head covering, in order to establish how hairstyles expressed identity and status.

Miller, Melanie (University of California, Berkeley), Sabrina Agarwal (University of California, Berkeley) and Carl Langebaek Rueda (Universidad de los Andes, Colombia)
[103] Tracing Dietary Histories through Stable Isotope Analysis: A Case Study from the Muisca of Colombia, 1200-1550 A.D.
The ancient Muisca culture of the Colombian Andes provide a unique opportunity to study human health and diet during an important period of agricultural subsistence and early period of Spanish contact. Stable isotope analysis of human teeth and bone were analyzed from the Muisca archaeological sample from Tibanica, in the Sabana de Bogotá, Colombia (1200 A.D. – 1550 A.D.). Both collagen and apatite were analyzed from both tissues for carbon, nitrogen, and oxygen stable isotopes to provide a robust analysis of the dietary components of both childhood and adult diet. Dietary continuity or change from different periods of childhood to adulthood may be linked to complex social relationships that vary over the lifetime and may be linked to age, sex/gender, and social status. In a complex culture such as the Muisca, food may offer important insights into changing social roles.

Miller, D. Shane (University of Arizona) and Stephen Carmody (University of Tennessee)
[132] The Ideal Free Distribution and the Early Holocene Expansion in the Lower Mid-South
The Clovis culture likely represents an early, widespread colonization episode at the end of the Pleistocene. However, parts of North America were not intensively occupied until well after the disappearance of the Clovis culture. Here, we use a sample of published site distribution and frequency studies in conjunction with the Ideal Free Distribution from Behavioral Ecology to argue that parts of the Cumberland Plateau and Appalachian Summit did not have a sustained human presence until the latter parts of the Younger Dryas and the Early Holocene. This pattern is consistent with a global trend of delayed colonization of highland regions.

[152] Co-Creation and the Cemetery Resource Protection Training (CRPT) Program across Florida
The Cemetery Resource Protection Training (CRPT) program offered by the Florida Public Archaeology Network (FPAN) began in 2011 as a reaction to the rapid deterioration of historic cemeteries in Florida.
During the first year the Northeast Regional Center of FPAN collaborated with community partners to conduct CRPT workshops in each of its seven counties. CRPT has now expanded to over 20 cities across the state. Workshop participants learn to view cemeteries as outdoor museums in their community through morning and afternoon sessions. The morning session focuses on: cemeteries as archaeological sites, laws that protect cemeteries as well as the people who care for cemeteries, the importance of survey and recording, and examples of cemetery projects within the community. The second session puts theory to practice with hands-on landscape assessment, headstone cleaning, and recording in a local cemetery. This paper will assess CRPT as a co-creative public archaeology program and discuss its relevance to the participating communities.

Miller, Kevin and Kenneth Lawrence (SWCA Environmental Consultants)  
[165] To Drill or Not to Drill: Investigations at the Turkey Terrace Site (41FR70), Frio County, Texas
The Turkey Terrace site (41FR70) is a prehistoric open campsite and procurement area situated along the Todos Santos Creek in Frio County, southwestern Texas. Positioned on an alluvial terrace, between the creek and gravel uplands, Turkey Terrace is composed of broadly dispersed surficial artifacts and substantial subsurface cultural deposits associated with Middle–Transitional Archaic to Late Prehistoric occupations. The site's large size and potential importance posed challenges for an associated pipeline project, where directional drilling to avoid sites was the modus operandi. Significance testing served as an effective tool to both narrow the area requiring avoidance drilling and provide important information on the site and prehistory of the area. Unique findings from the testing included stratified cultural deposits within a remnant creek channel and thermal features composed of clay balls. This paper discusses the results of these investigations and the analyses performed, and, in particular, reviews the collaboration between archaeologists and clients in finding a project solution that was beneficial to all.

Miller, Naomi (Univ of Pennsylvania Museum-ISAWS)  
[250] The Ethnobiology of the Warka Vase (Mesopotamia)
Ethnobiological study of antiquity is usually constrained by the limitations of the archaeological remains of plants and animals. Sometimes, ongoing tradition, images, and texts add a symbolic dimension. Such a study has been done of the Warka Vase, an iconic artifact of Mesopotamia. The lowest of three registers appears to represent the basis of Mesopotamian life: water, plants, and animals. Identification of the water and animals is relatively straightforward. In the absence of serious botanical study, the plants depicted are usually thought to be grain and flax. Analysis of the plant imagery in concert with that of archaic signs, botanical characteristics, and our understanding of Mesopotamian agriculture and tradition shows that the 'grain' is date palm and confirms the other plant as flax.

Miller, Katherine (Arizona State University)  
[291] Creating Community at Copan: The Intersection of Kinship and Migration at the Maya Frontier
The role of kinship in social organization can be explored within the nexus of a social group, the residential unit, through a careful analysis of archaeologically contextualized human remains thus highlighting the internal structure of ancient societies. The neighborhoods that surround the core of Copan, a major sociopolitical center nestled at the southeastern frontier of the Maya region and western edge of culturally diverse central Honduras, serve as an ideal case to explore the construction of community within an ancient city. This paper considers two competing theoretical models of ancient Maya social organization (House vs. Lineage) and considers multiple possibilities of fictive and biological kinship, short or long-term co-residence, and long-distance kin affiliation in a densely populated dynamic urban environment. The Copan human skeletal collection, the largest in Mesoamerica, provides an ideal context for exploring the lives of Late Classic (AD 600-820) Copanecos. New biogeochemical and biodistance data, drawn from those who directly participated in the creation and maintenance of social organization and were subsequently interred at Copan, provide insight into the complex relationships of Copan's inhabitants to each other, to their neighbors, and beyond.

Miller, Myles (GMI) and Roger Anyon (Pima County Cultural Resources and Historic Preser)  
[333] Burning, Ritual, and Communal Architecture Transformation as Markers of Social Change
Burning domestic and communal structures as a means of ritual retirement and transformation from structures to ancestral landscape markers is documented throughout the prehispanic Southwest. In this paper, we examine two temporally distinct episodes of communal architecture burnings in southern New Mexico: great kivas in Mimbres Mogollon pithouse villages during the mid AD 900s and communal
rooms in Jornada pueblos during the AD 1300s. Both involved dramatic and public ritual events that marked social change. In the case of Mimbres great kivas the succeeding social transformations occurred in situ; the population continued to live at the same place on the landscape and burned kivas became important ritual spaces within the village. For Jornada pueblos, in contrast, the succeeding social transformations occurred elsewhere and communal rooms became important places in a much larger cultural landscape. We evaluate these transformational episodes with respect to the complex continuum of societal disintegration and integration.

Miller, G. Logan (Ohio State University)

Variation in the Organization of Ritually Motivated Production at Ohio Hopewell Earthworks

In this presentation, I examine the organization of production at monumental earthworks through the lens of ritual economy. Specifically, I examine the production of socially-valued goods at two Ohio Hopewell earthworks (Fort Ancient and Stubbs) by studying the function of stone bladelets through microwear analysis. Previous research demonstrated that bladelets were important elements in the production of socially-valued goods by inhabitants of Fort Ancient. However, Fort Ancient is often cited as an anomaly among Hopewell earthworks. I will compare and contrast microwear and other contextual evidence from Fort Ancient and Stubbs in order to understand variation in the organization of production. Ultimately, I will present evidence that, despite the lack of a centralized political hierarchy, Hopewell craft production was a complex, multi-faceted process largely organized by the social/ceremonial gatherings at these earthworks.

Miller-Sisson, Misha (University of California San Diego) and Beniamino Volta (University of California San Diego)

Changes in Sub-royal Elite Culture at the Maya Site of Uxul: Before and After the Incursion of the Kaan Polity

Archaeological models for ancient Maya political organization oscillate between highly centralized regional “superstates” and weakly integrated segmentary polities. Epigraphic evidence suggests that, during the Late Classic period (A.D. 600 – 900), the Kaan dynasty of Calakmul controlled one of the largest and most powerful regional states of the central Maya lowlands. The site of Uxul, Campeche, Mexico, has been proposed as a secondary center within this regional hierarchy. This talk presents preliminary research on the effects of the integration of Uxul within the Kaan state. Specifically, we examine evidence for the presence and social function of sub-royal elite groups at the site. Extensive mapping by members of the Uxul Project has defined a site core with a royal palace and large public architecture. We have also identified a number of possible elite household groups of varying degrees of size and complexity outside of the central area of the site. Excavations in some of these groups, combined with comparative settlement pattern analysis, allow us to make some preliminary observations on the changing nature and political role of sub-royal elites at Uxul throughout the site’s history.

Millhauser, John (North Carolina State University) and Christopher Morehart (Arizona State University)

Hiding in Plain Sight: The Significance of Small Sites in the Northern Basin of Mexico

Conducting fieldwork away from large settlements enhances our reconstructions of the past and our theory building. Simultaneously, locating small sites that are well-preserved, collecting data from a representative sample, and confronting the mindset of “if you’ve seen one you’ve seen them all” are persistent challenges. In this paper, we present ongoing research from the northern Basin of Mexico’s lake zone that documents small sites’ historical significance during times of demographic growth and political economic change. Our examples target different kinds of small sites—settlements, work areas, and places of worship located beyond the boundaries of cities, towns, and villages. These cases demonstrate that the smallest and seemingly least significant sites were key places of social reproduction and transformation. In this region, as with others, many of these places are rapidly being destroyed by population growth and infrastructural development, reinforcing the urgency to invest serious research in them. Their documentation and intensive study enriches our understandings of multiple dimensions of past settlements, landscapes, economies, and sociopolitical systems, offering a unique vantage from which to contribute to existing models of central Mexico’s past.
Facial Expression among The Moche

Phases III and IV of the Moche culture in the Northern coast of Peru developed ceramic vessels with realistic portrait heads that were quite distinct among all other head representation in the Andean world. Despite the generic denomination of "portrait" these vessels offer a great variety of anthropomorphic motives. I am interested in those representations of human faces that would allow one to establish facial expressions using the Facial Action Coding System and to explore the relationship between emotions and power in time and spatial contexts during the period of Moche expansion.

Patterns of Structure: The Fiber Artifacts of La Tiza

La Tiza is an ancient Andean site located close to the modern town of Nasca along the southern coast of Peru. Hundreds of fiber artifact specimens (including yarns, cords, knots, braids, and woven textiles) have been recovered from contexts from the Archaic through to the Late Intermediate Period and possibly Late Horizon. The majority of the textiles have Middle Horizon (A.D. 650 – 1000) and Late Intermediate Period (A.D. 1000 – 1476) associations, and come from both domestic and mortuary contexts. This study analyzed the fiber content (mostly cotton and wool, but human hair and other vegetal fibers were observed), structure, and decoration from a sample of those fiber artifact specimens. This data was compared to similar studies of Andean fiber craft and the identified patterns utilized in a discussion of technology, identity and cultural affiliation. To the ancient Andean people, the characteristics of fiber artifacts, even those that seem more utilitarian, were likely of greater importance in the communication of identity and affiliation than those of us from the industrialized world are accustomed to.

Cuisines as Networks of Situated Practice in Scalar Perspective

The “communities of practice” concept has been effectively used to understand the transmission of technological practices during production. In this paper I do two things. First, I argue that another fruitful way of looking at communities of practice is through consumption. For ceramics, these patterns of consumption revolve around cuisines as situated practices: the choices that people made in how and what food was prepared, the containers they were served in, and to whom. Second, I look at how these container choices by communities of consumption accumulated at large temporal and spatial scales to produce distinctive regional networks of practices. I draw on research by the Southwest Social Networks Project on late prehispanic period ceramics from the western Southwest to show how networks were produced through the accumulation of choices within communities of consumption. Such a relational perspective requires that we consider networks that are built on shared ideologies and identities in and through consumption, especially those taking place in the most visible and power laden settings. Decorated ceramics, especially polychromes, were one medium through which different communities were constructed. The growth and dissipation of these networks reveals social relations that spanned generations and regions during this dynamic period.

Novice Flint Knapping, Seasonal Mobility, and Palaeo-Eskimo Lithic Raw Material Acquisition in the Interior of Southern Baffin Island, Nunavut, Canada

The identification of novice skill in the archaeological record has been used successfully to infer the presence of children when examining certain technological mediums. However, among lithic toolmakers, replicative experiments demonstrate that to successfully knap stone one needs sufficient upper body strength and hand-eye coordination, which arguably develop later in adolescence meaning that the identification of novice skill among lithics may not directly reflect the presence of children per se. On southern Baffin Island, several early Palaeo-Eskimo sites located in the deep interior exhibit evidence of novice skill suggesting that physical endurance may have been another criterion needed to become an
apprentice in this region. Novice reduction episodes are consumptive of raw material and on southern Baffin Island, chert is abundant in the interior yet restricted on the coast; therefore, it makes sense that novices would travel long distances to the interior to learn to break rocks. In 2013, we identified two toolstone source areas in the interior that further exhibit evidence of novice skill. In this paper, we describe these sites and speculate on the pivotal role they played in enculturating Palaeo-Eskimo flintknappers through long-distance seasonal travels between southern Baffin Island’s inland and coastal areas.

Minc, Leah

[329] Trace-Element Analyses of Near Eastern Ceramics: Overview and Introduction
In spite of the critical insights which chemical analyses can provide for studies of inter-regional exchange, relatively few characterization studies have been carried out on Near Eastern ceramics, and these represent a limited number of ceramic wares, sites, and chronological periods. To address this sparsity, the OSU Archaeometry Lab initiated a series of collaborative studies aimed at rapidly building-up a comparative data base of ceramic pastes for the Near East. Our goals were to dramatically expand the spatial scope of ceramic trace-element data for the region to include major sites and culture areas, and to begin using these data to directly address models of regional economic organization and inter-regional interaction. With the support of NSF and participating museums, we have now completed trace-element analyses of nearly 1700 ceramic samples, from key sites stretching across Syria, Iraq, and Iran. These analyses provide physical evidence allowing researchers to monitor whether ceramic vessels and containers were moving between the lowlands of greater Mesopotamia and the surrounding highlands, and to reexamine the significance of the shared ceramic styles marking the “Uruk Expansion”. This paper presents an overview of significant past ceramic characterization studies and introduces the collaborative projects presented in this session.

[268] Down the River without a Shovel: Investigating the Usefulness of Archaeogeophysical Survey along the Colorado River through the Grand Canyon
The terraces and deltas along the Colorado River through the Grand Canyon National Park contain hundreds of archaeological sites. Because access to most of these sites is restricted to rafts, through some of the most challenging whitewater in the world, it is one of the most demanding locations for conducting fieldwork in the continental United States. This paper presents the results of a cooperative project between the National Park Service and University of Kentucky, designed to evaluate the usefulness of geophysical survey in this rugged terrain. In addition to access, other challenges had to be overcome, including limiting disturbance to the archaeological sites and vegetation, protecting and maintaining the geophysical equipment in a wilderness environment, and the logistical coordination of a 226-mile one-way trip down the river. In the end, with some modifications to our typical field methodologies, geophysical techniques proved to be an effective tool for managing archaeological resources along the River. Park Service cultural resource managers now have a new set of tools to help them manage these heritage resources.

[322] Something Old, Something New: Integrating Legacy Data and Preparing for the Open Access Future
Long-term archaeological research projects generate vast amounts of heterogeneous data recorded over the years by teams with differing and evolving recording standards and methodologies. This legacy data can be difficult to integrate with newer excavation datasets, incomprehensible to outside researchers, and incompatible with modern technologies, such as GIS and relational databases. At Ancient Egypt Research Associates, we have twenty-five years of data from our own excavations at three large Old
Kingdom sites in Giza, Egypt - the settlement of Heit el-Ghurab, Khentkawes Town, and the Menkaure Valley Temple - as well as the published excavation data from archaeologists George Reisner’s and Selim Hassan’s previous work in the area. We have undertaken a “Data Curation Project” to reassess, standardize and fully digitize all of our excavation data so that it will be internally consistent, compatible with modern recording techniques and technologies, integrated into our GIS, and, ultimately, online, open access, and available to the public. This is a long process but has already resulted in a more complete dataset that will enable both current team members and outside researchers to better utilize and contextualize the entirety of the work done on our sites.

Mires, Ann Marie

[283] Standing the Test of Time: Forensic Archaeology on Trial

Forensic Anthropologists assist in the recovery of skeletalized remains from crime scenes, profile human remains, assess the circumstances of death, and evaluate traumatic injury. The analyst documents cases without knowing whether they will be prosecuted in the legal system. The work must stand in perpetuity, until the case proceeds to trial. The analyst is bound to the duties and responsibilities of an expert witness. In 2000, four graves containing six individuals were exhumed in Massachusetts. As the Forensic Anthropologist at the OCME, I directed the excavations and analysis of the material. Standard archaeological procedures were implemented to locate and excavate the graves, which had been revealed by an informant. At the time of the excavations, the alleged perpetrator of the crimes, Whitey Bulger, had fled. It was not until his eventual capture in 2012, that the prosecution proceeded. In June of 2013, the U.S. Attorney’s office prepared for trial on thirty-two counts including murder, racketeering, and extortion. The exhumations constituted six of the nineteen murders, the bulk of the forensic evidence presented at trial. The archaeological documentation was incumbent with creating the forensic record and was done properly thus allowing the forensic record to stand in perpetuity.

[325] Comparison of Fuelwood Use at Two Dorset Palaeoeskimo Sites in Newfoundland

This paper presents the results from an ongoing analysis of Dorset Palaeoeskimo use of fuelwood from two different forested ecoregions in Newfoundland. The aim is to understand the relationship between tree species available in a region and those selected for fuelwood. The Dorset were largely an arctic people who depended heavily on seal fat for fuel and lived in an environment where wood availability was mainly restricted to driftwood and shrubs. This study will contribute to an understanding of Dorset use of wood as a fuel source in their occupation of a boreal forest environment. The methodology involved the genus identification of 2000 charcoal fragments from the Middle Dorset (2000-1500 BP) sites of Phillip’s Garden (EeBi-01) and Stock Cove (CkAI-3). Phillip’s Garden on the Northern Peninsula is situated in a subarctic climate and is occupied by a forest largely composed of softwoods, whereas Stock Cove on the Isthmus of Avalon is characterized by a more temperate climate and a mixed forest of both softwoods and hardwoods. A comparison of fuelwood use at these two sites will reveal preferences where multiple species were readily available and thus contribute to an understanding of Dorset practices associated with wood use.

Mitchell, Spencer (Humboldt State University)

[140] Experimental Observations and Archaeological Implications: The Ancient Maya Codex Manufacturing Process

Experimental archaeology has an important role to play in our understanding of the formation processes in the archaeological record. For the scope of this research, experimental archaeology enables targeted examination of codex manufacturing by the ancient Maya. Although the majority of surviving written material is found on ceramics, monuments, and altars, it is believed that the ancient Maya primarily documented their information on codices made from fig-tree bark paper. However, due to adverse environmental conditions in the Maya Lowlands and the devastation caused by Bishop Diego de Landa very little evidence of the codices has survived. This poster details ongoing experimental research focusing on the tools, raw material, and painting techniques utilized by ancient Maya scribes. I replicated
pages twenty-four to twenty-seven of the Dresden Codex. The data in this experiment has revealed that codex production is a long and difficult process, which can leave the individual with lasting physical ailments.

Mitchell, Mark [333] see Ward, Christine

Mixter, Jeffrey (Arkansas Archeological Survey)

Archaeological Evidence for the Hernando de Soto Expedition West of the Mississippi River

After traveling around the Southeast for two years, the Hernando de Soto expedition crossed the Mississippi River in June of 1541. At this point, the expedition was in what is now Arkansas, and traveled in the state for nearly a year until Soto's death in May of 1542. The remaining members of the expedition eventually made their way to Mexico. Archaeological evidence of the expedition is rare west of the Mississippi, largely because they had lost or given away most of the trade goods and other identifiable Spanish material. The best information to date comes from the Parkin site, thought to be the village of Casqui described in the narratives. Finds of halberds and Clarksdale bells provide additional hints of the route, but determining the expedition's pathway after leaving Casqui is frustratingly difficult.

Community Politics Following the Maya Collapse: Preliminary Results from Actuncan, Belize

In contrast to the longstanding focus on the 9th century political and demographic collapse of the southern Maya Lowlands, little attention has focused on the strategies of remnant communities that survived in place in the immediate aftermath of this collapse. In the absence of failed divine kings, groups that remained were forced to negotiate new forms of political authority. These negotiations happened first at the local level, where individual communities freed of the constraints of divine kingship developed varied solutions to fill the power void and legitimate the authority of new leaders. One such community was located at the site of Actuncan in the lower Mopan River Valley of western Belize. The collapse of nearby Xunantunich marks the end of divine kings in the region and follows the general depopulation of the valley. In contrast, the population of Actuncan’s site core remains steady throughout the Terminal Classic period (A.D. 780 to 1000). The re-initiation of political life at the site is marked by the construction of a large public platform placed in the middle of the site’s Classic period core. Here, I report on investigations into the civic and ritual architecture associated with this revival.

Miyar, Kathryn (Southeast Archeological Center, National Park Service)

The Reconstruction of Kin Relations and Cultural Identity at Bull Creek (9ME1)

This study investigates kin relations within the Mississippi Period cemetery of Bull Creek (9ME1). The Bull Creek site is located in Georgia and contains examples of unique southeastern cultural practices including intentional cranial modification and effigy burial objects. The application of bioarchaeological techniques to kinship reconstruction has distinct potential to expound upon concepts of relatedness. However, metric and non-metric data collection from skeletal remains is commonly limited by poor preservation and obscured by the lifestyle and ontogeny of the individual (e.g., dental attrition from masticatory and non-masticatory use). Alternatively, certain biological markers, such as cultural modification to the crania and dentition, can provide information to reconstruct past kinship and social identity when used in conjunction with mortuary and ethnographic data. This research employs a cross-disciplinary approach to assess kinship, cultural affiliation, and social identity frameworks at Bull Creek. Different methodologies and lines of evidence are synthesized to assess relations in this previously unidentifiable cultural group, including-geometric morphometric shape analysis of crania, ethnographic data, demographics, and spatial patterning of variables such as funerary objects, cranial shape, and burial orientation. This research employs techniques that move beyond identification of genetic affiliation to evaluate socially constructed kinship and identity.

Mizoguchi, Koji (Kyushu University, Japan)

How can We Be “Responsible” Archaeologically?
This paper examines how we can be ‘responsible’ in the current archaeological discursive space. How the notion of responsibility is used is examined, and it is revealed that the use increasingly focuses on ‘social responsibility’, which is defined to do things to enhance the well-being of human individuals or communities. It is pointed out that the stakeholders of archaeological data/information include the ‘dead’ who left behind material differences which we study, and they cannot have their say over the way their well-being is enhanced/destroyed. Some of us argue that this ‘voice of the dead’ can be represented by those who do not differentiate themselves from their ancestors in their life-world. However, the other stakeholders live their own life-worlds, and they also have their ways of categorizing and perceiving things. This paper concludes by arguing the following: 1) we can be responsible to one another archaeologically by agreeing that we have to make an effort to create a condition in which we can dispute each other’s rights as smooth as possible; and 2) we have to create a condition in which we can do so on equal terms.

Mock, Cary and Elizabeth Rushton (University of Nottingham) [158]  
**Historical Climate of Belize**

Historical data provide a longer perspective of climate variability well before the temporal coverage of modern instrumental records. These records possess sub-daily temporal resolution, providing a means of independent verification and calibration for other high-resolution paleoclimatic proxy data and assessing human impacts. This study utilizes the best high-quality sub-daily precipitation data from Belize, dating back to the 1820s and being located in a sensitive area concerning the trade winds, winter cold-air outbreaks, and teleconnections such as the El Nino-Southern Oscillation. Data were extracted from numerous United States and UK archives, including meteorological registers, ship logbooks, newspapers, and colonial records. All data were critically evaluated concerning quality. Corrections included dealing with different fixed observation times, various instrumental exposures, and assessing qualitative weather information. Several climate indices, indicative of dryness and precipitation, were formulated to closely reflect societal responses of the mahogany trade. Results indicate generally increased rainfall during the 19th century at decadal time frames during busier activity of the mahogany trade, but extreme years of wetness and drought likely played prominent societal impacts as well. The role of hurricanes and El Nino on extreme years is limited to a few events, such as in 1864 and 1877–1878, respectively.

Moe, Jeanne (Project Archaeology-BLM) [96]  
**Archaeology and the Common Core State Standards: All Hands on Deck**

The Common Core State Standards, scheduled for implementation in the 2014-2015 academic year, provide an unprecedented opportunity to introduce archaeology education in classrooms nationwide. The Common Core calls for inquiry-based instruction, integration of knowledge, cultural understanding and practical cultural literacy, high-level reading in science and social studies, and performance-based assessments. The hallmarks of the Common Core fit well with archaeology education and archaeologists can provide teachers with some of the tools they need to implement the new national standards. Well-designed archaeology education curricula can supply teachers with classroom-ready ways to teach many of the new requirements in science and social studies literacy. This paper will explore the alignment of existing archaeology education materials with the Common Core, the essential role of professional archaeologists in delivering these materials to teachers throughout the nation, and our next steps for better serving teachers, students, and the general public with the results of archaeological research.

**Geophysical and Geomatic Investigations of the Mapoon Mission Cemeteries, North Queensland, Australia**

Two cemeteries associated with the former Mapoon Aboriginal Mission, founded in 1891 and located on western Cape York in North Queensland, were the subject of geophysical and geomatic investigations. These investigations aimed to locate individual graves, identify the presence of coffins or other burial accoutrements and to define the extent of these cemeteries. Ground penetrating radar investigations
located more than 100 unmarked graves across both cemeteries. Magnetometry was unable to resolve graves, but did identify a large amount of subsurface metal, including the remains of a house formerly located within the area of investigation of the larger cemetery. Photogrammetric investigations undertaken allowed for the development of a high-resolution digital elevation model, which enabled topographic correction of the GPR slice maps. These results are important to Mapoon people to look after the remains of their 'old people' and show respect for their ancestry by fencing the larger cemetery, demarcating identified graves and the future construction of a memorial and garden in this important cultural place.

Mohanty, Sudarsana

[146] Engendered Mortuary Rituals: A Study of Gender Identity in Ychma Society

The Ychma site of Panquima in the Lurin Valley of central coastal Peru dates from the 13th to 15th centuries A.D. The site provides an interesting case study for the development of ideologies, including mortuary rituals, due to the close proximity and relationship this Ychma community maintained with the important Andean religious center of Pachacamac. Significantly, the burials recovered were found in the domestic sector indicating a blurring of lines within the organization of the Ychma community, while the contextual information also does not support an interpretation of ancestor worship. By focusing on the form of the graves and their association with domestic structures, it is the goal of this paper to analyze the development of gender identities in the Ychma community as they were manifested in mortuary rituals. More broadly, this analysis engages in a dialogue about the social and political role of men, women and children within Peruvian communities at this time.

[173] Identifying Marine Fish Vertebrae in Archaeological Sites: A Guide Based on Remains from the Northwest Coast of North America

Archaeologists have relied on artifact typologies since the discipline emerged. Established typologies help expedite the analytic process by formalizing rules of assignment and facilitating assemblage comparisons. Zooarchaeological identification, however, does not typically use typologies. As a result, most faunal identifications are based on a set of unspecified rules, which can lead to inter-observer variation in taxonomic assignment. This problem is especially pronounced with regard to marine fish taxa; identification criteria are rarely described in site reports, making comparison to other fish assemblages challenging. In addition, each faunal analyst or lab has to develop their own rules, impeding research progress. To help address these concerns, we developed criteria for identifying marine fish vertebrae based on ongoing work on the Olympic Peninsula, Washington state. Our criteria serve as an aid in distinguishing vertebrae between families of marine fish, as well as within families and genera when appropriate. Our study includes criteria for vertebrae identification within a variety of common marine taxa, including large orders such as Scorpaeniformes (scorpionfishes) and Pleuronectiformes (flatfish). These rules help address the dearth of information on how identifications can be made and will help future analysts by providing formal rules for testing and applying to other fish assemblages.

Molano, Shaina (PIARA) and Rebecca Bria (Vanderbuilt University, PIARA)

[105] Exploring Variation in Cranial Modification at Hualcayán, Ancash highlands, Peru

Sustained excavations between 2011 and 2013 at the archaeological complex of Hualcayán in highland Ancash, Peru have provided a great number of skeletal materials with cranial modification from several tomb types, dating between the Early Intermediate Period and Middle Horizon (1-600 CE). As a cultural practice that preserves in the skeletal record, cranial modification is a form of permanent body alteration that provides a powerful tool for understanding group identity, social structure, and status in a given society. We recovered 53 complete crania and 43 partial crania with modifications from three tomb types at Hualcayán: free standing square chullpa structures, machay structures below boulders, and semi-subterranean tombs. Preliminary analysis of these modified crania show different types of cranial modification including annular, fronto-occipital, frontal, and bi-lobate modification in varying degrees. The distribution of these modified crania across tomb types allows us to question why certain modifications are associated with particular burial types, locations, and periods. Further analysis of these crania will allow us to learn more about the local customs, lineage groups, and social identity of the ancient population of Hualcayán.

Molinar, Marissa Selena (University of Florida)

[90] Drawing the Hunt: Female Agency in the Age of Hunting in the Coso Range
The Middle Archaic period in California is characterized by population growth and movement, resource intensification, technological innovation and a flourishing of artistic traditions. It is also characterized by an increase in large-game hunting, a practice that would seem to contradict general assumptions of subsistence in such a scenario. One model explaining these developments posits that intensification of big-game hunting was not linked to common provisioning, but, rather, it may have been an arena for individual male achievement resulting in cultural elaboration, including the proliferation of bighorn sheep petroglyphs. It has been asserted that women would have participated and benefited from this system, yet the types of female participation have not been investigated. My aim in this paper is to assess this model and to broaden its scope by identifying evidence of female participation, linked particularly to the simultaneous proliferation of patterned-body anthropomorphic petroglyphs in the area. The model's explanatory potential and the extensive body of ethnographic and historical data from the region are uniquely situated for considerations of female agency and practice, a subject of research that is nearly absent in the scholarship of the Coso Range and California Middle Archaic.

Mollenhauer, Jillian (Metropolitan State University of Denver)

[204] Olmec Sculpture and the Aesthetics of Rock Art
The development of freestanding stone sculpture by the Olmec culture of Mesoamerica's Gulf lowlands has long been identified by scholars as one of the defining hallmarks of emerging civilization during the Preclassic period. In this same period outside of the Gulf lowlands, freestanding sculpture appeared and was in some case eclipsed by various forms of rock art. However, the influence of rock art as an artistic practice, which may intersect or overlap with freestanding sculpture, has been almost entirely absent from discussions of Preclassic art in general and Olmec sculpture in particular. Rather, these works are more often integrated into iconographic discussions that ignore or minimize the unique contributions of rock art to the development of Preclassic visual culture. This paper will argue that although Olmec societies were largely forced to develop freestanding sculpture as a response to the geography of the Gulf lowlands, many of these works display elements that may be relatable to the aesthetics and functions of rock art. By reconsidering the current conceptual divide between rock art and sculpture, scholars may attain new insights into the Olmec artistic tradition and the ideological construction of Olmec sites and landscapes.

Moloney, Mike (University of Calgary)

[107] Modelling Shipboard Societies: An Examination of the Applicability of socio-Spatial Modelling to Shipwrecks
The study of shipboard societies relies heavily on the integration of data from a variety of sources (eg. historic records, archaeology, literature, etc.). Each piece of the puzzle is used to inform and re-inform the others in a dialectic, which produces a strong image of life aboard ship. In much the same way computer-based models begin with a set of variables and are slowly calibrated through testing and reinterpretation to produce a working model. The use of computer-based modelling, in archaeology, is often criticized for it's seemingly generalist approach. An unfair critique as models require comparative data that can take years to assemble archaeologically, and therefore only appear to generalize. The modelling of shipboard societies can benefit from hundreds of years of documentation that can help build a strong model before it is ever applied to archaeological sites. This paper examines the benefits of combining computer-based spatial modelling with existing strategies for understanding shipboard culture in an effort to exploit the benefits of computer modelling in the investigation of shipwrecks.

Molton, Jada (Jada Molton)

[175] Lithic Artifact Distributions and Social Organization in Housepit 54, Bridge River Site, British Columbia
The past occupants of the Bridge River pithouse village (EeRi4) located in south-central British Columbia left a remarkable record of stratified occupation floors. Housepit 54, which has been the focus of the latest excavations starting in 2012, contains at least 15 superimposed anthropogenic floors, dating ca.1100-1500 B.P. and during the Fur Trade period. This poster presents an analysis of variation in lithic artifacts to determine whether space on several floors was organized by multifamily domestic activity zones or activity-specific areas. The study explores socio-economic and political changes over time by comparing artifact distributions on multiple floors. This study will lead to an enhanced understanding of residential social organization and the use of space within pithouses in the interior Pacific Northwest.

[266] Late Prehistoric Paleodemographic Trends in the Midcontinent North America Reconstructed through Multiple Proxies from Angel Mounds

Angel Mounds, one of the largest Mississippian towns in the lower Ohio Valley, was established prior to AD 1100, grew in prominence, and was abandoned by AD 1450. Over sixty radiocarbon ages derived from earthworks, palisades, structures, and other features between 1952 and 2013 provide a very detailed chronology of the town’s construction and development. Using this record, Bayesian chronological models tracing changes in the numbers of structures and episodes of palisade and mound construction were developed using OXCAL. The results of these models indicate that Angel Mounds underwent two main developmental phases. The first, ~AD 1100-1300, included significant mound construction and use but few structures and no palisades were built. During the second, AD 1300-1450, the majority of structures and at least three palisades were built. Mounds constructed earlier continued to be used and expanded upon after AD 1300. Based the chronological models, sizes of structures, construction energetics for palisades and earthworks, and the archaeological record, local and regional demography were traced to provide a record of changing population trends within Angel Mounds and the surrounding region. These results are also compared to other estimates of population at European contact.

Moncel, Marie-helene

[26] Emergence of Levallois Core Technology in Southern Europe

Our aim is to investigate the oldest evidence of Levallois core technology in Southern Europe to estimate the age, to describe its technological diversity, relationships with raw materials, location of sites, nature of activities and association with other core technologies and types of tools. Some sites will be chosen to illustrate the discourse in France, Italy and Spain. Their characteristics will be compared with data from Northern Europe and Central Europe sites in order to establish its specificity in this part of Europe in term of technological behavior and age of emergence.

Recognition of establishment phases into Late Acheulean assemblages derives from the way these industries are interpreted by adopting either a stricter or a broader concept. Discussion of the origin will be highlighted by a discussion on the definition and the diverse hypotheses: origin of Levallois technology in Europe and the Near East as an in situ evolution from handaxe technology, existence of continuous or discontinuous contacts among human groups distributed across the Mediterranean during MIS 9 due to higher mobility, other land-use or demographical increase involving exchanges of technological skills and complex social interactions, introduction of prepared-core technologies in Europe from Africa by a dispersal event.

[26] Is There a “Real” Levallois?

An interesting paradox has emerged within recent years. On the one hand, researchers carrying out flintknapping experiments have worked hard to demonstrate that Levallois technology is a superior strategy that reduces waste and produces thinner and more standardized flakes with more cutting edge. The capacity for shaping these cores is argued to require special, advanced cognitive and cultural abilities. Significantly, the basis for these experiments is always an idealized, ‘classic’ model of Levallois technology (“preferential”). On the other hand, researchers working directly with Upper Pleistocene lithic assemblages in Europe and utilizing a predominantly chaîne opératoire approach to describe technology, are documenting increasing varieties of Levallois technology. This raises two questions: 1) How common is classic Levallois technology (of the type modeled in the experiments) in the archaeological record? 2) Do the many Levallois variants fit the experiments’ conclusions regarding economy, standardization, and shape? This paper addresses these questions and explores their implications for our understanding of human cognitive and cultural development during the later Pleistocene.

Monroe, J. Cameron (University of California, Santa Cruz)

[205] Landscapes of Power and Ambivalence in Precolonial Dahomey, West Africa
Archaeologies of social complexity and the state in West Africa have long focused on major urban centers associated with a handful of expansive kingdoms dating to the last millennium. In recent decades, archaeologists have turned to the countryside to provide an alternative view on the nature of urbanism and power relations across regions. This intellectual turn, however, has been bedeviled by the methodological problem of identifying smaller sites, the result of poor site visibility across the region. Recently completed regional analysis initiated on the Abomey Plateau of the Republic of Benin adopted a feature-based approach to regional survey to circumvent this issue. Based on these data, I argue in this paper that rather than being politically insignificant, the "small sites" identified across the countryside were active determinants in driving state political policy in the precolonial Kingdom of Dahomey.

Gathering and Wood Exploitation in Cabeço da Amoreira (Muge shellmiddens): New Methods and Data from Charcoal Analyses

Woodland exploitation and gathering activities are important matters of economic and subsistence organization of past human societies. Cabeço da Amoreira, a Muge Mesolithic site, is located in an appropriate area for exploitation of both estuarine and woodland resources. Wood charcoal analyses have been carried out in Cabeço da Amoreira. Botanical samples taken from different areas of excavation have been processed and over 2800 charcoal fragments have been observed. This paper will present results of this study including the identification of species as well as the range of taphonomic processes occurring during the gathering, processing, and burning of wood. This is essential to understanding the woodland management and resource handling practices within the site by Mesolithic societies of Cabeço da Amoreira.

GIS Modeling for Underwater Paleoindian Age Archaeology Sites in SE Alaska

The coastline of SE Alaska was submerged by post-Pleistocene sea level rise by at least 16,000 cal yrs BP and rose above modern sea level by approximately 10,600 cal yrs BP. The submerged continental shelf was modeled using bathymetry and other data to identify areas exhibiting high potential for the occurrence of archaeological sites (NSF OPP -#0703980 and 1108367). An archaeological settlement model employed ESRI ArcGIS and GRASS to identify survey areas. The iterative model incorporated both inductive and deductive methods. It uses archaeological location data including slope; aspect; distance from stream, lakes, coastlines, and known archaeological sites; and, coastal sinuosity.

The Problems and Potential of Nomadic Archaeology in the American Southwest

The iconic image of the plains nomad has long been a part of American popular culture and academic research. Although the historical presence of plains nomads is well documented in the Southwest, the material traces of these groups have yet to be engaged with systematically. This paucity of archaeological interest can be attributed in part to the rich tradition of Puebloan research in the Southwest and the perceived absence and simplicity of nomadic material culture. Over the past several years, however, archaeological research in New Mexico has revealed the abundance and diversity of nomadic material culture. In this paper, I will use archaeological data from three nomadic sites in northern New Mexico to discuss the potential benefits and problems of using rock art, lithics, and ceramics to date and culturally affiliate mobile sites. Through a discussion of recent research I hope to complement the well-documented historical presence of plains people in New Mexico while highlighting the complexity of nomadic culture and interaction over time.

Moodie, Steven
[302]  Identity, Authority and Social Memory: Excavations at the Ixchel Ballcourt, 2011-2012
This paper presents the Social Archaeology Research Program’s (SARP) excavations of a Middle-Late Classic (AD 650-750) ballcourt at the ancient Maya center of Ixchel, located in the North Vaca Plateau of the Cayo District, Belize. These excavations revealed that the ballcourt was deliberately positioned to use a simple, Terminal Preclassic-Early Classic (AD 100-300) cache to mark the central axis of its playing alley, highlighting that the ballcourt was the latest construction at a multi-generational locus for ritual action. The socio-political role of monumental architecture and caching practices can be explained by recognizing their interdependent and dynamic relationship with ritual performance. This paper explores how the ballcourt and ballgame were used to mediate interactions between the mortal and spiritual realms of ancient Maya ideology, the power relations between rulers and the ruled, and competitions for political dominance between ancient Maya elites.

[261]  Understanding the Social Context of Inuit Ceramic Production in the Canadian Arctic through Petrographic Analysis
Prior to European contact many Inuit groups produced pottery, largely in the form of cooking pots and oil-burning lamps. Much of the research on Inuit ceramics has focused on how their material characteristics reflect potters’ technical strategies in an environment unconducive to ceramic manufacture. Recent theoretical approaches to the study of ceramic technology recognize that choices made by potters during the manufacturing process reflect not only functional considerations but also the knowledge and social context of potters. Ceramic petrography provides information on both provenance and human technical knowledge, and is also particularly suited to comparative characterization studies of coarse earthenwares, like Inuit ceramics, that contain a range of geological and biological compositional components. However, petrography has seen only limited application in arctic archaeological contexts. Here, we present the results of a systematic analysis of Inuit ceramic technology across the Canadian Arctic, which provides insight into the processes of the initial Inuit migration into the Canadian Arctic from Alaska, and subsequent social and historical developments in Inuit culture.

Mooney, James, Todd Kristensen (Matrix Research Ltd. and Department of Anthropolog) and Keary Walde (Heritage North Consulting Services, Fort St. John,)

Historical records and archaeological finds indicate the Yukon experienced widespread and complex culture contact ranging from pre-contact trade between coastal and interior First Nations to an influx of diverse ethnic groups during historic-period gold rushes. Recent discoveries of Chinese coins minted in the early fifteenth, late seventeenth, and early eighteenth centuries have rekindled interest in their protohistoric and early historic modes of transport from China to the interior of the Yukon and northwestern British Columbia. Russian and British trading may have provided the link between China and coastal Tlingit peoples who carried or traded the coins into the interior. Historic Chinese placer miners in the late 1800s and early 1900s may have also carried these coins with them as lucky charms, amulets, or gaming pieces. While small components of site assemblages, the coins represent significant and expansive patterns of culture contact and movement in the North.

Mooney, Susan Moorhead

[326]  Heritage and Culture Essential Skills (HACES) at Whitehorse Correctional Centre (WCC), Yukon Territory, Canada
Heritage and Culture Essential Skills (HACES) is a community-based program at Yukon College designed to build capacity in order to manage, interpret, and celebrate First Nations heritage resources in the Yukon. Over the past five years, this program’s unique approach has encouraged participants’ personal development and facilitated improved capacity to manage local heritage resources in seven different Yukon communities. During the fall 2013 semester, HACES was offered to students at the Whitehorse Correctional Centre for the first time since the program’s inception. The program delivery presented many challenges, but it also provided an opportunity to integrate community partnerships with hands-on learning for inmates prior to release. Students developed essential skills in the areas of reading, writing, document use, numeracy, and oral communication, while exploring culture and heritage resource management and completing a group project.

[18] Artifacts and Assemblages from Reach 12A of the Navajo-Gallup Water Supply Project
The analyses of ceramic, chipped stone, faunal bone, floral remains, and ground stone artifacts from three sites along Reach 12A of the Navajo-Gallup Water Supply Project north of Gallup, New Mexico have been completed and provide a basis for examining those sites in more detail. Two of the sites are within a Pueblo II Chacoan community, and their artifact assemblages are considered within that context to assess whether they resemble those from other Chacoan communities, or are distinct in some ways. The third site dates to the Basketmaker III period, and materials from that site are compared to those from the Pueblo II sites to examine the effect of the Chacoan sphere of influence on this area.

Moore, Jerry (CSU Dominguez Hills)
[246] In the Desert between the Seas: Environmental, Social, and Ritual Factors in Hunting and Gathering Settlement Systems in Baja California.
Michael Jochim’s seminal 1976 book, Hunter-Gatherer Subsistence and Settlement: A Predictive Model, influenced several decades of archaeological studies of settlement strategies among foraging societies, including my archaeological surveys in northern Baja California. This paper summarizes results of archaeological investigations in a cross-peninsular research area from the Pacific coast across the Sierra San Pedro Martir to the Gulf of California. Although these three areas have received varying levels of research, specific settlement patterns support a model of transhumant mobility as a response to seasonal and geographic variations in food resources, water supplies, and social resources. Although additional research is necessary, available data suggest a pattern of transhumant mobility was in place before 5000 BC and remained a fundamental strategy in this portion of the Baja California peninsula until Spanish contact.

Moore, Christopher (University of Indianapolis) and Christopher Schmidt (University of Indianapolis)
[194] Dwelling on Abundance in the Ohio Valley Archaic
Archaic period studies in Eastern North America typically address resource availability and abundance in environmental terms. Patches or ecotones are considered resource rich if they exhibit a high diversity of available resources or relatively high yields of particularly productive resources. Explanations of Archaic settlement patterns often juxtapose these ‘rich’ zones with areas characterized by fewer or less diverse (i.e., scarcer) resources, arguing that hunter-gatherers were either pushed out of these zones or pulled toward the resource rich zones by changing climatic conditions. In this paper we examine hunter-gatherer sites in and around the lower Ohio River valley and argue that the material and biocultural records of Archaic peoples in this region indicate healthy populations and little to no evidence of scarcity in either subsistence resources or material goods. Rather, hunter-gatherers appear to be well stocked with abundant foodstuffs, raw materials, and tools. Contrasting the assumption of scarcity common in many Archaic period studies, this paper adopts a dwelling perspective and examines the degree to which Archaic hunter-gatherers in the lower Ohio valley experienced a ‘giving environment’ and how this interpretation of the Archaic lifeworld contributes to more nuanced understandings of site use, health, and artifact distribution patterns.

Moore, Katherine (University of Pennsylvania)
[250] Coevolution of Animals and Plants in Early Andean Agriculture
Domesticated plant taxa in the Andes include a suite of plants from tropical lowlands and hardy tubers and pseudocereals from cooler zones. Domesticated llamas and alpacas arose from wild camelids in cold montane grasslands. How did these elements come together into an economic powerhouse during the Late Preceramic? Work at Panaulauca (Junin, Peru) at the high-altitude margin of this process, suggests aspects of intensification upon plants and animals that led to the domestication of local species. Using zooarchaeological data, I examine the role of plant selection and harvesting on grazing ecology, water availability, and nutrient cycling of the early domestic herds. These inferences are based on herb composition, body size changes, tooth wear rates, and stable isotope ratios from bone collagen. These zooarchaeological measures, in turn, relate to Deborah Pearsall’s paleoethnobotanical evidence from the
same deposits, including the diversity of wild plant taxa and foraging locations, the use of dung and sod fuel, the selection for larger tuber size, and the introduction of tropical crops in later periods.

Crystal Artifacts and Production in the Middle Cumberland Region of Tennessee

Artifacts made from fluorite and calcite crystals represent an extremely small percentage of items recovered by antiquarian and modern excavations within the Middle Cumberland region of Tennessee. The six specimens documented to date include four earplugs, one bird effigy pendant, and one bead from four different Mississippian period sites. Mineral vein deposits across the study area contain fluorite and calcite. There is no evidence these crystals were available from surface exposures, but the karst topography of the Central Basin and surrounding Highland Rim physiographic provinces results in numerous caves and sinkholes potentially mined for suitable crystals. Source studies are needed to assess whether these local crystals were used to make the Middle Cumberland artifacts. The recent recovery of crystal earplugs and raw calcite crystals while processing soil samples from 2005-2011 MTSU excavations at the Castalian Springs mound center represents the first evidence for crystal production as an activity within the Middle Cumberland region. Evidence of crystal production has been identified at mound centers in the adjacent lower Ohio River Valley, including Kincaid and Angel. As laboratory work is on-going, it is premature to characterize the Castalian Springs crystal production until all soil samples have been processed and artifacts tabulated.

Spatially Explicit Fire and Erosion Histories from Tributaries to the Sigatoka River, Viti Levu, Fiji: Preliminary Evidence from the 2013 Field Season

The transformation of terrestrial ecosystems on Pacific Islands after settlement has intrigued scholars for decades. Although sediment cores from lakes, ponds, peats, and lagoons have yielded long, continuous, and well-preserved pollen records of past vegetation communities, the locations suitable for continuous pollen records do not always allow for testing spatial variability in human-environmental impacts. Such spatially explicit evidence is necessary to test human behavioral ecology models about the transition from low-level food production and foraging in coastal settings to intensive, inland agriculture. We are assembling multi-proxy records of fire and erosion histories from low order tributaries to the Sigatoka River that allow us to connect the dynamic histories of agricultural clearance and maintenance with archaeologically known occupation histories in different parts of the valley. We present preliminary evidence from a systematic alluvial coring program and laboratory analysis designed to evaluate the spatial consequences of social and economic transformations in the millennia following the Lapita occupation of southwestern Viti Levu.

Moragne, Steven

Extremely Small Things Forgotten: Microartifact Analysis at the Pethick Site

Microartifacts are a seldom sampled but very useful class of data for the interpretation of spatial patterning at archaeological sites. Due to their small size they often exist beneath human notice and are affected by both cultural and natural formation processes differently than larger artifacts. When used in conjunction with traditional data they can lead to new and more robust interpretations. This paper presents microartifact data from the Pethick Site, a multi-component Native American site near Albany, NY. It analyzes microartifact data from both features and the non-feature space surrounding them. Microartifact distributional patterns will be discussed individually and in concert with each other, with the features, and with the macroartifact assemblage. Combined, the multiple classes of data provide a more complete reconstruction and interpretation of the spatial patterning of artifacts at the site.

Morales, Pedro [63] see Casar, Isabel

Morales, Reinaldo (University of Central Arkansas)
The Oldest Rock Art in Brazil?

Debate over the earliest peopling of the Americas tends to resurface periodically as new lines of evidence appear. Recently, paintings at the site of Serrote da Bastiana (Serra da Capivara National Park, Brazil) have emerged as possible evidence of South American rock art as ancient as the famous cave art of Europe, more than 30,000 BP. Very different estimates for the age of this "Serra da Capivara style" rock art have been published, some estimates in disagreement by an order of magnitude. Using multiple lines of evidence and traditional art-historical methodology, this paper reconciles those differences with significant results. The analysis of paintings from 130 local sites indicates there are many "Serra da Capivara" styles. One of these sites, Baixão da Perna I, includes the oldest securely dated rock paintings in the Americas (at the cusp of the Holocene; c. 10,000 BP). Another Serra da Capivara "style" is represented at Serrote da Bastiana (at the cusp of the Formative; c. 3700 BP, millennia later than expected for this "style"). Effective style analysis -- with reasonable expectations of "style" -- can reconcile seemingly contradictory chronometric data and better inform our understanding of culture and its fickle connection to art.

Cultural Change and Continuity in the Maya Lowlands: Understanding the Transition from the Late Preclassic to Early Classic at Mirador Basin

By the end of the Preclassic period a series of social, economic, and political transformations took place in the Mirador Basin. In particular, the populations of the region experienced processes of population decrease and migration, as well as interruption and renegotiations of cultural tradition and social practices accompanied by political change. These trends occur at a time when El Mirador polity was on decline and socio-economic re-adjustments were taking place in other places of the Maya lowlands. After this “crisis”, dubbed the “Preclassic Collapse”, several Maya centers such as Naachtun, Río Azul, Tikal, Dzibanché and Calakmul, among others emerged. Changes in sociopolitical order of the Mirador Basin communities can be documented in the archaeological (architecture and pottery) and the limnological record. This presentation will discuss patterns of socio-cultural adjustment in the Mirador Basin during the end of the Late Preclassic, particularly processes of change and continuity and discontinuity based on recent archaeological investigations in the area. We argue that cultural and social changes which occurred in the transition period at Mirador Basin were very important and decisive in institutionalizing the new forms of political organization that appear during the Classic period in the Maya lowlands.

Bioarchaeological Approaches to the Site “La Cascabel” in Bahia Culebra, Costa Rica (800 - 1550 A.D.)

The archaeological site “La Cascabel” belongs to the bigger archaeological area called Great Nicoya. This area comprised the regions of Guanacaste and Nicoya in the northwestern portion of the modern Latin American countries of Costa Rica and part of the Pacific region of Nicaragua. “La Cascabel” last excavation and posterior analysis between 2007 and 2011 revealed bioarchaeological characteristics like occupational stress with differences between men and woman in relation to economic activities. There was also auditory exostosis in some of the male individuals that indicates their fishing and diving as a part of subsistence strategy. On the other hand, three different moments of occupation were determined and their mortuary practices revealed inhumations. One important question around this site is about their ethnicity and the origin of the individuals that inhabited the area, for this reason we suggest that ancient DNA studies may be essential to understand their conformation.

Moran, Kimberlee (Forensic Outreach)

Implementing the Weldon Spring Protocols in a Full-Scale Post-Blast Field Exercise

The Weldon Spring Protocols provide a methodical approach to tackling large-scale outdoor scenes such as those involving crashes and explosions. While based on archaeological field surveying techniques, the Protocols incorporate law enforcement documentation and chain of custody requirements. In October 2012, a team from the Center for Forensic Science Research and Education in collaboration with the Montgomery County, PA Bomb Squad conducted a full-scale field exercise that involved blowing up a transit bus carrying several "victims" and their personal affects. This presentation will provide an overview of the exercise, how the Weldon Springs Protocols were employed, and the results of the search and recovery effort.

Evaluating Representational Perspectives of Landscape and Adjusting the Historical Gaze of the Basin of Mexico

In the past ten years, the science of remote sensing has exploded in archaeology. Reduced cost and increased accessibility through applications such as Google Earth has made even the least spatially savvy scholar seemingly a spatial guru. These data are updated at a rapid pace, shaping and, indeed, revolutionizing our understanding of how historical processes affect the temporal and spatial scales through which landscape change occurs. What effect does this insight have, however, for the ways in which we trace this transformational process back in time? How can archaeologists not only disentangle the rhythms of landscape but actually document this palimpsest? Focusing on the long-term history of the Basin of Mexico, we integrate different forms of data—aerial photographs; satellite images; historic texts, maps and photographs; oral histories; and archaeological data—to tackle this problem. Our analysis reveals a complex choreography as people, places, and things intersected, collided, replaced, or co-existed across time and space.

Tricks for Integrating Data from Multiple Types of Botanical Residues

When integrating paleoethnobotanical data, what are useful quantitative approaches appropriate to situations with highly variable data quantities, contexts, and sampling strategies? Moreover, in using various botanical proxies, a single aspect is potentially measurable in multiple ways. How can we interpret our findings without over-representing certain data or selling our results short? Archaeobotanical interpretation is particularly complicated by formation processes, clade identification issues, and representation by multiple proxies, even when standardized sampling occurs. The four sites of my study are located Northwestern Honduras, a region with poor preservation due to seasonal cycles of desiccation and inundation as well as generally acidic sediments. For this reason, I pursued several types of botanical residues to provide a more holistic picture of past ethnobotanical practices. In some cases these data proved to be complementary, while in others, corroborative. Drawing on the work of paleoethnobotanists, archaeologists, and statisticians, I describe my approaches to several major issues. I include tactics for integrating multiple and overlapping diagnostic elements, multiple and overlapping clade categories, multiple and overlapping cultural practices, and multiple and overlapping formation processes. For each, I describe the issue, my sampling strategies, my quantitative approach, and a few results from my study.

Plantation Archaeology in Texas: Excavations at the John Sweeny Jr. Plantation

The John Sweeny Jr. Plantation represents a mid-sized, mixed-use plantation indicative of the sugar cane and cotton plantations of Antebellum Brazoria County, Texas. The site has been continually occupied since the 1837 construction of the house; however, the family perpetually sold off portions of the 2680-acre estate after the Civil War. Only 762 acres of the original plantation are located within the area available for study. Excavations at the plantation focused on areas within the immediate vicinity of the house in order to identify intact features that can be directly related to previously identified areas of high artifact density and discrete activity areas (i.e. cisterns, privies, kitchen/refuse middens). This paper presents the results of these investigations and an interpretation of the organization of domestic, service, or any industrial structures that were once present within the site area, comparisons between planter, overseer, and slave populations, and the variations between antebellum and postbellum deposits at the site. Additionally, the archaeological materials and features from the John Sweeny Jr. plantation site are compared with those from notable and well-studied plantations within the area.

Punctuated Occupational Trajectories at Altitude in Western Wyoming

When discovered in 2006, High Rise Village piqued substantial interest due to its elevation, the abundance of house features at the site, and its apparent similarities to the alpine villages of Nevada and eastern California. Recent research has revealed, however, quite different behavioral patterns. It has a longer and deeper period of use, was likely focused more on resource extraction in the immediate site area, and was characterized by much more sporadic, short term occupations than its Great Basin counterparts. This pattern consequently represents a previously- unrecognized subalpine component of a regional Late Holocene settlement pattern characterized by seasonal transhumance, residential feature construction, and increasing diet breadth that ultimately reflects the substantial diversity of hunter-gatherer adaptations to altitude. This pattern also appears to have manifested in several areas across mountain-intermountain western North America during the late Holocene.

Archaeological Blogging: Theory, Methods, and Future Directions

In the space of only a few years archaeological blogging has grown from a quiet conversation between friends to a sometimes fractious cacophony of organizations, companies, field schools, institutions and individuals, operating on several platforms, with varied media on an international stage. Alongside this growth is the increased requirement from funding agencies such as the NSF and Marie Curie for outreach activities related to research. What is the value of this kind of digital outreach to stakeholders and how does it compare to other types of publications and academic service? What does archaeological blogging contribute to the larger discourse in the field?

In this paper I provide a holistic view of blogging, with special attention to social networks and authority in digital media. I follow the trajectory of digital outreach in community archaeology, and offer both a current overview of the growing archaeological blogging community and productive future directions for the medium. As the previous organizer of the 2011 SAA session regarding Blogging Archaeology, I provide context and perspective regarding the state of digital media for public outreach in archaeology.

Morgan-Smith, Maggie (University of North Carolina at Chapel Hill)

Creating Ties, Incurring Debts: Exploring the Role of Life Events through Archival Documents and Oral History from Rancho Kiuic, Yucatan, Mexico

Using archival and oral history data, this paper considers the role of events such as baptisms and burials as both debt maintenance and placemaking activities at Rancho Kiuic; an 18th-20th century Yucatec Maya landed estate, abandoned by its laboring population in the mid 20th century. The funding of life events by landowners has long been understood as essential to maintaining systems of debt on historical landed estates in the Puuc. In this paper, I suggest that the celebration of such events, evident in archival documents and oral history, also served to create ties to the Rancho for the laboring population that exist into the present. Although former residents and their descendants recall a history of oppressive labor conditions and marked inequality between themselves and the Maya-speaking landowning family, the population still actively connects with their old community through the use of its cemetery. The Rancho thus provides an alternative landed estate model for exploring the complexities of relationships to place and landowner in indebted contexts.

Assessing the Daily Economy of an Emergent Maya Polity: Ceramic and Obsidian Data from the Motul de San José Area, Guatemala

Detailed artifact analyses highlight a complex economy in the Late Classic Motul de San José area of lowland Guatemala. In this paper, we draw on ceramic (petrography and modal analysis) and obsidian (chemical sourcing, conservation indices, and core distribution) data to explore changes in local economic systems following the Tepeu 2 Late Classic emergence of Motul de San José as the area political capital. Data from five sites representing all levels of the local settlement hierarchy indicate both changes and continuities to ceramic and obsidian production and distribution systems. In particular, area-wide shifts are noted in both the ceramic and obsidian data from subordinate sites between Tepeu 1 and Tepeu 2 times. These shifts are tied to the changes in the local political structure. The presence of distinct obsidian and ceramic assemblages at the political capital, however, suggests that the economy of
the Late Classic Motul polity was heterarchically structured, with potentially disarticulated distribution systems servicing, on the one hand, the emergent Motul elites and, on the other, the residents of smaller subordinate settlements.

Morrison, Mick (Flinders University) [271] Shell Mounds and Niche Production Strategies

Shell mound sites constructed by Aboriginal peoples are a common feature of Australia’s tropical coastal landscapes. Recent research indicates that these sites represent new economic strategies linked to social, demographic, environmental, and economic changes in some parts of northern Australia during the last 4 kyr. Previous research highlights the economic significance of r-selected shellfish species—often represented in extremely large proportions in mound sites—because of their ability to rapidly form a large biomass within preferred habitats. Here, I argue that shell mounds near Weipa represent a new production strategy targeting ecological niches, in this case intertidal mudflat ecosystems. This strategy was highly dynamic, varying in intensity on a sub-decadal basis in response to seasonal and spatial variability in shellfish biomass within local estuaries, and as such, was dependent upon quite detailed knowledge of the character of local ecosystems. These strategies were also reliant upon social networks and the ability to mobilize larger gatherings of people to coincide with localized resource gluts, while spatial and temporal variations in the distribution of resources became a geopolitical factor within local political economies. These socially constituted economic strategies are potentially emblematic of broader economies in the region during the late Holocene. [331] Discussant

Morrow, Juliet (Arkansas Archeological Survey) [30] Evidence for Spirituality during and after the Clovis Diaspora

For this study, the term “spirituality” refers to a dimension of human experience wherein an individual imagines the self within a broader context of being. Spirituality implies separation between the body and the soul, as well as between the mundane and the sacred. This presentation is a survey of the available evidence for spirituality expressed by Late Ice Age hunter-gatherers during and after the Clovis Diaspora, from circa 14,000 to 10,000 years ago. Key sites discussed include Anzick (Montana), Buhl (Idaho), Sloan (Arkansas), Caradoc and Crowfield (Ontario), Charlie Lake Cave (British Columbia), and Wilson-Leonard and Arch Lake (Texas), among others.

Moses, Victoria (University of Arizona) [332] Interpreting Ritual Practice through Zooarchaeology at Sant’Omobono, Rome

The religious significance of the Area Sacra di Sant’Omobono in Rome, Italy is evident in the continuous use of the site for sacred purposes from the 6th century BCE construction of the Archaic temple through the use of the modern church that stands at the site. Despite its long history of excavation, the faunal remains at S. Omobono have been extremely understudied. To interpret the religious beliefs and ritual practices of the early phases of use, this research focuses on faunal remains and other associated artifacts, such as votive vessels. Fauna is ideal for understanding religion and ritual as it not only leave ample archaeological evidence of the ritual practice but aids in understanding the important relationship
between human, animal, and supernatural. The systematic analysis of fauna recovered in previous excavations of the archaic temple as well as from current excavations of The Sant’ Omobono Project indicate that animals played a significant role in communion between human and supernatural forces. While current excavations suggest a reinterpretation of previously identified sacrificial animals as animal remains likely used for construction fill, the taxa and age demographics present, in conjunction with other artifacts, indicate the ritualistic nature of these remains.

[160] The Archaeology of Pacific Herring in Alaska
We aim to develop a more complete understanding of the ancient Alaska Native use of Pacific herring (Clupea pallasi) to better assess the historical abundance, biogeography and genetic diversity of herring in the past. The ultimate goal is to improve herring fisheries management to benefit a wide range of stakeholders in the Arctic, Subarctic and beyond. Ninety herring bone samples from 17 archaeological sites in Alaska spanning 9000 radiocarbon years have been tested. Ancient DNA recovery has been high, and study of SNPs (single nucleotide polymorphisms) appears to be the most effective way to assess genetic population structure from ancient remains. Preliminary evaluation as to how the Alaska samples relate to others in British Columbia, Washington State, and the northwestern Pacific will be presented. The results should have implications for fisheries policy and practices, Alaska Native subsistence rights, and herring conservation.

[189] It’s Complicated: 1,250 Years of Shaft and Chamber Tombs in Northwestern Jalisco
Eighteen years of archaeological investigations in the northwestern part of Jalisco have resulted in the excavation of some 33 un-looted and 11 partially-looted shaft and chamber tombs that span the period of at least 820 B.C. to A.D. 430. During this 1,250 year span there is notable variation in the form of the tombs, the kind and quantity of offerings deposited in the tombs, as well as the number of deceased included and the condition of their remains at the time of burial. Suggestions are offered regarding the significance of this variation.

[249] An Integrated Study of the Eastern Anatolian Obsidians (Sources and Diffusion): The Geobs Program
The GeObs project proposes an integrated and multi-disciplinary approach to study the exploitation of the Eastern Anatolian obsidian by ancient groups for the manufacture of tools and prestige objects, and its spatial diffusion through exchange networks among communities across the ancient Near-East (including Anatolia and Caucasus). Because of the imprecision and/or the lack of data, it is, until now, impossible to properly understand obsidian diffusion from its origin to its discard; i.e. from the geological sources to the archaeological sites. The aim of the project is to establish a detailed database and geographical information system of the obsidian sources in eastern Anatolia. We thus propose an integrated and pluridisciplinary approach for obsidian sourcing based on:
- Intensive field research in order to preciselu identify the morphological and volcanic settings of the studied obsidian sources.
- Multi-methods characterization of obsidian associating chemical (using LA-ICP-MS, XRF methods) as well as physical properties (magnetic properties, petrography, mineralogy). All the results will be
interpreted in link with the results of the field investigation.
- Using the methods of spatial analysis we will try to understand the diffusion of the obsidian during prehistoric times, from its geological origin to its deposition in archaeological sites.

[152] Building Capacity for Co-Created Digital Moviemaking through Youth Programs
The Urban Archaeology Corps is a work experience program conducted through a partnership between the National Park Service and a community-based partner, Groundwork Anacostia River DC. It draws on archaeology as a tool of civic engagement to offer youth from diverse backgrounds an opportunity to learn about national parks and their untold—or little known—stories. Each UAC participant creates a short digital film to "speak back" to the NPS and reflect on something particularly meaningful to them, be it a facet of the park's history, a park stewardship concern, or a wakeup call to the communities surrounding parks. Training in and use of digital media is thus an essential component of the co-creation process. This paper is a case study in building capacity in youth programs for co-created digital products that help the NPS, its partners, and their communities to share in the stewardship of archeological resources and public lands.

Moyes, Holley (University of California, Merced)

[277] The Dark Side of Las Cuevas: A Ritual Journey
Archaeologists have paid little attention to architecture in ancient Maya cave sites, though many, if not most caves exhibit some degree of modification. Nowhere is this better exemplified than at the site of Las Cuevas. On the surface Las Cuevas appears to be a typical Late Classic, medium-sized, administrative/ceremonial center. But, this site has something that most others do not—a large cave system that runs beneath the main plaza. The massive entrance to the cave sits in a sinkhole directly below the eastern pyramid of Plaza A. Formal architectural modifications including platforms with plastered surfaces, stairs, and terraces surround a natural spring in the Entrance Chamber. The cave's tunnels begin at the rear of the chamber, twist and turn, and eventually circle back into the entrance culminating at a high window that overlooks the spring. Throughout the tunnel system blockages and walls restrict access to deeper areas. In this paper I suggest that architectural modifications to the tunnel system were designed to create a performative space that guided participants through an Underworld journey.

[265] Across the Landscape: An Examination of Environmental and Cultural Changes through Analysis of Late Prehistoric Lithic Assemblages from north-central Oklahoma
The area of north-central Oklahoma is an under studied part of the Southern Plains, especially during the Plains Woodland and Village periods. A model proposed for the mobility and settlement practices of the prehistoric groups of the area was evaluated through analyses of lithic assemblages from four sites. The sites were selected from adjacent, but contrastive biomes thought to have been occupied by groups that followed a seasonal round in which grassland and woodland resources were exploited through an embedded procurement strategy during peaks in resource availability. These included the Daniels and Von Elm sites from the Bluestem Prairie and Big Hawk Shelter and Copperhead Cave from the Cross Timbers. The lithic analysis focused primarily on the identification of chert varieties and locations, the amount of cortex present, and the size/weight of lithic elements. These attributes were presented as proxies in evaluating the mobility and procurement practices of people in the study area. The results from the analysis suggest that Late Prehistoric groups in north-central Oklahoma were living in temporary, seasonal sites relying on an imbedded rather than logistical procurement strategy. This was a time-transgressive pattern present during both Plains Woodland and Village periods.

Mt. Joy, Kristen (Texas Army National Guard)

Cultural Resource programs in public agencies face a constantly changing funding and policy
environment. Most programs primarily focus on regulatory compliance, which often limits exploring the myriad of ways archaeology gets done. Advances in the applications of geophysical and geospatial methods and techniques often outpace the ability for agencies to incorporate them into their planning and programming. A larger obstacle comes when misunderstanding of the normal trial and error in scientific advances leads to agencies limiting approaches to traditional cultural resource management. The end result is agencies may be missing out on valuable tools to identify and provide information on historic resources that may allow application of more efficient and effective management strategies. In addition to their uses for guiding and focusing investigations before shovels touch the ground, non-invasive techniques are desirable to many communities that prefer to avoid disturbance to sensitive sites or burials. This paper looks at how agencies can adapt modern technology into their programs and demonstrate to non-professionals their power and value as management tools.

Mueller, Melissa (Texas A&M University, Center for the Study of the First Americans)

Taphonomic Interpretations of Burned Bones from the Susitna River Basin, Alaska

This presentation provides a report on the zooarchaeological and taphonomic analysis conducted on faunal material from the archaeological sites HEA-455 and HEA-499, located in the upper Susitna River basin, central Alaska Range. Faunal remains include approximately 11,323 faunal specimens; however, only 16 were minimally identifiable to element and taxon. Specimens were each less than 7 mm in size due to heavy fragmentation. The high degree of fragmentation limited attempts to identify these faunal remains, yet a taphonomic analysis on the degree of burning seen in these faunal remains indicates possible human activities and behaviors related to subsistence and site maintenance. Based on interpretations from experimental studies in the literature on the effects of burning bones in fires, the bone fragments from these two archaeological sites appear to be burned directly from human site activities. The results presented here provide insight into prehistoric subsistence and site activities in the mountainous Alaska Range, as well as a better understanding of taphonomic processes in play in this environment.

Mueller, Natalie

Developing Domestication Criteria for Crops with Knotty Morphologies: Polygonum in the Eastern Woodlands

By developing morphological criteria for recognizing domesticated plants, archaeologists are able to find direct, datable evidence of past agricultural practices. Annual seed crops often exhibit a straightforward domestication syndrome in response to human selection that includes larger seeds, reduced germination inhibitors (seed and fruit coats), synchronized fruiting, decrease in mechanisms for seed dispersal, and a more erect growth habit. Despite these well-established indicators, some crops continue to elude our efforts to develop criteria for domestication. I present preliminary results from my attempts to establish morphological criteria for domestication for one such crop, knotweed (Polygonum sp.) that was cultivated for at least 2000 years in Eastern North America. In order to establish domestication criteria for this extinct crop with complicated seed morphology, I am employing morphometrics and texture analysis coupled with experimental cultivation and observations of modern plants. This study also has the potential to enrich our understanding of the dynamics of domestication through agricultural practice in general.

Further Research on Floodplain Evolution Associated with the Site of Rio Viejo, Lower Rio Verde, Oaxaca, Mexico

The Rio Verde is one of the largest rivers on Mexico’s west coast with its upper drainage containing the important archaeological site, Monte Alban. The lower portion of the drainage contains the important Rio Viejo site along with others. Previous geoarchaeological research showed that the river shifted course and altered the environment over the last few millennia due to an influx of sediment from the highlands. The Rio Verde has shifted from the west to its present location but did not appear to have ever shifted to the east. A recent rise in the water table caused by an irrigation project revealed, on Google Earth imagery, many buried meanders east of the river. Sourcing the origin of sediments from these abandoned meanders provides insights into the geomorphic evolution of the region and possible effects on regional archaeology. Sand samples were collected from both the abandoned meanders and from modern depositional environments. Observation and measurement of sand mineralogy provides answers to the origin of the meanders. Sediment mineralogy suggests that these meanders represent either former courses of local streams or an amalgamation of coastal plain fluvial systems. The sediments do
not appear to be associated with the Río Verde.

[126] Born into Poverty: The Short Lives of the Destitute, Diseased, and Starving Infants of the Erie County Poorhouse

In the summer of 2012, a salvage excavation at the South Campus of the University at Buffalo resulted in the recovery of the human remains of over 380 individuals, fifty-four of who are infants. These children are associated with the Erie County Poorhouse Cemetery (1851-1909). Initially developed to address the growing issues of poverty, the poorhouse failed to meet its goals. While poorhouses varied, policies regarding work therapy, abuse of inmates, placement in orphanages and separation of the familial unit may have served to further already discriminatory practices against the "other," including the impoverished, mentally and physically disabled, and those with immigrant-status. In recent decades, the lives and deaths of children have received significant attention in the anthropological literature. As it relates to the health of past populations, much of this research has focused on the recognition that children are among the most biologically sensitive to cultural change. Born into poverty, the vulnerability of poorhouse infants may be evidenced in their early deaths. Using structural violence as a framework, this research integrates data from the archaeological, historical, and skeletal records to determine age-at-death patterning among the poorhouse infants and to address the ultimate causes of their morbidity and mortality.

[104] LIP Fortifications in the Moche Valley of Peru: New Perspectives

The Late Intermediate Period (A.D. 800-1470) in the Moche Valley of Peru witnessed the political consolidation and expansion of the powerful Chimú Empire centered nearby at Chan Chan. Roughly coinciding with the Chimú florescence on the coast, a variety of specialized defensive sites and fortified settlements were constructed and occupied in the middle and upper reaches of the Moche Valley and some of its tributaries. These fortified sites have been used in previous scholarship to describe the Chimú conquest and consolidation of the Moche Valley as well as the structure of its frontier with the highlands. In the 2010 and 2011 field seasons, the author mapped and conducted surface collections at a middle valley Chimú fortification called Fortaleza de Quirihuac. Using a synthesis of this original data, preliminary survey done in 2013, and previous scholarship, the author aims to present a reassessment of Chimú expansion and consolidation in the Moche Valley as well as the varied nature of imperial interactions with valley and highland communities.

[242] Ho’omaka hou (To Begin Again): Re-Dating Early Hawaiian Settlement Sites of Southern Hawai’i Island

Beginning in the 1950s, archaeologists working in the Hawaiian Islands initiated major research projects directed at identifying the initial settlement of the archipelago. Southern Hawai’i Island was central in this effort because sites there provided the archipelago’s first material culture-based chronology, which was based on changing frequencies of fishhook types anchored in time by radiocarbon dates. But, these initial efforts have been sidelined in more recent discussions about early Hawai’i due to serious problems with
chronometric hygiene that have invalidated previously reported dates. In this paper, we present the results of the re-dating of key early sites in southern Hawai‘i Island excavated by Bishop Museum archaeologists that include layers initially bracketed to within the colonization period of the Hawaiian Islands. Acquiring these new dates on carefully selected samples, along with a re-examination of the material culture collected, gives us the opportunity ‘to begin again’ and investigate not just when people arrived, but what life was like for Hawai‘i’s founding communities.

[68] #Archaeology#Makingitrelevant
Since opening our doors in 1998, the San Diego Archaeological Center has become a nationally recognized leader in the curation of archaeological collections. Our goal is to sustain an archaeological center where artifacts will not only be cared for, but where scientific research can be facilitated and the public can enjoy learning about the prehistory and history of the San Diego region through educational programs and museum quality exhibits. Today, through benefits provided through social media, archaeology is the ideal tool for teaching global awareness, civic and environmental literacy and adaptability, as well as cross-disciplinary thinking and social and cross-cultural skills.

Munoz, Olivia (Université de Paris 1 (France))
This paper aims to highlight recurring patterns in the 'management' of 3rd millennium BC collective graves from the Oman Peninsula. Data from the recent excavations of several collective tombs and analysis of skeletal material recovered will be compared to sites and material found elsewhere on the Oman Peninsula. The evidence of mortuary rituals identified in these collective tombs reflect an increasing complexity of burial practices throughout the 3rd millennium, especially during the second half of the 3rd millennium BC. Evidence will include the manipulation and removal of human remains to adjacent pits, cremation, and to a lesser extent, defleshing. These practices may stem from the need for more space in the tombs where a growing number of individuals were placed, but they also contribute to melt individuals into the community of the ancestors and strengthen social cohesion among the living. Furthermore, the widespread prevalence of common solutions adopted for the maintenance of the collective graves throughout the Oman Peninsula show that the ideology underlying these practices was probably shared by groups with different economic orientations, attesting of a strong cultural homogeneity.

Munoz, Victoria (Shumla Archaeological Research and Education Center) and Jeremy Freeman (Shumla Archaeological Research and Education Center)
[199] A New Dimension in the Study of the Lower Pecos Canyonlands Rock Art
Shumla Archaeological Research and Education Center has been engaged in an intensive rock art documentation project in the Lower Pecos Canyonlands of Texas since 2009. It is a daunting task to not only preserve the imagery and its context for future generations, but to capture data in a way that is useful for detecting patterns in the archaeological record. To meet this challenge, Shumla’s research team collects extensive attribute data on each pictographic figure, documenting and entering information into our searchable rock art database. This database is capable of running complex queries to identify patterns in the rock art assemblage. We map the precise location of each figure using a Total Data Station and GPS, integrating this information with our figure attribute data. Using ArcGIS we will begin examining spatial relationships among figures and identify patterns in motif association and their distribution across the landscape. GIS and spatial analysis opens the door to exploring possible associations between individual rock art elements and the “dirt” archaeology. This information provides greater insight into the meaning and function of the art and the lifeways of the people who produced it.

Munoz, Lizette (University of Pittsburgh), Karen Durand (Haciendas of Nasca Archaeological Project (PAHN)) and Brendan Weaver (Vanderbilt University)
[256] “Eat this Bread, Drink this Cup”: Preliminary Discourse on Foodways at the Jesuit Wine Estates of Nasca, Peru
Using archaeological datasets that relate directly to foodways is an extremely useful prism to assess the impact of religious taboos, the expansion of global markets, and the emergence of new ethnic identities in multi-cultural settings. The preliminary results of the 2012-2013 excavation season of the Haciendas of Nasca Archaeological Project offers the prospect of branching our understanding of colonial foodways beyond the Native Andean/European dichotomy – an opportunity to understand, through material correlates of domestic production, consumption, and discard, how power was brokered on coastal haciendas, where the majority of the labor was enslaved and of African descent. Enslaved Afro-Andeans may have adopted foodways which share common traits with other groups in the Andean region: creole, mestizo, and native Andean, but were themselves distinct due to the special power dynamics present on an estate where slavery was the dominant productive paradigm. Using data from ethnohistorical sources and the preliminary results of our ceramic, paleoethnobotanical, and zooarchaeological analyses we examine the way administrators provisioned enslaved laborers with daily sustenance, as well as the potential ways that enslaved individuals and families may have supplemented their diets, perhaps through the hunting and husbandry of small animals and the planting of personal gardens.

A Paleoenvironmental Record of Prehistoric and Historic Land Use from the Cahokia Region

Cahokia emerged as a major agricultural and political center in the central Mississippi River valley at 1050 CE, but the entire region was almost completely abandoned by 1350 CE. Environmental changes, namely resource depletion, flooding, and/or drought, have previously been invoked as important factors in Cahokia's emergence and decline, although few paleoenvironmental records exist from this region. Here, we present a multi-proxy paleoenvironmental record (pollen, δ13Corg) from Horseshoe Lake, an oxbow lake adjacent to Cahokia. The Horseshoe Lake record tracks the abrupt removal of floodplain and upland forests and the expansion of indigenous seed crop production beginning in 450 CE, followed by the gradual intensification of maize agriculture through to the abandonment of Cahokia at 1350 CE. Reestablishment of forests followed regional abandonment by Mississippian peoples, with Euro-American settlement generating another episode of deforestation and agricultural activity beginning in the 17th century. Widespread deforestation of the region centuries before Cahokia's emergence shaped resource availability for Woodland and Mississippian groups, but we find no palynological evidence of abrupt resource depletion during the Mississippian period. We also find no evidence of drought associated with Cahokia's abandonment, but do find evidence of a large flood at 1200 CE that surely affected Mississippian communities.

Laser Scanning as an Analytical Tool Applied to 3D Digital Imagery in Maya Archaeology: La Blanca and Chilonche (Guatemala)

Laser scanning is a powerful tool for archaeological and architectural data collection that is opening new horizons in the analysis and interpretation of archaeological excavations, especially in the field of metrically accurate 3D digital imagery. Scanning and the digital models it creates not only contribute to answer questions asked of the archaeological record but also facilitate cultural heritage documentation and preservation. In this sense, La Blanca project, which has been conducting archaeological research and promoting cultural heritage in La Blanca and other neighbouring archaeological Maya sites of the Mopan valley region, as Chilonche since 2004, has employed laser scanning technology with the purpose of obtaining a more meticulous and careful record of Maya architecture for archaeological interpretations. The models obtained in La Blanca and Chilonche are also useful instruments for planning future excavations and can be used in exhibitions and multimedia.

The Application of Forensic Archeology in Mexico: Methodological Proposal for Excavating, Recording and Recovering Cadavers and Evidence Related Within Mass Graves Associated to the Drug Cartels

This research aims to develop a methodology to properly excavate, register, exhume and recover circumstantial evidence, material and biological, interrelated within mass graves that are directly or indirectly associated with the increase of disappearances and murders carried out by the drug cartels and organized crime syndicates in Mexico. The study attempts to emphasize the importance of regional studies and the continuous consideration of the delicate social issues that every region retains. Through
archaeology and its application in the forensic field, it seeks to optimize and facilitate police investigations, but above all, to understand the criminal behavior imprinted in the evidence we find and the message this specific type of context delivers.

[B150] Beyond Chavín: The Balkanization of Early Horizon Societies in Coastal Ancash, Peru
This paper explores regional developments after the demise of the Chavín phenomenon in coastal Ancash, north-central Peru, during the second half of the first millennium B.C. At that time, complex societies along the coast of Peru experienced profound reorganizations including the emergence of a series of communities integrated through multi-scalar social, economic, and political networks. We focus on the Nepeña Valley of coastal Ancash, a region traditionally associated with the hegemony of Chavín. Here, recent research has brought significant data to assess the sociopolitical climate after the loss of Chavín religio-political influence. We are particularly interested in exploring the diversity of human strategies in response to the reorganization of inter-regional interactions. Within the past decade, work at the sites of Huambacho, Caylán, Samanco, Kushipampa and the surrounding Moro pocket have pointed to two distinct political traditions occupying the upper and lower valley, respectively. These differing traditions are illustrated by distinct settlement patterns, and spatial distributions of sites, as well as differing architectural techniques and ceramic styles. We explore how these two cultural spheres negotiated the processes of balkanization following the demise of Chavín, and compare their strategies to other regions in Peru.

[B236] Human Hunting and Landscape use in the Jordanian Eastern Highlands during the Early Epipaleolithic
We investigate the effects of the Last Glacial Maximum (~25-18,500 cal. BP) on Early Epipaleolithic human adaptations in the eastern Levant (Jordan) through the study of faunal remains from four Early Epipaleolithic sites excavated as part of the Western Highlands Early Epipaleolithic Project. Landscape use is monitored by examining site occupation intensity using measures of dietary breadth, prey mortality and carcass exploitation. Our data reveal a mobile human adaptation focused on the hunting of high-ranked adult game, and intensive carcass use. Comparisons with Epipaleolithic sites across the southern Levant reflect significant variation related to local environmental and geographic conditions.

[B305] Chasing Chocolate: Recent Investigation of Collapse Sinkholes (Rejolladas) as Loci of Cacao Production in the Northern Maya Lowlands
Rejolladas are collapse sinkholes with bases above the local water table that are densely distributed over portions of the Northern Lowlands of the Yucatan Peninsula. Typically they sustain moist microclimates in comparison to the surrounding terrain, as well as thicker soils allowing them to be used for more intensive agriculture. The paper presents a model of use and importance of the rejolladas based on archaeology, geomorphology, soils, botanical evidence, water table position, and geographic location in the Northern Lowlands. Specifically examples will be discussed from the sites of Uci-Cansahcab, Xuenkal, and near the modern city of Valladolid. Together these data strongly suggest that some of the sinkholes were utilized intensively by the ancient Maya for the production of cacao (Theobroma cacao) in an environment otherwise unsuitable for cultivation. In particular, deeper, steeper rejolladas were more likely to have been used for cacao production.

Munson, Cheryl Ann (Indiana University), Cheryl Ann Munson (Department of Anthropology, Indiana University-Blo) and April K. Sievert (Glenn A. Black Laboratory of Archaeology, Indiana)

[B74] James Kellar, Indiana’s Mid-Century Modern Archaeologist
James Kellar (1922-2003) discovered anthropology while serving in the Navy during World War II. Educated at Indiana University, he turned to archaeology after Glenn Black’s field school at the Mississippian Angel site. His early research focused on county-wide surveys and Woodland stone mounds of the Ohio Valley. His most notable work was directed to Hopewell sites, Mandeville (Georgia)
and Mann (Indiana), and an overview of the one million plus artifacts that Black had excavated at Angel. Wearing many hats – teacher, administrator, preservationist, museum visionary, scholar – Kellar saw his greatest professional challenge to be saving the Mann site from industrial development.

**Classic Maya Bloodletting Rituals in Cultural Evolutionary Perspective**

Recent cultural evolutionary approaches to religion offer novel ways to investigate the existence and proliferation of apparently maladaptive ritual behaviors. However, there are few archaeological studies that examine past religious behavior from this perspective. Classic Maya bloodletting rituals are a widely-discussed example of costly religious behavior, yet little is known about the distribution of these practices, the range of contexts in which they were performed, or the mechanisms and consequences of their spread. In this study, we use generalized linear modeling and social network analysis to characterize temporal, spatial, and contextual variation of bloodletting rituals recorded on Classic Maya hieroglyphic monuments. We show that epigraphic references to bloodletting were not evenly distributed in space and time. We also show that homophily accounts for the spatial distribution of these rituals across the southern Maya region, which implies that inter-polity connections strongly influenced the transmission of bloodletting rituals within Classic Maya society. Collectively, our findings suggest that bloodletting rituals were not uniformly practiced by Maya nobles, but were likely performed in connection with dynastic accession rituals that signaled royal commitments among polities with shared sociopolitical relations. More broadly, this study demonstrates the power of cultural evolutionary theory for investigating past religious behavior.

**Effects of Archaeological Laboratory Extraction and Curation Procedures on Starch Granule Integrity and Morphology**

Archaeological starch research has included considerable experimental work on peri-depositional taphonomic effects of food preparation methods on starch granule integrity and morphology. However, the effects of laboratory extraction procedures on starch granules have received less attention. There are several aspects of common laboratory procedures for which controlled experiments documenting the effects on starch integrity have yet to be conducted or reported. While procedures that negatively impact starch integrity should be modified to minimize negative impacts, those that do not affect starch integrity might be employed in new ways to enhance starch recovery. In this paper, we present the results of experiments quantitatively documenting the effects of particular starch granule extraction and curation procedures on granule integrity and morphology, including sonication, long-term storage in solutions, and others. In cases where results of experiments suggest starch extraction methods may be improved through modification of established protocols, we assess whether modification of procedures actually results in more effective extractions of starch granules from artifacts.

**Time and the History of Occupation in San Bernardo, Durango, Mexico**

The archeology of the present state of Durango has been shaped by the work of several formal research projects, which have helped constitute the identity of this region. However, basic knowledge of the sequence of occupation from prehispanic times to the present is subject for debate. In this paper I discuss time and settlement in the area, presenting recent results from radiocarbon dates and new interpretations of the occupations by ancient dwellers of the northwest region of Durango, never studied before.

Murillo-Herrera, Mauricio (Universidad de Costa Rica) [197]  
**Understanding the Emergence of Community Specialization in San Ramón, Costa Rica**

Previous research in San Ramón, Costa Rica, indicates that pre-Columbian monumental architecture in
this region was not related to high population density, but to ceremonial and feasting activities, in addition to a higher frequency of exchange activities with the Guanacaste region. This paper further explores this issue by closing in on one community with monumental architecture in San Ramón: the Barranca site. This year Barranca was formally and functionally characterized by an intensive full-coverage survey with test pits spaced at an interval of 10 meters. Clay-burnt floors, wattle and daub walls, hearths, internal pathways, house foundation rings, and food remains are some of the features located. Artifactual evidence includes local and foreign objects, and both ceremonial and utilitarian pieces. The analysis and integration of all this information makes it possible to assess the kinds of activities that were most common in different sectors of Barranca, which is key for understanding the role Barranca played in the regional social dynamics of pre-Columbian San Ramón.

Murphy, John [214]  
Resilience in a Wider Sense: How Archaeology Might Benefit from and Contribute to New Approaches to 'Resilient' Systems

The term ‘resilience’ was introduced formally in ecological studies to describe a pattern of alternate regimes through which a natural system might move (the ‘adaptive cycle’). This was extended to socioecological systems, and archaeology, uniquely positioned to study long-term SES dynamics (especially, societal collapse and reorganization) adopted the term readily. Recently the term ‘resilience’ has become widely used in a broad range of other contexts, where it now generally refers to the capacity of a system to respond to challenges; this encompasses anticipation, avoidance, and recovery, possibly including novel advantageous changes to the original structure. Applications in national defense, disaster recovery, and business have pushed these ideas forward, so that now there is an emerging dialogue among these fields and a nascent framework for describing and quantifying ways that complex systems may be ‘resilient’ or vulnerable. This paper considers examples of these new approaches, and asks if they can usefully be applied in archaeological studies and whether archaeology can in return make contributions to these new definitions of resilience.

MURRAY, William [248]  
Marking the Water: Iconography and Environment in Northeast Mexican Rock Art

Water is essential for human survival, but since it has no inherent shape or form, its iconic representation in any media requires graphic conventions which allow its translation via learned cultural codes. It is also evident that much rock art worldwide is closely linked or even directly related spatially to water sources. In desert environments, water is even more critical to survival and the probability that it might be represented in prehistoric rock art motifs is consequently higher. The question is: how might this relationship be marked iconographically? Are there water symbols in rock art? And if so, how can they be identified? Rock art sites in the southeastern fringe of the Chihuahuan desert in the Mexican states of Nuevo León and Coahuila provide an ample repertory of images for approaching these questions in varied environmental contexts. In particular, the sites in Icamole canyon, Nuevo León, Mexico will be analyzed in order to identify specific iconographic associations within this intermontane water course in the Sierra Madre Occidental. These associations may have a broader application on a regional and continental scale.

Archaic Land Use of the Taos Plateau and Rio Grande del Norte, New Mexico

Archaic sites of the Oshara Tradition are common on the Taos Plateau of northern New Mexico. Recent field survey has expanded our knowledge of Archaic sites on the plateau. These sites along with previously recorded Archaic sites in the newly established Rio Grande del Norte National Monument are the subject of study. Raw material selection and lithic technology, in general, as well as site location and reoccupation are examined to explore aspects of Archaic land use including mobility, resource procurement, and continuity of strategies throughout the Early, Middle, and Late Archaic periods.

Murrell, Monica [294]  
From Great Kivas to Great Houses: Early Village Formation and Integrative Architecture in the
Southern Chuska Valley
Aggregated communities appear throughout the Chuska Valley during the Basketmaker III period, with many of these early village sites continually reoccupied into the Pueblo II–III times. Isolated great kivas were often established in association within these communities representing early, large-scale, integrative architecture in the valley. Great houses containing great kivas and walled courtyards associated with the Chacoan system were later constructed in proximity to established Basketmaker III villages. These great houses were overwhelmingly constructed during the Pueblo II period, with only a few examples occupied during Pueblo I times. Although architectural traits distinguish the aggregated communities from great houses, they appear to be established as cooperative units with numerous examples of interaction and exchange apparent in both the Chuska Valley and Chaco Canyon proper.

The Agrarian Landscape of Tikal: A View from Above
Traditionally, archaeological approaches to remote sensing emphasize the identification of prehistoric and historic features sites, architecture or activity areas. Recent efforts in landscape archaeology have expanded the role of remote sensing. This paper describes our efforts to investigate, characterize and classify the agrarian landscape surrounding the largest Classic Maya site, Tikal, Guatemala. We introduce and compare data and techniques we have used in our study. We also introduce our field based approaches used to test and improve our techniques.

The key purpose of our paper is to demonstrate how we are integrating these data in a coupled modeling environment, investigating how changing patterns of land use, agrarian decision making and climate influenced availability and access to natural resources, i.e., soil and water. Importantly, our paper addresses previously unresolved issues about the sustaining area of Tikal, first raised nearly 50 years ago and offers a revised perspective about how the Maya made a living on the agrarian landscape of Tikal throughout the Classic Period.

Muschal, Marlis (University of Iowa)

Sedentism and Expedient Technology: Dismal River Aspect, Kansas
This study seeks to test the proposed link between sedentism and expedient lithic technology. Using collections from two Dismal River Aspect sites in western Kansas, this study will explore the extent to which these lithic assemblages exhibit expedient technological strategies. Explicit expectations regarding tool manufacture, reuse, and discard will enable a suite of testable hypotheses to emerge whereby the connection between sedentism and expedient technology can be clarified.

Musser-Lopez, Ruth (San Bernardino County Archaeological Heritage Association)

"Western Aggregate Row Mound" Type Site
Sufficient evidence exists to identify provisionally an historic site type heretofore not recognized. Virtually identical characteristics are associated with "Western Aggregate Row Mounds" at three separate locations in the western United States including one, quite controversial, the "Mystic Maze." Often confused with giant prehistoric earthen artwork or geoglyphs, Western Aggregate Row Mounds made in "relief" with mechanical scrapers are distinguished from "intaglio" style earthen art associated with prehistoric trails commonly found along the Lower Colorado River. The footprints of Western Aggregate Row Mounds represents historic preparation of aggregate materials for collection with intended use in nearby railroad ballast and bridge caissons.

Mutin, Benjamin (Harvard University)

Uruk presence at Tepe Yahya
The site of Tepe Yahya is located in the southeastern Iranian province of Kerman. The excavated deposits and objects, including tablets, seals and sealing impressions, and ceramics, that are assigned to Yahya Period IVC provide much evidence that connects this period to the so-called Uruk/Proto-Elamite sphere. The site is practically the easternmost marker of this sphere and provides unique data for an
investigation of distant exchange relations, not limited to the interaction with the West, throughout the
Iranian Plateau and Mesopotamia in the period around 3000 BC. Several types of ceramics from Tepe
Yahya that are traditionally affiliated with the Uruk/Proto-Elamite world were submitted for neutron
activation analysis, which was conducted at Oregon State University. This paper reviews the material
culture at Tepe Yahya in the Uruk/Proto-Elamite period and discusses the implications derived from the
preliminary results of the analysis.

Nadeau, Jaclyn (University at Albany), Jessica Watson (University at Albany), Steve
Moragne (University at Albany, New York State Museum), Sean Rafferty (University at
Albany) and Christina Rieth (New York State Museum)

The Pethick archaeological site is located in Central Bridge, Schoharie County, New York. It is the result
of a collaborative research project between the New York State Museum and the University at Albany
and is still undergoing excavation. It is virtually undisturbed with numerous features from several well
stratified components (Rieth et al. 2007; Rafferty et al. 2013). This study presents current research
agendas and addresses ongoing analysis by graduate students and the principal investigators.

Preliminary results on data from several artifact types, including ceramics, lithic debitage, and
microartifacts are introduced. The preliminary results of x-ray fluorescence examinations and activity area
analysis is also discussed.

[65] High-Resolution ‘Desert Kites’ Documentation and Analysis: The Use of LiDAR Scanner in a
Visibly Complex Environment

The Near East “Desert kites” are large-scale built features composed of funnel-like arms leading to a cliff
or into a small deep structure, or into enclosure-like walls several hundred meters across. As the
structures are usually low (1-3 courses high), built of local stones, and set in harsh arid environments,
their construction details are commonly visibly limited and difficult to document. Thus, until recently the
majority of the kites were only mapped via Google Earth data, with no 3D information about their structure
and topographic settings. Isolated cases were mapped and photographed using old traditional
archaeological techniques. For better characterization and study, we introduced a LiDAR scanner to
record and analyze the Negev kites. We documented the architecture and immediate topography
(centimeter level of resolution and accuracy) of eight structures in their natural ‘low-visibility’ settings,
facilitating a wide array of analysis avenues, impossible by previously used techniques. Here we present
the analytical results based on derived 3D models constructed for each kite: characterization and
correlation of arms’ length, entrapped area, inclination, and head structure. We also address volume of
stone construction to evaluate past efforts. Case-studies of intra-site and inter-site analyses are
presented.

[42] Modeling Hydrology and Plant Growth in Dryland Agriculture

Dry farming was an important practice during prehistory and continues to be vital for small-scale farmers
in many areas of the world today. Archaeologists have modeled factors affecting crop productivity to get
at population size and growth, as well as societal collapse. It is acknowledged in studies of modern and
prehistoric contexts that water is the most important limiting factor for plant production. Archaeological
research on the relationship between water and plant growth has focused mainly on precipitation and
surface water. However, contemporary agricultural hydrologists model water movement horizontally
across space and vertically within a profile, which are also important factors for understanding long-term
patterns in crop production. We are developing a model that incorporates hydrological processes across
all three spatial dimensions to provide a more accurate portrayal of water availability, which is then
related to plant growth so that we can determine the conditions for crop failure. The research is being conducted in the Mesa Verde region of the American Southwest.

Nair, Stella (University of California, Los Angeles)

Extraordinary Spaces: Thupa' Inka and the Architecture of Royal Theater

For the Inca, architectural gestures were used to choreograph movement on both the large and small scale. Because of this, architectural remains provide critical evidence into the rituals and processions that once took place on Inca installations. This paper examines this material evidence in order to expose the complex spatial practices that defined rituals at a royal estate. These architectural gestures unmask the diverse players who participated in events and the distinct landscape features that were connected to the public stage. In addition, the evidence reveals the ways in which processional space changed when activities shifted from the public to the private.

Change in Patterns of Cultural Interaction in the Early State Formation in Japan

This paper discusses temporal change in patterns of interactions with China and the Korean peninsula from the third to fifth centuries A.D. Before the fifth century, the dominant pattern of foreign interaction was of the “goods importation type,” i.e. to import material culture of advanced technology. In the fifth century, a new pattern of foreign interaction, named “technology adoption type,” became dominant. Korean specialist craftsmen, invited to settle in Japan, introduced new technologies. This shift strengthened the power of the central polity considerably. Before the fifth century, imported Chinese bronze mirrors were a symbol of authority. As it became difficult to import Chinese bronze objects in the fourth century due to the unstable political situations in East Asia, the central polity of Yamato sought for new material symbols of their authority. Such material symbols included stoneware fired in kilns at temperature above 1000 degrees and new types of iron tools, both made in Japan by Korean specialists. The central polity widely distributed these new material cultures to local regions, which contributed to the maintenance of the central power.

Agricultural Strategies and Long-Term Soil Fertility in the Southern Peruvian Andes

This study, part of the PIACI archaeological project, focuses on bulk soil fertility analyses of targeted samples from excavated profiles of a terrace system at the SAN1 Chocorvos-Inka-Colonial settlement site, near modern-day San Francisco de Sangayoico, along the Olaya highland tributary of the Ica River, in the Southern Peruvian Andes. Andean agriculturalists face a variety of challenges including seasonal water availability, steep slopes, variable soil depth and quality, and wide diurnal temperature fluctuations. The use of agricultural terracing in the Andes is evident wherever agriculturalists have turned to intensification in order to mitigate the effects of erosion related to slope cultivation. Such erosion leads to the loss of the mineral and organic- material rich A-horizon, and, in cases where erosion occurs faster than pedogenesis, exposes lower, non-arable soils leached of organic material. Given the regional and local-site chronology (AD 1000-1615), the terrace systems of SAN1 provides an ideal location to test how short-term adaptation of agricultural techniques (e.g., construction format, seasonal burning, fertilizer use, etc.) have affected long-term soil fertility. Also, by looking at the effects of terraced-land management strategies on soil fertility, over the Longue Duree, conclusions can lead to a more resilient approach to modern highland farming.

Among the Outsiders? Past, Present and (Uncertain) Future of the Coastal Cilliní of Western Ireland

The cillín—a burial ground for unbaptized infants, suicides, and others considered unsuitable for interment in consecrated ground—is a commonplace and often completely inconspicuous feature of the Irish littoral archaeological landscape, yet it is this very lack of notability that may herald the
disappearance of the sites in the face of today’s ever-increasing coastal change. Though much referenced in place-names and recently recognized as holy ground by the Catholic Church, comprehension of the role of the seaside cillín in its original context is lacking, as is a much-needed archaeological focus on a comprehensive plan for the continued existence of these at-risk sites. This poster will investigate the unique connection to the overseas Otherworld of those cillíní located along the island’s western shoreline as well as their significance in contemporary Ireland and will examine possible methods of preservation, balancing the desire for understanding of prehistoric and historic treatment of “the other” with the need for long-term site protection and the status of cillíní as sensitive and sanctified sites.

Comparative Attribute Analysis of Stone Tools from Tabun Cave

The goal of this study was to determine if Amuidan blades from Tabun Cave, collected by Dorothy Garrod, are typologically and technologically comparable to Amuidan blades collected by A. J. Jelinek. The blades in this study were analyzed using the same attribute analysis from a previous study performed on Jelinek’s blades in order to control for diacritical comparisons between the two assemblages. Attribute analysis was used in order to situate the blades into a chaîne opératoire in order to attain a conceptual and analytical perspective of the reduction sequence from the point of view of the agents who produced them. The comparisons resulted in similar numbers, indicating that the blades collected by Jelinek are Amuidan based on their metric resemblance to the blades collected by Garrod. These characteristics include: thick, naturally backed, lateralized/débordant blades with prepared platforms and simple dorsal scar patterns. Based on the success of these diacritical attribute analyses, it is suggested that these qualitative and quantitative measurements be used as a preferred set of attribute characteristics for identifying Amuidan blades in future analyses.

Provenancing of Silcrete Artifacts: New Insights into Middle Stone Age Human Behavior from Northwest Botswana

Recent research on lithic artifacts from the MSA layers of White Paintings Shelter (WPS; Tsodilo Hills, Botswana) has demonstrated that early humans chose to transport silcrete for tool-making to the site from Lake Ngami and the Boteti River, more than 220km distant. Here, we apply our geochemical provenancing approach to silcrete artifacts from the three remaining major excavated sites with MSA deposits in Botswana: Corner and Rhino Cave (Tsodilo Hills) and :#Gi (an open-air site near the Botswana/Namibia border). Results for Corner Cave are similar to WPS, with 23 of 26 sampled artifacts matching the chemical signature of outcrops at Lake Ngami and the Boteti. One sample was acquired from an outcrop on the Okavango River and two are from unknown locations. Results from Rhino Cave are different and indicate that silcrete used at the site was sourced almost exclusively from the Boteti; one sample of 18 matched the chemical signature of outcrops at Lake Ngami and two were from unknown locations. At the time of writing this abstract, results from :#Gi were incomplete. We discuss our findings with respect to arguments about human mobility during the MSA, and in relation to the likely use patterns at the three sites.

Nash, Carole (Geographic Science, James Madison University)

Thinking like an Archaeologist: Undergraduate Experiential Learning in a Blue Ridge Compliance Setting

Archaeology has much to offer undergraduate education: its interdisciplinary approach; its focus on temporal and spatial cognition; and its emphasis on a broad skill-set oriented to the field sciences. Archaeologists who teach undergraduates commonly offer anecdotal evidence of the transformative power of the experiential pedagogies that are hallmarks of archaeological training, but our contributions to the scholarship of teaching and learning (SoTL) are limited. Falling under the rubric of active learning, experiential pedagogies encourage students to reflect on the learning process through ‘doing.’ Well-assessed and shown to encourage a higher level of understanding and integration for students and teachers alike, experiential learning results in the mastery of transferrable skills so sought after in undergraduate education. The application of foundational knowledge and technique in the field setting is presented here through a case study from a decade-long research program in Shenandoah National
Park, where undergraduate students engaged in archaeological field schools and short-term surveys continue to receive training. Responsible not only for the college credit but also professional-level work that meets the Secretary of Interior and SHPO standards, the students’ assessments included contributions to CRM reports and conference papers.

Nash, Donna (UNCG)

[203] House Burials or Buying Houses: Elite Wari Mortuary Practices at Cerro Baúl, Peru

The Wari (600-1000 CE) practice of smashing pottery as a form of ritual is well documented, however such depositions occur in a number of different contexts that may indicate that pot smashing was a component of several different types of ceremonies. Prominent among them is the association of pot smashes with residential burials. The tradition of residential burial in the Andes dates back to the Preclassic period, however burials in caves and cemeteries were also present among Wari affiliated groups. In this paper I describe patterns of pot smashing that correspond with residential burials and house abandonment to examine mortuary ritual at the Wari provincial center of Cerro Baúl in the southern sierra of Peru. Current data suggests a link between funerary events and closure rites and I compare the case of Cerro Baúl with other Wari affiliated sites to address this important connection and explore both its sociopolitical implications and potential symbolic meaning.

Nash, Robert (Montgomery Archaeological Consultants)

The hypothesized Numic expansion into the eastern Great Basin remains a popular explanation for abandonment of Fremont lifeways. This study tests the notion of a population replacement in Utah Valley at about A.D. 1300 during the Promontory Phase through statistical analysis of side-notched arrow points. The expectation is that there should be measurable differences among arrow point types if a population replacement occurred. Results of the analysis not only support a population replacement ~A.D. 1300 but also suggest a population replacement occurred after the Promontory Period.

[231] Placing Seventeenth Century Lakota and Dakota villages in Northern Minnesota: A Close Examination of Guillaume Delisle’s 1697 Map of the upper Mississippi

In 1697 the French cartographer Guillaume Delisle produced a map of the upper Mississippi River system based upon the notes of the explorer Le Sueur. The locations of 22 contemporary Siouan villages are noted upon this map. This paper presents the results of an attempt to locate these villages using modern spatial references. The features on Delisle’s seventeenth century map are cross referenced, broken down and reassembled based upon other historic maps of the Minnesota region. The results of this project suggest an accurate representation of Lakota and Dakota territories at the cusp of the fur trapping era. A further stage of the project attempts to correlate the results of historic research with the archaeological record.

Natoli, Amelia (Statistical Research), Cannon S. Daughtrey (University of Arizona), Rita Sulkosky (Statistical Research, Inc.), Z. Nahide Aydin (Statistical Research, Inc.) and Jesse A.M. Ballenger (University of Arizona)

From 2010 to 2013, Statistical Research, Inc. conducted excavations at Site AZ T:7:419 (ASM) for the Luke Solar-Power-Array Archaeological Data Recovery Project. Totaling about 3000 features spread across 44 acres, this is the largest Archaic site identified in the greater Phoenix Basin. The site is located on the lower-bajada of the White Tank Mountains near Phoenix, Arizona. Radiocarbon dates range from the Early Archaic to the Classic Period (ca. 7000 cal. B.C. – cal. A.D. 1200), with the most intensive occupation during the Middle to Late Archaic periods (ca. 3300–700 cal. B.C.). Over 2000 ground stone artifacts were recovered from the site, and nearly a third of those were found in an extramural context, believed to have been strategically cached or left in-place for future processing activities. Most of the extramural ground stone are represented by complete, formally shaped tools. In this study, we examine how the spatial and temporal distribution of various ground stone artifacts informs on the organization of
wild plant processing before and after the appearance of maize in the U.S. Southwest, whether caching behavior can be identified at the site, and the evidence for task-specific tool associations (tool kits).

Naudinot, Nicolas (University of Nice)

[201] Environment Changes and Socio-economic Transformations in Western Europe during the Second Half of the Late Glacial: Confrontation of the Azilian/Post-Azilian and Epigravettian Techno-Complexes

During the LGM, Europe starts being split in two main large cultural entities: the Epigravettian complex and the Western Europe sequence. In this paper, we focus on the end of the Upper Palaeolithic and more precisely on the period between the Allerød and the beginning of the Holocene. This period is particularly marked by several climatic changes and is thus a perfect "laboratory" to study the interactions between societies and paleoenvironment. Our paper essentially focuses on lithics. This material allows to study the socio-economic system of a society by analyzing an assemblage in a global perspective looking at all the elements of the chaine opératoire from the raw material procurement to the use and management of the tools, passing by the objectives and methods of production. We will explore the impacts of climate changes and especially the Younger Dryas event on the various environments of our research area (Atlantic and Mediterranean areas). Thanks to an active research in Western Europe these last years and a second wind in the study of the Epigravettian, it is possible to compare the responses of these two larges entities to the different environmental changes from the Allerød warming to the beginning of the Holocene.

[290] Rethinking Conclusions from Large Housepits in the Interior Pacific Northwest

In the interior Pacific Northwest, large housepits are often equated with complex social organization defined by affluent ownership or control over resource bases and their surpluses. As a result of excavating almost the entire floor of a housepit measuring 23 meters in diameter at the Slocan Narrows Pithouse Village, we suggest that this premise needs to be reexamined. The housepit dates to 2,750 cal BP, and apart from its size, the excavations yielded no material remains that are the hallmarks of an elite status house. However, it could be argued that the social mechanisms that held a large population together to build and use this house in an egalitarian manner were certainly complex. As we move into a 21st century of Pacific Northwest archaeology, several of the long held assumptions regarding house size as well as the notion of complex hunter-gatherers will need to be reexamined.

[316] The Isthmus of Santa Catalina Island: Archaeology Reexamined through Historic and Modern Maps

For years, extensive archaeological research has been conducted on the Santa Catalina Island isthmus, with a number of important prehistoric and historic sites having been identified. Here, I present maps showing archaeological research that has been conducted over the years overlaid with maps of newly recorded archaeological sites on, and near, the isthmus. Using Trimble GPS survey and ArcGIS software, I compared different maps and layers, showing how sites have changed spatially and temporally through time as a result of various cultural and natural phenomena.

[312] Royal Ritual and Public Memory at the City Shrine of Ancient El Peru-Waka’: The Archaeology of Burial 61
During the 2012 field season at El Peru-Waka’, archaeologists discovered a royal Maya burial in the fronting platform of the city’s main civic-ceremonial shrine. A small alabaster jar in the chamber featured hieroglyphic texts which name its owner as Lady Waterlily Hand. This is another way of referencing Waka’s Royal Queen Lady K’abel who married K’inich Bahlam II. She also carried the title Kaloomte’ or “supreme warrior” and is most famously featured on Waka’s Stela 34 which dates to 692 AD and housed in the Cleveland Museum of Art. Preliminary analyses indicate the skeleton is middle- to-old aged. Poor preservation and ambiguous traits rendered definitive sexing of the individual impossible, though the robusticity of the remains is consistent with depictions of this warrior queen. Moreover, we argue the associated artifacts not only support a seventh-century date for the interment but also cultural affiliations with the kingdom of Calakmul, the place of Lady K’abel’s origins. Previous research demonstrates the enduring ritual engagement by 8th and 9th century Wakeños of this building. Determining this was the final resting place of an important royal figure therefore strengthens our understanding of how Wakeños performed social memory.

Nealís, Stuart (University of Kentucky) and Barry Kidder (University of Kentucky) [264] A Multi-stage Geoarchaeological Analysis of an Undocumented Mound in Greenup, County, Kentucky

We present the results of some preliminary fieldwork conducted on a 6m tall mound located on Raccoon Creek, a tributary of the Little Sandy River in Greenup County, Kentucky. Gradiometric survey in the field surrounding the mound shows areas of potential feature locations for future fieldwork. Solid core and bucket auger samples were collected from four locations on and off the mound to determine construction sequence and potential cultural affiliation. Samples were subjected to particle size analysis, chemical characterization, magnetic susceptibility, and XRF testing. Results show that mound fill material was from surrounding hill slopes rather than the floodplain in which the mound stands, and that at least one buried A horizon is present. One piece of wood charcoal was collected from a core suspected to be near the edge of the original mound slope, returning a date of 600 BP. Another charcoal sample from the opposite side of the mound has been sent out for AMS dating and will be presented with the rest of our data in determining the construction sequence and timing of this large earthen mound. Ultimately, we believe using multiple geoarchaeological techniques can help source sediment origins and address the sociality of mound construction.

Neeley, Michael (Montana State University) [71] Changing Settlement Organization in the Late Pleistocene of the Southern Levant

Archaeologists have long recognized variation in settlement organization among hunter-gatherer societies. Typically, this has involved differentiating between patterns of residential based mobility and logistical organization using variables such as site size or artifact density. While these variables result in an impressionistic understanding of prehistoric settlement organization, a standardized approach advocated by Riel-Salvatore and Barton has the potential to separate the different elements of settlement behavior. A key component of their research is the distinction between curated and expedient technologies. In this paper, their approach is applied to selected lithic assemblages from the Late Pleistocene (Upper Paleolithic, Epipaleolithic, and Natufian) of the southern Levant. Traditional interpretations for these periods, spanning from 40,000-10,000 years ago, have emphasized residential based mobility for the Upper Paleolithic and Epipaleolithic with higher levels of logistical organization for the Natufian. An initial assessment of pattern indicates greater than expected internal variability in settlement organization within the different time ranges. The examination of late Pleistocene settlement trajectories provides greater understanding of different land-use strategies in the context of changing resource and environmental conditions.

[91]  New Light on the Prehistoric Purrón Dam Complex: Small Corporate Group Collaboration in the Tehuacán Valley, Puebla, México

Recent survey and test excavations at the Purrón Dam Complex (PDC) in the Barranca Lencho Diego in the Tehuacán Valley of Southern Puebla, México, demonstrate the value of resurveying previously studied areas. Additional habitation sites and water management features, a cave with pictographs, and a major canal were discovered, increasing the number of recorded sites from six to forty-four. Ceramic chronologies and the synthesis of twelve chronometric dates suggest that water management was initiated in the barranca by the Early Formative period at ca. 1100 B.C., and perhaps earlier, and that the Purrón Dam was completed and had its highest population levels by the Middle to Late Formative (ca. 650-150 B.C.), a time when settlements were small and decentralized. This challenges existing interpretations placing the PDC florescence during the Early Classic period (ca. 150 B.C. – A.D. 250), a time period with larger aggregated communities displaying clear signs of social ranking, and greater inter-regional interaction. The results have implications for understanding the causal links between political complexity and agricultural intensification, and support recent ethnographic and archaeological research discrediting the argument that increasing social complexity leads to the construction of large water management systems.

[250]  Prehistoric Industries of the Mangrove Zone of eastern Soconosco, Pacific Coastal Chiapas, Mexico

Recent fieldwork in the mangrove zone of far-southern Chiapas, Mexico has included site identification via LiDAR, surface and subsurface testing, and sediment coring in off-site locations. Goals of the work are to understand how humans used the estuary zone at different times in the past and to generate a record of variation in the intensity of those activities. Pollen and charcoal from dated sediment cores provide a record of landscape changes that complements the evidence of archeological site density. Data generated so far indicate steady, uninterrupted growth during the Formative period together with a trend toward increasingly specialized production of salt, presumably for consumers at Izapa and other coastal plain and piedmont sites. This period of growth was truncated around AD 200, roughly coincident with the cessation of monument carving and a probable demographic collapse at Izapa. The zone was abandoned for 500 - 600 years, after which Terminal Classic Plumbate potters re-occupied many of the Formative period mounds.

[232]  Archaeological Evidence for Increasing Inequality within a Slave Settlement at Monticello in the Late 18th Century

This poster summarizes recent archaeological research into among-household variation at Site 8, a domestic site occupied by enslaved field laborers at Thomas Jefferson's Monticello plantation during the last quarter of the eighteenth century. Correspondence analysis of plow zone ceramic distributions reveals the existence of at least two residential groups and increase over time in the distance between them. Ceramics and architectural evidence indicate a more important role for storage and higher levels of conspicuous consumption among the northern group. Spatial patterns in artifact size indicate greater investments in yard maintenance for the north group as well.

[247]  Embodied Identities in the Prehistoric Southwest

This paper summarizes the results of a collaborative research project on how the identities of prehistoric Southwesterners were encoded in various aspects of their appearance. Morphological features, clothing, jewelry, facial decorations, and hair styles conveyed information about a person’s gender, status, other social roles, cultural affiliation, religious beliefs, heritage, and inter-group connections. The archaeological record documents tremendous variation for each of these appearance characteristics both within and between cultural groups. While we tend to analyze these identity markers individually, that is not how they would have been perceived in their living contexts. Rather, a prehistoric Southwesterner would have seen the various aspects of a person’s appearance all together as a composite image. Thus, conclusions
about the person’s various identities would have been drawn from multiple lines of evidence with the most visible and redundant messages having the greatest importance on that particular occasion. In this paper, we present composite images for several cultural groups and discuss the identity messages that these images conveyed.

Neivens, Mary [61] see Neivens De Estrada, Nina

Neivens De Estrada, Nina (Tulane University) and Mary Neivens (Holmul Archaeological Project) [61] The First Maya Ceramics, and the Mother-Daughter Team Who Glue Them Together
In this paper we will share our experiences with Norman Hammond as a mentor and friend. Mary Neivens was a young scholar in Belize in the 1970s when she met Norman and began a lifelong friendship. Our journey continued in 2000 when Nina Neivens began studies on the Maya at Cuello. Norman has influenced our continued studies in Guatemala where we have researched the earliest Maya ceramics from Holmul and Tikal. This research has led to a re-evaluation of the interaction between early Maya villages and their connections to other Mesoamerican societies.

Nelson, Elizabeth (University of North Texas Health Science Center, Dept. Physiology and Anatomy) and Christine Halling (University of Indianapolis) [12] Evidence for Skeletal Fluorosis at the Ray Site: a Pathological Assessment and Description of Community Health
In environments with naturally high or anthropogenically increased fluoride levels (>1.5mg/l), communities are at risk for toxic exposure to fluoride. Groups exposed to toxic levels of fluoride have higher incidence of maladies of the musculoskeletal, reproductive, and neurological systems. Individuals who experience continuous exposure will develop skeletal fluorosis, a condition characterized by hypersclerotic activity evidenced by the ossification of ligamentous and tendinous attachments, along with an increased incidence of fractures. Older adults are more commonly affected than younger individuals, and men more frequently than women. Archaeologically, skeletal fluorosis has been reported in Bahrain, Naples, and the UAE, but not in the Americas. In this study we evaluate the prevalence of symptoms consistent with skeletal fluorosis at the Ray Site, a Middle Woodland site in the Illinois River Valley with geologic conditions conducive to uptake of toxic levels of fluoride. Of the 117 individuals analyzed from the Ray Site, 12 display characteristics consistent with skeletal fluorosis. We describe sex differences in manifestation of skeletal fluorosis, possible implications for community health, and plans for future studies.

Nelson, Ben (Arizona State University) [66] Connectivity of Social Change in Mimbres and Points South
The work of the Mimbres Foundation showed that in comparison to earlier and later populations in the Mogollon region, the Classic Mimbres experienced anomalous population growth, aggregation, agricultural intensification, and artisanal production. Archaeologists interested in understanding these prehispanic changes in a wider framework have demonstrated connections and parallels to groups to the north and west, especially with Chaco Canyon and the Hohokam but also to a lesser extent Paquimé. Scholars have shown that these regional histories are related in some ways, based on both material connections and synchronicities of growth and reorganization. In this paper we extend these explorations to the south, particularly to the regions on either side of the Sierra Madre Occidental. What connects Classic Mimbres with Mesoamerica? Is Classic Mimbres part of a synchronous rise of polities in neighboring regions to the south, or does its development adhere more closely to US Southwestern temporal pattern? By reviewing evidence of connectivity with these southern regions we outline what is known and what remains to be learned if we are to understand the place of the Classic Mimbres development in a macroregional framework.

[66]  **Mimbres Continuity and Change**  
Through his Mimbres Foundation research program, Steven LeBlanc mentored a generation of Southwest archaeologists, insisting that we think beyond popular perspectives. He challenged us to create new ideas and to evaluate those ideas with careful fieldwork and analysis. One of the big research questions of the 1970s in the Southwest was “what happened to the Mimbres people.” In this paper we reframe that question in terms of continuity and change in the Mimbres tradition through the 12th century. Challenging earlier explanations of abandonment and disappearance, we document the reorganization of people who created new traditions and reshaped their social landscape while remaining in the Mimbres region. This research builds on the strong contributions of LeBlanc without which these new understandings of the past would not be possible.

[23]  **The Use of High-Altitude Environments in the Southern Andes**  
The southern Andes between 34° and 35° SL are one of the highest mountainous regions in the Americas. Their highly seasonal variability increase with the altitude, diminishing their biomass productivity and those places apt for human occupation. In this paper we present archaeological data about human adaptations developed to exploit and lived in environments located above 3000 meters. The results show a strong focus on big game hunting, associated with the consumption of non-local vegetal resources. Subsistence and mobility are discussed in order to understand the importance of these high elevation sites in regional context.

[129]  **Tupinambá Practices of Warfare, Revenge, and Cannibalism in 16th Century Brazil**  
The Tupinambá were semi-sedentary agriculturalists inhabiting the Eastern Coast of Brazil. Sixteenth-century European explorer accounts offer rich details of Tupinambá life and warfare practices, suggesting the presence of a highly organized violence and warfare system embedded in their daily practices, animistic and cosmological beliefs, celebrations, exo-cannibalism, and in their ideals of honor, prestige, and revenge. Building on ethnohistoric information, this paper also discusses the potential to further our understanding of Tupinambá warfare practices through study of material culture signatures. Because Tupinambá archaeology is still in its infancy, we attempt to correlate the ethnohistoric information with the types of objects and features associated with violence that archaeologists could reasonably expect to recover, should the accounts be accurate and the materials preserved. We argue that by using such analogies as a starting point, future researchers will be able to better test their hypotheses against the archaeological record in efforts to augment knowledge about Tupinambá lifeways.

A Quarter Century of Training Undergraduate Archaeologists at IUP

Since 1989, when the Archaeology Track of our major was instituted, IUP archaeologists have been teaching our undergraduates about archaeology. While solidly grounding their study in four-field anthropology, our students emphasize hands-on experiences in the field and in the laboratory. Both an archaeological field school and an introduction to CRM archaeology are requirements for our Archaeology Track. Another requirement is a laboratory methods class, and many of our students have gained solid experience in the curation of artifacts through working for IUP Archaeological Services. We also encourage students to pursue internships and to participate in professional meetings while still undergraduates. The combination of academic study in anthropology and practical experiences has worked well both for graduates who go into the CRM industry as field technicians and for graduates who immediately pursue graduate work.

Neusius, Phillip (Indiana University of PA), Ben Ford (Indiana Univ. of PA), Sarah Neusius (Indiana Univ. of PA) and Beverly Chiarulli (Indiana Univ. of PA)

Meeting the Needs of a Modern Archaeology Workforce

The IUP Anthropology Department's MA in Applied Archaeology Program and undergraduate archaeology track are focused on providing students with the skills necessary to become practicing archaeologists prepared to work as professionals in cultural resource management and related heritage fields. Both programs were designed with unique components to distinguish them from more general graduate and undergraduate anthropology degrees, yet still provide a broad enough background to insure their ability to deal with a variety of issues facing CRM today and in the future. Training is provided in both the basic skills necessary for doing archaeology and the latest technologies and methods within a developing discipline. Both programs also focus on developing writing and critical thinking skills through both writing intensive courses and seminars such as Cultural Resource Management, Laws and Ethics and Issues in Historic Preservation. Students are encouraged to work collaboratively with their peers, participate in both professional and amateur societies, and seek opportunities to work with private companies as well government agencies even before graduating. Our use of a professional advisory board helps with keeping curriculum up to date and providing a model of professionalism for our students.

Neves, Eduardo (University of São Paulo)

Formal Stability and Technological Variation at the Polychrome Tradition of Western Amazonia

The Amazon Polychrome Tradition was defined in 1961. It comprises diversified vessel forms including anthropomorphic urns and plates decorated with polychrome painting on red, black, yellow and white, and modeling, incision and excision. The distribution of sites with polychrome ware, ca. 900 to 1600 AD, from the mouth of the Amazon to the foothills on the Andes, led to an early hypothesis that it reflected an expansion of people from the Andes eastwards to the lowlands. Recent research shows that polychrome sites or occupations are earlier in the east than in the west, in a spread that lasted a few centuries which was associated with conflict, as seen by the construction of defensive structures on sites with previous occupations. This paper brings contextual and ceramic data to show that, although made with a rigid formal code, the technology of polychrome vessels varied in paste in samples from sites distributed along a 500 km stretch in the Central Amazon basin. This pattern suggests that the rigid grammar of formal and decorative patterning of ostentatiously decorated pots was structured to define the identity of pottery makers in a context of expansion associated with warfare into previously occupied areas.

Comparing Compositional Data Acquired by pXRF and LA-ICP-MS for Cherts in Eastern Nevada

Current models of Paleoindian lithic technological organization, mobility, and exchange in the North American Great Basin rely heavily on the provenance and technological analysis of obsidian and fine-grained volcanic (FGVs, e.g., andesite) artifacts, yet chert dominates many sites in the region. Here I present a comparative analysis of compositional data obtained using portable x-ray fluorescence
spectrometry (pXRF) and laser ablation inductively-coupled plasma mass spectrometry (LA-ICP-MS) for several chert sources in eastern Nevada. Analysis of the compositional data acquired by these methods reveals comparable patterning that can be used to discriminate the chert sources. In turn, these data can be used to source chert artifacts in the region, ultimately building toward a model of Paleoindian lithic technological organization, mobility, and exchange that includes obsidian, FGVs, and cherts.

Newman, Elizabeth (Stony Brook University) and Karime Castillo Cárdenas (Independent Researcher)

Cultural Continuity and Adaptation in Nineteenth-Century Ceramics in Atlixco, Mexico

Excavations in the worker’s quarters, or calpanería, of the Hacienda San Miguel Acocotla yielded a large ceramic collection dating primarily to the nineteenth century. The range of ceramic forms and types used by workers at Acocotla suggests continuity of certain Prehispanic ceramic traditions as late as the last decades of the nineteenth century, as well as the adaptation of local production to European technologies and preferences. This paper will provide an overview of the entire assemblage and will highlight a locally produced ceramic whose paste strongly resembles the Classic type known as Anaranjado Delgado Burdo, but whose form is that of a typical European vessel. The ceramic assemblage from the Hacienda Acocotla offers an opportunity to explore the degree to which traditional indigenous lifeways were (and were not) impacted when workers became residents at the Hacienda Acocotla.

Newman, Sarah (Brown University)

Game, Prize, and Player: Deer Hunting among the Classic Maya

Bloodshed was an essential element of rulership among the Classic Maya. Whether through scenes of self-inflicted sacrificial wounds, the ritual battles of the ballgame, or brutal recreations of captive-taking and outright warfare, the king as victor was a common motif. It comes as no surprise, then, that the violent sport of the hunt held special meaning for members of ancient Maya royal courts. Hunting, especially deer hunting, served to recreate mythic events and engage supernatural beings. Not just a metaphorical conquest, the hunt also played an important role as a very real training ground for the bloodier, riskier battles of actual warfare with caught, bound, and butchered deer often equated with human captives. Moreover, depictions of deer with women in both lascivious and maternal contexts reveal further underlying associations of the hunt with sexual dominance and the taming of the wild.

Management and Research of US Navy Sunken Military Craft by Naval History & Heritage Command

The US Navy is responsible for approximately 3,000 shipwrecks and 14,000 sunken aircraft. These are distributed worldwide and located in territorial, foreign, and international waters. Ranging in age from the ships of the Continental Navy to the present, the largest numbers are from the American Civil War and World War II. They are protected under US laws such as the Sunken Military Craft Act and National Historic Preservation Act, but also international principles of maritime law in regards to principles of sovereign immunity. Naval History and Heritage Command manages these wrecks for DoN in order to preserve and interpret the Navy's history. Considerations include archaeological research potential, recreational diving access, war graves, and environmental hazards, which can include ordnance and fuel oils. This paper discusses these broad issues as well as some specific archaeological investigations.

Ngandali, Yolona (University of Wisconsin La Crosse - McNair Scholars)

Public Archaeology: Visualizing Wisconsin’s Prehistory with Digital Media

Relevance and accessibility to the public are key issues in archaeology that need attention and applied practical applications. Sharing information via Internet through interactive website design can bridge the gap between archaeologists and people outside the profession. In this project technical data results are transformed into interactive elements to produce educational and public-friendly web content. Visual media can encourage the public to find a connection to the past that drives the way they think about the future. The web content is based on archaeological excavations and laboratory analyses conducted in the
Upper Mississippi Valley. Established evidence about the function of sites, the range of tool production activities, subsistence activities, and evidence of trade from other regions are incorporated into a comprehensive digital exploration of the daily life of Wisconsin's prehistoric farmers. The website will showcase the archaeological methods from excavation to analysis emphasizing the interactions of culture and environment with text, 360° images, maps, interactive diagrams, 3d visualization tools, and animated video. Interactive digital media promotes public interest, participation, and comprehension of archaeological concepts. Incorporating social media and feedback options will instigate communicative discussions and build a stronger dialogue between archaeologists and the community.

Nichols, Kristi Miller (UTSA-Center for Archaeological Research) [169] Excavations Associated with the Stabilization of the Church at Mission San Juan de Capistrano, San Antonio, Bexar County, Texas
Archaeological investigations occurred at Mission San Juan de Capistrano in San Antonio, Texas in association with the stabilization and underpinning of the church’s walls. Due to the potential for collapse, the church walls needed to be reinforced. To assist with the stabilization, CAR archaeologists excavated test units around the exterior of the church walls. Later, the removal of matrix around the base of the church was monitored and approximately 50% of the soil was screened for artifact collection. The artifact assemblages collected during the excavation and matrix removal consisted of Spanish Colonial and 19 Century material. High densities of glass, ceramics, and faunal remains were collected. In addition to the cultural material deposits encountered, burials were uncovered along the eastern wall of the church under the bell tower. All burials were removed and later re-interred at a location within the walls of the mission compound prior to the end of the project.

Nichols, Deborah (Dartmouth College), Wes Stoner (Missouri) and Destiny Crider (Luther College) [275] A Geospatial Approach to the Development of Postclassic Markets: Ceramic Production and Exchange
Dan Healan’s research has significantly advanced understanding Postclassic obsidian manufacturing and exchange in highland Mexico. In the late 1980s he assisted excavating an obsidian core-blade workshop at Otumba, an Aztec city-state capital and manufacturing and commercial center. Complementing studies of obsidian production and trade, we employ a newly developed geodatabase of ceramic chemical data to apply a spatial perspective on the development of market systems in the Basin of Mexico through time from the Epiclassic through Late Postclassic period.

Nicodemus, Amy (University of Michigan) and Ashley Lemke (University of Michigan) [300] From the Bronze to Iron Age: Diachronic Faunal Investigations at Pecica Șantul Mare, Romania
Pecica Șantul Mare, a large tell in western Romania, has a complex archaeological sequence dating from the Early Bronze Age to the Iron Age. New investigations reveal Pecica to be a complex center of Bronze Age trade and craft production with striking social differentiation. In addition to the large assemblage of ceramic and metallurgical remains, animal bones are well preserved in fill layers, domestic contexts, and various features. This paper presents the results of faunal analysis across the Bronze and Iron Age occupation at Pecica and demonstrates that the use of animals for subsistence, secondary products, and trade changed remarkably through time, although the species remain largely consistent. In addition, a detailed analysis of cutmarks is used to demonstrate how food preparation and butchering behavior changed in the context of evolving technology.

Nicolaides Ramsey, Monica (University of Texas at Austin), Monica Nicolaides Ramsey (University of Texas at Austin) and Arlene Rosen (University of Texas at Austin) [236] Wedded to Wetlands: Exploring Late Pleistocene Plant-Use in the Eastern Levant
The mosaic ecology of the Late Pleistocene Levant has been referred to by many authors investigating Epipaleolithic use of wild cereals as a prelude to cultivation, but until recently it has rarely been the focus
of studies investigating hunter-gatherer adaptations and diverse wild plant collection strategies. Partly, this was due to poor preservation of macro-botanical remains at Epipaleolithic sites with the exception of Ohalo II. Our analyses of phytoliths from sites in the eastern Levant, compared with phytoliths from Ohalo II, reveal evidence for how foragers used the highly diverse ecological zones in these regions. Abundant phytoliths from reeds and sedges indicate the critical importance of wetlands in hunter-gatherer subsistence strategies, especially during arid phases. Wild cereals and small-seeded grasses point to steppe and parkland exploitation, and woody plants indicate use of woodlands. From the LGM through the Early Holocene, wetland, steppe and woodland zones formed an integrated resilient system of plant-use, with wetlands providing an especially important focal point. The option of tethering subsistence foci to reliable wetland zones provided a dependable natural food-storage repository and may have allowed greater risk-taking strategies for other types of plant and animal exploitation beyond the wetland zones.

Nielsen, Axel (CONICET Argentina) [27] The Destruction of South Andean Plazas at the Time of Inca Expansion
The Late Intermediate Period (1200-1450 CE) was a time of population aggregation and supra-community political integration throughout the Southern Andes (SW Bolivia, N Chile, and NW Argentina). Many of the large residential conglomerates that formed during this period show clearly defined plazas, frequently associated with representations of ancestors (chullpas, towers, monoliths) which attest to the central role played by genealogy and collective memory in the reproduction of the social order of the time. Research conducted during the past three decades in several of these public spaces has revealed their violent destruction during the 15th century, a phenomenon that correlates with the introduction of Inca material culture and with significant changes in regional landscapes, including rapid site abandonment and community relocation, the establishment of imperial centers and landmarks organized according to different cosmological principles and vast projects of agricultural reclamation and mining. Combining data from different regions we outline some of the principles of this domination strategy developed by the Incas in the Southern Andes, a strategy that, by manipulating plazas and other public settings, transformed local memories and established new principles of political legitimacy.

Nielsen, Jesper (University of Copenhagen) and Toke Reunert [33] The View from Chalcatzingo: Studying Mesoamerican Iconography in Natural Settings
While researchers working with Palaeolithic cave art and rock art in Europe have long recognized the importance of specific location and context of the imagery, there is still a tendency in Mesoamerica to focus mainly on the motives and regard cave walls or cliffs merely as "pages" made available by nature. In this paper, we discuss the need to integrate the surrounding landscape, sightlines, and specific features of the cliff/wall in any kind of iconographic analysis and interpretation. In this paper we focus on two Middle Preclassic sites in central Mexico, Chalcatzingo and Oxtotitlan, both of which offers excellent examples of the meaningful interplay between natural features and various iconographic representations. Additional sites and monuments we consider are the Xoc cliff carving in Chiapas, the stela from the Nevada de Toluca and the newly discovered Condoy Cave in Oaxaca. To understand these and similar examples of elite Mesoamerican iconography situated outside an architectural context, an "arm chair" art historical approach will rarely suffice, and we thus encourage iconographers to do more "boots"-on fieldwork - much in line with the work of Jim Brady.

Niespolo, Elizabeth (CSU Long Beach), Gregory Holk (CSU Long Beach), Neff Hector (CSU Long Beach) and Brigitte Kovacevich (Southern Methodist University) [140] Using Stable Isotopes to Link Maya Jade Artifacts and Geologic Sources in the Motagua Valley, Guatemala: A Refined Method to Determine Artifact Provenance
The only known jadeitite source region in Central America lies along the Motagua River in Guatemala.
Beads from north of the Motagua Fault Zone (MFZ) differ petrologically from those found south of the MFZ; thin section petrography reveals three populations of differing mineralogy south of the MFZ. However, petrologic multiplicity of jadeite within each source region makes the identification of artifact provenance difficult using current methods. Since northern and southern occurrences of jadeite formed in distinct petrogenetic environments, stable isotopes may improve the resolution of provenance determination over that possible with mineralogy alone. The present study uses stable isotopes (O and H), together with other petrologic and geochemical analyses, to address the problem of discriminating jade sources near the MFZ. The utility of this approach is evaluated with jade debris from Cancun, the southwestern Classic Maya site on the Pasión River, north of the MFZ. Since the Cancun workshop may represent a link between the Motagua source areas and jade-artifact consumers who lived farther north, this work has promise for tracing the economy of jade in Classic Maya society.

Beyond Iconography: The Application of Reflectance Transformation Imaging in the Study of Nasca Valley Rock Art Sites (Rio Grande de Nasca Drainage, Department of Ica, Peru)

This paper presents the results of our recent work at Nasca Valley rock art sites. In an effort to work with clear and objective methods of rock art documentation, we adopted Reflectance Transformation Imaging, a computational photography technique that combines a group of photographs taken with different light angles in order to create a three-dimensional representation of the surface. RTI images are helpful in documenting characteristics of petroglyphs that are often lost in line drawings or may not be clearly visible in single digital photographs, such as the superimposition of motifs and the different manufacturing techniques used. Our investigations enabled us to identify petroglyph manufacturing techniques in individual boulders and determine distinct manufacturing episodes at these Nasca Valley sites. Our research also addresses rock art conservation issues since RTI enables us to closely study the damage on rock surfaces due to natural weathering processes.

A Full Coverage Survey of the Middle Chincha Valley Corridor, Peru

The Programa Arqueológico Chincha explores the development of social complexity in the lower Chincha Valley, Peru. The valley contains evidence of intensive human occupation, covering the Early Horizon Paracas traditions through the late Inka incorporation of the Chincha kingdom. Previous survey work in the lower-valley describes monumental adobe architecture, platform mound building, and centralized infrastructure in the form of roadways and irrigation canals across this chronological span. These reviews place heavy emphasis on the massive edifices of the alluvial plain near the coast, largely glossing over marginal areas and underreporting smaller sites. We conducted a full-coverage survey of the middle-valley neck – a crucial transition corridor of some 50 square km, linking the larger coastal plain with mid-valley chawpiyungas. We report our results here: an assemblage of nearly 80 sites including domestic, mortuary, and defensive elements, ranging from the Early Horizon to the Late Intermediate Period. We discuss the implications of our data for interpreting the settlement systems of the earlier Paracas and later Chincha occupations of the mid and lower valleys, and suggest that the mid-valley transition area between the alluvial plain and chawpiyungas served as a key conduit in both the EH and LIP.

Feathered Serpent and Flowering Trees: Interpreting Images of Food and Reproduction Cycles in
Teotihuacan

We re-analyze representations of plants and animals in Teotihuacan to better understand indigenous conceptualization of food. We first identify the wide variation of plants and animals represented in Teotihuacan imagery to a species level from a biological/ecological perspective. Representations of plants and animals can be divided into two categories: 1) plants and animals utilized as food, utility materials, or symbols in the Mexican Highlands including maize, frijol, squash, cactus, maguey, amaranth, chia, or rabbit, deer, dog, wolf, puma, serpent and diverse lagoon birds, and 2) exotic organism such as cacao, cotton, four petals flower, or jaguar, macaw, and sea-shells. Representations of category 1 plants often show their fruits or seeds, indicating that the inhabitants realistically visualized subsistence resources within the context of local reproduction cycles highlighting the dichotomy between dry-wet, fire- water, and death-(re)birth. There were also category 2 representations of plants and animals specifically unidentifiable as they appear in general or abstract forms. They might have been brought from tropical areas and would have been used as symbols in ritual contexts and/or proclamation purposes. Feathered Serpent and Flowing Trees mural may indicate the extent of Teotihuacan’s rule, controlled by their supreme deity Feathered Serpent, well beyond the Mexican Highlands.

Nixon, Sam (University of East Anglia)

An Architectural Complex of the 12th-13th Centuries AD from the Eastern Arc of the River Niger (Republic of Benin, West Africa)

While building traditions in West Africa are most commonly associated with mud-architecture, examples of this tradition pre-dating the modern era are relatively rare due to its poor preservation and the rarity of its detection archaeologically. This paper provides an account of an excavated mud-architecture complex from the north of the Republic of Benin which has been dated to some 700-800 years ago, featuring individual rooms and various connected communal spaces. This well-preserved evidence is archaeologically unique due to the associated presence of pottery and laterite pavements throughout the complex, as well as other paved features. Pottery pavements have been documented relatively extensively within West African archaeology but rarely has evidence of significant structural remains been able to be detected in association with them. In addition, remains of a range of ceramic vessels destroyed in situ were recorded within the complex, including one buried within a pavement. That these remains come from one of the least archaeologically researched areas of West Africa provides an additional importance to their consideration within wider discussions of early West African architecture. The paper will also discuss the conditions dictating archaeological preservation of mud architecture in West Africa and the methods of its detection.

Nixon, Sarah (Indiana University South Bend) and James VanderVeen (Indiana University South Bend)

Experimenting with Functionality: A Case Study of the Caribbean “Water” Bottle

The true use of the pottery vessel form found across the Pre-Columbian Greater Antilles and known as the “potiza” remains a mystery. Its shape resembles that of a canteen or flattened bottle, and fragments have been found in and near fresh water springs. But was the complex vessel used only to collect water? Might its unique design also be an innovative response to the hot and humid environment? In an effort to better understand the purpose behind the potiza’s shape, a number of replica vessels were created and then specific attributes were tested. Aspects like evaporation rate, content temperature, and vessel stress during transport were recorded in controlled experiments. The results suggest the potters who designed and constructed the peculiar pots had a specific function, as well as symbolic form, in mind.

Grinding to Sustain Life: An Ethnoarchaeological Approach to Grinding Equipment Use in Northern Ethiopia

Grinding stones, also known as saddle querns and handstones, or metates and manos, have been in use by humans in food processing since the African Middle Stone Age and have been recovered from archaeological sites on all continents. As a major tool used in subsistence activities for many cultures, grinding equipment has the potential to provide insights into social constructions, such as gender relations, craft specialization, labour practises, community engagement and cooperation. So, how can the ethnoarchaeological study of grinding contribute to our understanding of the technological, social and economic context of grinding in ancient and present communities? My paper will review the data collected and insights gained through interviews and participant observations which document the technological and social interrelationships in the life history of grinding stones in a traditional (non-mechanized) rural setting.
in northern Ethiopia using Design Theory and the chaine operatoire approach and specifically focusing on the "use" of grinding equipment.

[81] The Anthropology of Archaeological Data Collection and Management

The design of an archaeological data repository’s structure has important implications for the ways archaeological professionals interact with the data. The Digital Index of North American Archaeology (DINAA) brings into focus the different choices SHPOs and other repositories make regarding data collection and management. When working with digital data, structure (e.g. booleans, lookup tables, text strings, categories of enumeration, etc.) functions in combination with vocabularies to frame our understanding of the archaeological record. While each state standardizes data collection through site forms and databases, prioritization of specific data categories in the collection process and the ontological system used to form the data necessarily create imposed and differing mental constructs of how archaeological concepts relate to one another. This creates operative differences in site definitions and different affordances for a researcher running queries through these imposed taxonomies of practice. DINAA circumvents these limitations created by the structures of our data communication systems. Although DINAA does not manage sensitive data, including site locations, it is a valuable tool available to interpret data sets for research, resource management, and outreach.

Nocerino, Eric

The archaeological record along the central coast of California has revealed that prehistoric Chumash groups developed a variety of coastal and terrestrial economic adaptations that influenced their settlement practices. However, the role of these adaptations during various stages of cultural change is less clear. This paper discusses the use of Geographic Information Systems (GIS) as a regional analysis tool for interpreting prehistoric Chumash settlement patterns at Vandenberg Air Force Base (VABF), California. GIS will be used to create a general model of the paleoenvironment from the early Holocene to the Late Period at the VABF. Central Place Foraging Theory will then be applied to the model to develop predictions about ideal and secondary site locations and the possible economic risks associated with those localities. Known sites from the VABF radiocarbon database will then be mapped over the environmental model and analyzed within this theoretical context. It is hypothesized that through time, long and short-term changes in the spatial organization of hunter-gatherer settlements at VABF were not only the result of terrestrial and coastal economic adaptations, but also a result of significant changes in the social organization of the Chumash as population increased in the region.

[146] Social Implication of Early Nasca Ceramics at La Tiza

The Nasca people on the south coast of Peru in the Early Intermediate Period produced an unusual amount of polychrome fine ware pottery. Early Nasca (A.D. 1-450) ceramics are found at the site of La Tiza, a substantial town site located at the conjunction of the Aja and Tierras Blancas rivers. I compare the ratio of fine ware to plain ware from La Tiza to two sites with Early Nasca components, Cahuachi and Marcaya. By comparing these three sites, it is possible to elicit a better understanding of the context in which fine ware and plain ware were used and produced in Early Nasca society. Additionally, differences in the distribution of elite and non-elite vessels within and among these three sites can shed light onto the variation in social stratification in Early Nasca society.

[172] Geochemical and Geophysical Survey and Intra-Settlement Activity Patterns: Pilot Study at a Series of Complex Sites in the Lake Erie Basin
Ohio archaeology saw early application of soil phosphate analysis; however, after a series of equivocal applications in the early 1980s little or no use was made of this avenue of investigation as an independent source of information about local or regional activity patterning. Meanwhile geochemistry has proven extremely useful for prospecting and activity pattern analysis in a variety of contexts. Analytical techniques have improved since the 1980s, and phosphate is once again being employed in Ohio. We present the results of a pilot application of combined soil phosphate and magnetic susceptibility soil survey at three sites in the Lake Erie Basin. Our results illustrate the value of the method for disentangling the formation history of three multicomponent sites. Especially when used in a multi-pronged research design, soil analysis is a powerful supplement to traditional techniques and enables whole-site analysis without full excavation.

Compositional Analysis of Ceramic Sherds from Southeastern Dominican Republic

La Cangrejera is a village-shore archaeological site that yielded radiocarbon dates, 1040 – 1490 AD, from mollusc shells. The site contained abundant Boca Chica ceramics and a small set of stylistically-distinct, painted-red ceramics that preceded the Boca Chica style by several hundred years. Our objective is to examine variation in the elemental composition of selected ceramics to determine if discrete typological motifs are characterized by unique compositional groups. We hypothesize if the distinct painted-red and Boca Chica motifs were constructed through unique approaches to the selection of raw materials for ceramic production, they will separate into distinct elemental compositional groups. Two hundred and fifty-four ceramic sherds were analyzed through neutron activation analysis at the Archaeometry Laboratory at the University of Missouri Research Reactor. The hypothesis that distinct typological styles are associated with discrete elemental compositions is not supported. Our results suggest selection of raw materials for ceramic production remained static as cultural motifs changed at La Cangrejera. Our study reveals continuity in the selection of raw materials across material culture boundaries and highlight the need for continued investigation of culture change in the Caribbean using diversified methodological approaches.

Noll, Christopher (Geo-Marine, Inc.)

Approaches toward the Replicable Classification of Archaeological Sites Based on Archaeological Survey Data

Throughout the history of archaeology meaningful classification of artifacts has been vital to analytical processes. The classification of archaeological sites is equally important to studies that investigate regional patterning in occupation, subsistence, and technological organization. The classification of archaeological sites is also a key attribute of archaeological site records throughout the United States. Classification can be completed relatively reliably on rigorously studied sites but those classifications based on survey data alone can be much more subjective. Furthermore, some site types utilized on survey based site records are non-specific. Cultural resource management archaeologists are often faced with the task of classifying sites without a replicable technique. The reliable and replicable classification of sites from survey data can be accomplished with the use of quantitative-based field procedures. This paper identifies ways that sites can be classified using simple, cost effective, and efficient methods. Sites from the Pacific Northwest are used to demonstrate the approach.

[105] Identifying Mortuary Ritual and Ancestor Veneration: A Spatial Analysis of the Tombs at Hualcayán, Peru

Ancestor veneration is a concept shared by indigenous peoples throughout the Andes. Identifying patterns in the spatial distribution of tombs on the landscape provides insight into how deceased ancestors were viewed in Andean cultures. This study is an investigation of the ritual activity associated with ancestor veneration in the Peruvian Andes through a survey of eighty tombs at the site of Hualcayán, in the north-central highlands of Peru. This survey included information about the location as well as form, size, and artifacts associated with each tomb. The results show significant variation in both size and complexity among the tombs at this site as well as a pattern of clustering. The clustering of these tombs was influenced by a combination of geographical factors as well as cultural choices, perhaps reflecting and reaffirming kinship ties through physical associations of tombs on the landscape.

Norman, Lauren (University of Toronto)

[160] Study of a House: Spatial Patterning of a Western Thule Winter Dwelling

Zooarchaeological remains have been studied at all scales of spatial analysis from across landscapes to within features; however, the intra-dwelling studies are in a clear minority, likely due to the paucity of remains normally found within houses and low-resolution collection strategies. Excavations of a Western Thule semi-subterranean dwelling at Cape Espenberg on the Seward Peninsula, Alaska, have yielded a well-preserved, high-resolution archaeofaunal assemblage. I map this data set using a GIS framework to explore the spatial patterns of multiple variables. These spatial patterns exist as part of the house floor due to past activity areas, taphonomic processes, and post-depositional developments. Understanding these processes of assemblage development is important for understanding past human lifeways for Western Thule people.

Norman, Scotti (Vanderbilt University)

[256] Conquest and Resistance in the Chicha-Soras: A Diachronic Study of Soras Opposition to Colonial Rule

In times of great political upheaval, new foreign leaders manipulate preceding state infrastructures and social networks to conquer local people. However, the creation of state power is never so one-sided; outside authorities must continually adjust tactics of control according to conditions “on the ground.” The resultant landscape of power occupies a “third space” in which contrasting cultures interweave to create an entirely new sociopolitical stage. In the Chicha-Soras Valley (Ayacucho and Apurimac, Peru), the Soras people experienced violent overthrow during Inka conquest, followed by Spanish seizure of both local and Inka spaces. During the early stages of both conquests, Soras people contested imperial presence, mounting a two-year siege against the Inka and later initiating the Taqui Oncoy resistance movement against the Spanish. Never completely subdued, the Soras actively shaped colonialism, and their overt rebellions taxed both empires. Social power was thus negotiated in the Chicha-Soras Valley, a product of the clash between Soras opposition and imperial goals of annexation and conversion. While Spanish documents suggest smooth conquest, spatial and material evidence provides a contrasting picture, demonstrating that outside takeover was a tenuous, negotiated, and multivalent process.

[322] Advanced 3D Imaging for Recovery of Weathered Stone Sculpture at Izapa, Mexico

A recently developed image capture technique called “Reflectance Transformation Imaging” (RTI) has for the first time been applied successfully to map the texture of weathered low relief stone sculpture, providing a new tool for accurate data recovery and drawing restoration. RTI permits computerized inspection of the stone surface with a full range of variable lighting and texture enhancement applications that recovers unseen details thought to be weathered beyond recognition. RTI field tests of Izapa Stelae 4 and 5 confirm the accuracy of the original NWAF Izapa sculpture project photos and drawings (from 1960 to 1976) with some additional details for an accurate permanent record of Izapa sculptures which was the objective of NWAF's original Izapa Sculpture Project completed in 1982.

Los trabajos de conservación e investigación que se han venido realizando desde 2006 en el Codz Pop de Kabah tienen como objetivo no sólo detener el deterioro y devolverle parte de su apariencia original, sino también entender al edificio a partir del estudio de su arquitectura, la iconografía de sus ricamente ornamentadas fachadas, los materiales asociados, así como de su ubicación dentro del conjunto palaciego del asentamiento, en donde residió la familia gobernante durante el período Clásico Terminal (800-1000 d. C.) y que debió ser un espacio destinado también a la administración y el ejercicio del poder político. La información recuperada a lo largo de estos años junto con el reciente hallazgo de dos jambas esculpidas en el cuarto 1 del edificio, ambas con una fuerte carga iconográfica, nos han permitido ampliar nuestro conocimiento sobre las transformaciones del espacio construido y las posibles funciones que ahí se desarrollaron a través del tiempo, así como acerca de la estructura social y política de los grupos de élite que habitaron en Kabah.

Novo, Alexandre (IDS North America Ltd.) and Beverly Chiarulli (Indiana University of Pennsylvania)

Archaeological Surveys Using Multiple Array Ground Penetrating Radar

The IDS STREAM X is one of a new generation of GPR units that are available for archaeological investigations in the US. The advantage of a Multiple Array GPR is that the instrument collects more data than single antenna units in the same amount of time, providing much greater resolution of subsurface features. The multiple lines of data are acquired simultaneously as the array moves along the surface. Channels within the array are closely spaced allowing a dense grid of sample points to be created combining full-resolution data acquisition with a robust integration of navigation and centimeter-accurate positioning. Researchers from IDS North America and IUP have used the multichannel STREAM X system for several surveys in Western Pennsylvania during the past year. In one part of the campus, the STREAM was used to investigate a 19th century industrial area later buried by fill and construction of a campus parking lot. The instrument was also used in a search for the burial pit of dozens of circus animals buried in 1893 after an infamous train wreck. This poster presents the results of these surveys and describes this new option for non-destructive prospection of large archaeological sites in North America.

Novotny, Anna (Arizona State University)

Defining Community in the Upper Belize River Valley during the Late Classic Period: A Micro-regional Bioarchaeological Approach

A methodological issue with the study of communities is the assumption that an archaeological “site” is analogous to a social community. Yaegar and Canuto (2000) define community as a constantly emerging social institution governed by suprahousehold interaction. If communities are created and sustained through interaction, they argue studies of community must fall between the levels of the household and region. Here, I apply the concept of a micro-region, larger than one site but smaller than the settlement region, to explore community among the ancient Maya of the Upper Belize River Valley during the Late Classic period (AD 600-900). A population increase occurred there during the Late Classic florescence of Xunantunich. It is unclear whether the influx of people was due to in-migration or not, although it has been proposed that Xunantunich leaders may have encouraged migration of farmers to support their city. I apply biodistance and isotope analyses from three mid-sized, geographically proximate sites – Chan, Chaa Creek, and Zubin – to address whether the increase in population was due to in-migration and how it affected community interaction. This analysis is novel in that it focuses on interactions within the non-elite community rather than between elites and non-elites.

Novotny, Claire (University of North Carolina - Chapel Hill)

Marginalized Landscapes and the Social Practice of Archaeological Research: Ancient and Contemporary Perspectives from southern Belize

This paper evaluates the social practice of archaeological research through an analysis of marginalized landscapes from the perspective of ancient Maya hinterland households and contemporary Maya villages. Situated in the Toledo district of southern Belize, the Aguacate Community Archaeology Project examines ancient Maya household socioeconomic integration with regional dynamics during the Classic period (AD 250-850). The cultural and geographic marginality of both ancient and modern southern Belize creates a distinctive landscape between perceived centers of power and influence. First, this paper uses archaeological materials from recent excavations at Kaqru’ Ha’, a small ancient Maya settlement in
modern Aguacate village, to shed light on regional social and economic integration. Second, this paper examines the engagement of the local Q’eqchi’ Maya community with the archaeological landscape. A marginalized archaeological landscape is created by a state-managed tourism industry that emphasizes the monumental architecture of ancient Maya cities; Aguacate villagers grapple with issues of local history, identity, and heritage tourism surrounding the modest archaeological sites on their land. Considering archaeological landscapes from ancient and contemporary perspectives situates research within a social context that recognizes the entanglement between the archaeological imagination and community heritage.

Nowell, April (Univ of Victoria-Dept of Anth) [115]  
Growing Up in the Pleistocene: Neandertal Children and the Evolution of Play Behavior

The life history pattern of modern humans is characterized by the insertion of childhood and adolescent stages into the typical primate pattern. This slowing of the maturational process provides humans with additional years to learn, transmit, practice and modify cultural behaviors. In both human and non-human primates a significant amount of their dependency periods are spent in play. Data suggest that Neandertals experienced shorter childhoods than modern humans. This is significant as there is extensive psychological and neurobiological evidence to suggest that it is during infancy, childhood and adolescence that milestones in social and cognitive learning are reached and play and play deprivation have a direct impact on this development. Faster maturation rates and thus shorter childhoods relative to modern humans lessen the impact of learning through play on the connectivity of the brain. Differences in the length of childhood and associated modes of learning may explain differences in the nature of the symbolic material culture associated with Neandertals and modern humans.

Celebrating Death: New Data on Recuay Mortuary Feasting Practices from Hualcayán (Ancash, Peru)

This study presents the analysis of excavated ceramic materials from a patio space outside a small familial (MNI=9) non-elite two-chamber subterranean Recuay tomb at the archaeological site of Hualcayán in highland Ancash, Perú (AD 1-700). Formal characteristics of the ceramic assemblage and their distribution and superposition within the patio space indicate that these materials are the remains of recurring ritual feasts to honor the dead. The assemblage included musical instruments and a high percentage of decorated jars and bowls suggesting that music and ceremonial drinking, likely with chicha beer, were the most important ritual practices performed during these Recuay feasts. Detailed attribute analysis of the assemblage also indicates a high variability of painted techniques, ranging from the careful preparation of sophisticated negative designs with complex iconography to vessels with more free-flowing, uneven paint strokes. The latter technique is the most prevalent. While these designs may suggest a lack of sophistication or care, we argue that the prevalence of these course techniques reflects on the one hand an aesthetic intended by their makers, and second, that these vessels were expediently prepared by living family members in preparation for the burial of their recently deceased family members.

Núñez-Cortés, Yajaira (University at Albany-SUNY) [113]  
“Fire God’s Animal”: Dogs from Mayapan

Dogs served a unique role for the ancient Maya. Not only were dogs eaten, but they were used for hunting, medicine, and rituals. Dog bones have been recovered in a variety of contexts at Mayapan, including shrines, colonnaded halls, temples, craftperson and commoner dwellings, and elite houses. Prior research indicates that dog bones appear in great quantities at specific monumental center structures such as the Templo Redondo and the Ch’én Mul Cenote temple, indicating their significance to
certain elites and for ritual practice. The special role of dogs in Mayapan's ritual economy is examined in this paper by looking at their distribution across architectural contexts of diverse function. The analysis includes skeletal element representation, age, and frequencies of dog bones, as well as the production of special items made out of dog bones such as drilled tooth pendants. Differences in the spatial distribution of dog bones are best explained by the variable social and functional contexts of dog use at the site. Means of dog acquisition for elite use will be considered, including dog raising, tribute, and other mechanisms.

[220] Chipped Stone Analysis from Two Middle Holocene Archaeological Sites in the East Central Great Plains

Current research on Middle Holocene bison populations from the east central Great Plains utilizes isotope analysis to illustrate low regional mobility. While this pattern has interesting implications for land use and territoriality for the human populations that exploited these herds, few published reports detail archaeological assemblages or address features of prehistoric mobility in this subregion. Here we address this question through an investigation of chipped stone raw material variability from two Middle Holocene archaeological deposits (the Hill and Simonsen sites) in western Iowa. Results indicate that the geographic extent of material sources supports an interpretation of restricted hunter-gatherer mobility within this subregion during the early years of the Middle Holocene in western Iowa.

[231] Indian Pottery at Fort Rosalie in Natchez, a French Colonial Outpost in the Lower Mississippi Valley, 1716-1763

Fort Rosalie in present-day Natchez, Mississippi was a key outpost in France's colonization of the Lower Mississippi Valley. Built in the heart of the Natchez nation in 1716, the fort was destroyed during the Natchez uprising of 1729, then rebuilt and occupied by the French until 1763, when the territory was ceded to England. Our analysis of the indigenous ceramic assemblage from the National Park Service excavations at Fort Rosalie highlights the engagement between French and Indian cultures in the Louisiana colony during the first half of the 18th century. Indian women produced ceramic vessels for the soldiers at Fort Rosalie, sometimes after having taken these soldiers as spouses. Our analysis of the pottery reveals how the vessel forms reflect Natchez accommodation of French needs and tastes while also illustrating how Native people participated in the frontier economy. A detailed analysis of historic plans and maps provides additional information on the archaeological contexts from which these ceramics were derived.

Nystrom, Kenneth (State University of New York at New Paltz)
[126] Embodied Inequality: Race, Class, and Anatomy in 19th-20th Century United States
Embody as the physiological response to cultural stressors has been considered by public health researchers and bioarchaeologists and provides valuable insight into how psychosocial stress and discrimination can negatively impact health. Within archaeology, embodiment also encapsulates how the body is modified to reflect cultural attitudes and conceptions regarding social identity. It is argued here that during the 19th and 20th centuries in the United States the identity of socially marginalized groups was linked to the living body. Race and class were intertwined vectors of inequality and both were considered to have bodily manifestations; racialization was most often predicated on 'biological' differences (e.g., skin color) while poverty was also considered an innate feature of a group. After death these embodied living identities legitimated the modification of their corpses into anatomical specimens used in medical training. While personhood was dissolved as the body became an object, the cutting, partitioning, and display of the dead body was ultimately grounded in a continuity of the living marginalized social identity. This paper will synthesize the available evidence of anatomization and present new data from excavations at the Erie County Poorhouse to discuss the complex relationship between race, class, and anatomy within the United States.

O’Boyle, Robert (University Of Montana), Alvin Windy Boy (Chippewa Cree), Virginia O’Boyle (Chippewa Cree), Jason Brown (Chippewa Cree) and Duncan Standing Rock Sr. (Ojibwe)

[77] Success and Opportunity: Consultation, Federal Agencies, and Indian Country
This poster presents the efforts of the Chippewa Cree Cultural Resource Preservation Department in preserving the culture of the Chippewa Cree. The Chippewa Cree, of the Rocky Boy’s Indian Reservation in North Central Montana, have been taking a proactive role in the preservation of significant cultural properties. From the online consultation, The Chippewa Cree Tribal Register, and the FEMA funded Cultural Resource Training Video, the Chippewa Cree have worked to stay proactive in the preservation of cultural properties critical to the survival of our people. These sites are not only archaeological or even sacred in nature, they are the biography of our people, and the stones and bones found across the land tell the story of the people who have been here for thousands of years. Working together with other Tribes and Federal partners the Chippewa Cree have moved forward our cultural preservation program to have real lasting effects to the resources, the tribe, and the public in general who have an interest in seeing culture preserved. Cultural resource preservation is the preservation not only of past, but of our language and our living culture, and most importantly the survival of the Chippewa Cree for generations to come.

OBrien, Lauren (Southern Methodist University)
[344] A New Look at the Communities of the Developmental Period in the Taos Valley
Throughout time, communities have moved and changed across the Southwest landscape. This can be seen during the Developmental period in the Taos Valley, as pithouse communities appeared during a time when multi-room pueblos and kiva architecture existed less than 30 miles away. To understand these changing communities and the decisions they made, we must first examine their use of space, both the locations they chose to settle and the structures they chose to build and inhabit. Investigations on this topic will shed light on many of the current debates of this area: the timing of Puebloan expansion into the Taos Valley, the direction and manifestation of this expansion, the identities of these groups, and the strategies they employed. Research on the Developmental period in the Taos Valley over the past 20 years has predominately been survey-based CRM projects. These projects have located and recorded many sites, but a comprehensive synthetic overview of this period, which is needed to look at these questions, is still necessary. Through an integration of the results of salvage and culture history based investigations (dating to 1950-1960), CRM projects, and current investigations, these lingering questions should be answered.

[190] The Application of Laser 3D Technology to Determine Common Origin of Ceramic Figurines, Stamps, and Whistles from Honduras

Over the years, several archaeological studies have focused on ceramic figurines, whistles, and stamps. One daunting question encountered by researchers involves the relationship of figurine to mold and whether production and common source could be demonstrated through traditional methods of analysis. Evidence gathered to date suggests a level of standardization might have existed wherein modifications to a basic theme were accomplished by individual makers. To demonstrate standardization thus production and common source, a correlation must be established between mold and its positive figurine, whistle, stamp or between artifacts. We analyzed sample collections from Honduras and report on the integration of data derived from laser 3D scanning technology with applications developed for metrological analyses to test goodness of fit and surface deviation. Methods described in this paper have implications for modal analyses of other forms of ceramic artifacts as well.

[282] Ideal Free Colonization of Australia’s Arid Zone

Australia’s colonizing populations spread rapidly around much of the continent about 45kya, but vast regions of the arid interior remained unpopulated for millennia and under-populated through the Pleistocene. Here we run preliminary tests of qualitative predictions derived from an ideal free distribution model to examine how human foraging decisions, demographic pressure, and environmental suitability interacted to produce this patterning in the timing and distribution of settlement.

[35] Sourcing Marine Shell in the Indian Ocean: Exploratory ICP-OES Analysis of Conus and Cypraea

By the mid-third millennium BC, complex overseas networks of interaction had been established between West, Central, and South Asia. Oman and the Indus Valley were important sources of marine shell for overseas trade to Mesopotamia. However, no in-depth comparative studies have been undertaken that include shell artifacts from these regions of trade. Although the locations of ancient shell fisheries have been hypothesized based on modern distributions of mollusc species, a geochemical analysis of modern and ancient marine shell from modern day Pakistan, India, and the Sultanate of Oman utilizing Inductively Coupled Plasma – Optical Emission Spectroscopy (ICP-OES) analysis will more firmly locate important shell fisheries in the Indian Ocean. ICP-OES analysis is one method used in the geochemical sourcing of marine shell, along with Oxygen Isotope analysis. This paper will present the results of a preliminary ICP-OES analysis of modern Conus sp. and Cypraea sp. from three different locations in the Indian Ocean: the Karachi coast, the Gujarat coast (Dwarka), and Ra’s al-Hadd in Oman. If this technique is viable, it will be possible to trace the source of objects made from important trade species found at inland sites in the Indus Valley, as well as in the Mesopotamian region.

[336] Woven Wonders: Research Options Through Advances in Conservation Examination and Imagery

Advances in conservation practices and imaging techniques employed at the Arizona State Museum have expanded the research options for over twenty-two thousand archaeological perishable objects assembled through systematic archaeological research. The project has provided increased access to the collection, initiated new conservation treatment techniques, and reduced material loss from the collection. The Woven Wonders project, funded with a Save America’s Treasure grant, has also resulted in a state-of-the-art visible storage vault with improved housing techniques and an adjacent interpretive gallery. A conservation survey database was created and photo-documentation protocols (including radiographs, xeroradiographs and other non-destructive techniques) were standardized to assess the object completeness, use ware, dye techniques, patterns of decay and use, and modifications. New treatments were studied and new outcomes have been established. The project is viewed as a continuum rather and an endpoint and is now a process for ongoing investigation and exploration. Ultimate goals from the project include long-term preservation and access to the collections, sustainable cultural bridges to tribal communities and constituents, and research products that are useful to multiple disciplines.
ODonnell, Sarah (Missouri State University)

Archaeologists have proposed several models of human habitation in the Missouri Ozarks during the Late Prehistoric period (A.D. 900-1500). These models position the Missouri Ozarks as an intermittently occupied zone, in contrast to adjacent regions occupied by sedentary and politically complex agriculturalists. Drawing on world systems theory, Ahler, Kreisa, and Edging (2010) propose an alternative model that positions the Missouri Ozarks as a margin in relation to the adjacent Cahokia Mississippian core. However, application of this model is constrained by uncertainty about the type of relationship that prevailed between Ozark margin societies and core (i.e., Mississippian and Caddo) societies. My study helps resolve this problem by using ceramic artifact data to clarify the nature of interaction between populations in the Missouri Ozark Highland and those in adjacent regions. Using shell- and limestone-tempered ceramics from sites within the Gasconade River Drainage, this study focuses on resolving questions of local versus nonlocal production. Analyses of ceramic geochemistry, via Instrumental Neutron Activation Analysis, indicate the manufacture of both shell- and limestone-tempered ceramics occurred locally, in close proximity to Gasconade Drainage sites. The results suggest a relationship of relative isolation between the Ozark margin and nearby core societies.

Oetelaar, Gerald (University of Calgary)

As social constructions, places provide important information on the way people experience and humanize a landscape. Humans experience a landscape through movement and define places based on the challenges of moving through a particular environment. The challenges depend on the available transportation technology and features of the landscape such as topography, hydrology, and vegetation. Repeated use of the same pathways connecting these landmarks generates a trail network whereas the places serve as anchors for the narratives, songs, and rituals of the group. Patterned movement along the trails past the succession of named places retraces the footsteps of the ancestors and becomes a combined ritual pilgrimage, historical journey, and social odyssey. The quotidian actions of the people while camped at places along the network of trails influence the local ecology creating a series of microniches or desirable resource patches scattered across the homeland. In this paper, I explore the archaeological and ecological signatures of such place construction on the northern Plains with particular emphasis on the evidence for the persistence and change in the nature of the constructed places.

[144] Mortuary Variability at Paquimé and Its Implications for Sociocultural Differentiation

The transition from the Viejo to the Medio period in the Casas Grandes region was marked by increasing sociocultural complexity at the core site of Paquimé. This is particularly evident in the burial practices and mortuary treatment of the individuals interred at the site. Our analysis focuses on the most complex burial discovered at Paquimé, a subfloor tomb containing the remains of at least 12 individuals. Burial 44-13 is comprised of two distinct "layers" of interments; the lower layer consists of six articulated skeletons and one skull, while the upper layer contains the disarticulated and fragmentary remains of five individuals. Here we evaluate the hypothesis that the upper level of human remains represents a sacred offering to the elite individuals below through a comparative analysis of health indicators, trauma, post-mortem processing, pathology, and taphonomy. Our results suggest that there are significant differences between the two layers, particularly in terms of post-mortem processing and age-at-death structure. We discuss these findings within the broader scope of mortuary treatment at Paquimé as a whole and argue that burial 44-13 enables us to more clearly contextualize changes in sociocultural complexity during the later Medio period.

[121] Inca Things and Local Audiences: Adopting Elements of Imperial Material Culture at the Local Level

For ancient empires, the agenda of incorporation and control of provinces did not entail the imposition of imperial material culture on provincial subjects. Instead, the adoption of elements of imperial material culture by local peoples was more of a voluntary phenomenon, but one that had many connotations.
regarding the political, social, or economic motives of those making and using items that drew from imperial material culture. This paper takes a theoretical approach to the phenomenon, examining how the motives of provincial individuals, their attitudes toward the imperial state, and their levels of participation in state ideology can be understood by focusing on the nature of the cultural elements being adopted, the contexts of their manufacture and use, and the audiences that would have seen those items in use. These points are illustrated with archaeological evidence from the Inca occupation of southern Ecuador and elsewhere, and implications for understanding pre-Inca empires in the Andes are discussed.

Ogiogwa, Joan-Mary

[Sungbo’s Eredo: A Construct of Sociopolitical Institution.]

Re-writing the history of the rain forest belt of West Africa has increasingly become a focal point in the present spate of researches on-going in the region. This is owed to the emergence of ‘new’ data mostly coming from the work of scholars such as Chouin (2009). Chouin’s work in Ghana has shown that contrary to the hitherto held views that the development of complex societies and the transformation of the forest of Ghana (and by inference the whole of West Africa) into farmland followed only after the opening of the Atlantic trade in the late 15th century—a theory propounded by Wilks, 1993, that there had been a process of urbanization that might even have had its beginning from around the first millennium CE. This pre-Atlantic urbanisation was characterized by the building of extensive and monumental earthworks associated with settlements as well as large expanses of land around such settlements. To this end therefore, the present paper attempts to make a further contribution to the ‘new’ data using results obtained from recent archaeological work carried out on the Sungbo’s Eredo, a 160km long earthwork in the rain forest region of south western Nigeria.

[Tephra Traps and Projectile Points: An Update on the Volcaniclastic and Cultural Chronologies at Rimrock Draw Rockshelter (35HA3855), Harney County, Oregon, USA]

Laboratory analyses of samples collected during the 2011-2012 excavations at Rimrock Draw Rockshelter indicate regional eolian and pyroclastic surge materials are collected in “traps” influenced by both mechanical and chemical weathering processes. These tephra accumulations range in size from microstratigraphic layers visible only through particle size and geochemical analysis to massive deposits of Mazama ash in the stream channel adjacent to the rockshelter. Identified ash samples include Newberry (1000 RCYBP), Mazama O (6850 RCYBP), and St Helens SG (13,000 RCYBP), the latter collected from buried deposits above fragments of cameldid teeth and a chalcedony flake tool. Trenching of both fluvial and eolian deposits in 2013 explored the relationship of erosion and deposition processes to cultural deposits within the rockshelter, yielding additional tephra samples to enhance the chronology of the region. Ash mantled clays preserve diagnostic artifacts associated with the Western Stemmed tradition; plus overshot flakes, bifaces with overshots, gravers, and fluting flakes that may be associated with fluted point technology. This paper, newly updated from the 2013 Paleoamerican Odyssey meeting reports the results of tephra analysis on samples collected from both archaeological and geologic deposits, and their relationship to diagnostic projectile points, extinct animal species, and radiocarbon dated features.

[Assessing Shape Variation of Early Holocene Bifacial Points from South-Eastern and Southern Brazil Using a Geometric Morphometric Approach]

Since the 1960s, most of the bifacial points found in archaeological sites from South-eastern and Southern Brazil have been lumped under the name Umbu Tradition, regardless of their geographical
origin or their chronological information. Through the application of geometric morphometric methods, this paper aims to test the hypothesis that there are important differences in the early Holocene bifacial points associated to the Umbu Tradition in South-eastern and Southern Brazil. We have analysed 248 bifacial points from South-eastern (states of Minas Gerais and Sao Paulo) and Southern (states of Parana and Rio Grande do Sul). The sample spans from the Early to the Late Holocene. Our results point to important differences in the morphology of the points from Minas Gerais, Sao Paulo, and Parana, while the materials from Rio Grande do Sul suggest a greater morphological homogeneity. The differences observed among different regions may suggest that there is a hidden and not yet truly recognized morphological diversity within the Umbu Tradition.

Oland, Maxine (Smith College)  
[338]  "With the Gifts and Good Treatment That He Gave Them": Elite Maya Adoption of Spanish Material Culture at Progresso Lagoon, Belize  
Spanish artifacts make up a tiny percentage of all artifacts found on the west shore of Progresso Lagoon, a 15th-17th century Maya community in northern Belize. Textual references suggest that Spanish encomenderos distributed these objects as "gifts" during reduction and pacification efforts, but the careful distribution of these artifacts suggests specific political and economic choices made by Maya individuals. This article compares Spanish material culture from Progresso Lagoon with other Maya sites along the frontier of the Spanish colony, in an attempt to define how strategies of Maya consumption of foreign objects varied with intensity of colonial interaction, social status, and function. The consumption of Spanish artifacts at Progresso Lagoon suggests elite strategies for retaining legitimacy in the uncertain political and economic climate of the fifteenth through seventeenth centuries.

Olguín, Ivan  
[238]  Impostión cultural y superposición arquitectónica en el centro cívico-ceremonial de Teotitlán del Valle, Oaxaca.  
La Zona Arqueológica de Teotitlán del Valle, Oaxaca, ubicada en el centro de dicha comunidad, se distingue por los admirables mosaicos de grecas de piedra que decoran el basamento prehispánico del Periodo Postclásico (900-1521 d. C.), que al parecer sostuvo un complejo Cívico-Ceremonial zapoteco con edificios administrativos y residenciales similares a los que se encuentran en los sitios arqueológicos de Yagul y Mitla. Como en este último sitio, en Teotitlán se puede advertir una imposición cultural, manifestada por la superposición de un templo católico sobre un edificio prehispánico. En coordinación con el Centro INAH-Oaxaca y con la colaboración de la comunidad de Teotitlán del Valle, en el año 2012 se realizaron trabajos arqueológicos en el basamento prehispánico mencionado, adyacente al templo católico construido por la orden de los dominicos en el S. XVI. Con esta exploración se pudo registrar una serie de materiales arqueológicos, así como varios elementos arquitectónicos que corroboran la persistencia de los vestigios del recinto Cívico Ceremonial zapoteco por debajo del Templo católico, mismos que serán expuestos en esta ponencia.

Olszewski, Deborah  
[236]  Early Epipaleolithic (Nebekian) Strategies in the Western Highlands of Jordan: Wadi al-Hasa Region  
Early Epipaleolithic groups in the Levant have often been described as highly mobile. Although there are a few exceptions to this characterization (e.g., Kharaneh IV and Ohalo II), most sites are aerially small and said to represent short-term camps. This creates a scenario in which hunter-gatherer-forager groups were essentially constantly on the move. In this paper, we use information from the sites of KPS-75, Yutil al-Hasa, Tor Sageer, and Tor at-Tareeq in the Wadi al-Hasa region of Jordan to examine the concept of mobility and the “meaning” of site size and site type in the Pleistocene landscape. We argue that aerially small sites do not necessarily constitute short-term occupations, but as highly visible archaeological places in the landscape, they represent investment in place akin to the concept of “persistent places.” Sites that might indicate high mobility would have been quite ephemeral and often are not recorded by traditional surveys which focus on identifying highly visible sites rather than on systematically recording “nonsite” locales.

[191]  Shaping Identity along Maya Trade Routes: The View from the Highland-Lowland Interface
Recent research at a number of sites on trade routes along the Maya highland-lowland interface detected a range of cultural identities within a narrow geographic region. Material culture at Sebol, in the Alta Verapaz, indicates a populace with a strong highland identity while Cancuen, to the north, is a lowland site. Located between these sites, Raxruja Viejo is a large center with an amalgamation of highland and lowland features. This paper explores ways in which these sites, as nodes in ancient trade routes, drew from different regions to build identity, as reflected in material culture.

O'Meara, Carolyn (UNAM)
[73]  Physical and Linguistic Marking of the Landscape – Are They Connected?
One way humans mark or delimit the landscape they inhabit is through the naming of places. While there are numerous studies of the toponymies of the cultures of the world, it is not clear what kinds of places get named cross-culturally (see e.g., Burenhult & Levinson 2008). Humans also leave physical markers in their landscape, not just in the form of evidence of a camp site, for instance, but also markers with informational content. This work looks at toponyms in Seri (using data from Moser & Marlett 1995 and the author), a hunter-gatherer group living in northwestern Mexico, to see if there is an overlap between the types of geographic entities that receive toponyms in Seri and the places that are the result of physical modification. In particular, Seris had a common practice of burying their child's placenta in the desert near to its birthplace, sometimes accompanied by the planting of a cactus. It has been shown that Seri identified a larger area surrounding the burial site as corresponding to “their territory” (Hine & Hills 2000), however, these areas do not correspond with a named place.

[29]  With Their Backs to the Ocean: Socioeconomic and Cultural Reconfiguration in Hebridean Scotland c 1250 to c 1450
Systemic changes in settlement structures and exploitation regimes in the Hebridean islands of Scotland in the two centuries after 1250 CE have been interpreted traditionally as consequent on primarily political factors. Shifts across that period from deep-water marine exploitation to inshore fishing and from mainly arable cultivation on the calcareous shell-sand machair districts to intensive pastoral activity on the interior ‘black-land’ areas evident in the archaeological and historical record, however, point to long-term societal responses to environmental change. While benefiting from a broader range of resource exploitation opportunities than were available to their Iceland and Greenlandic kinsmen, the responses of the Hebridean population to a range of environmental impacts resulted in social and cultural reconfiguration at fundamental levels. This paper explores those changes in the context of North Atlantic weather patterns and long-term climatic deterioration at the close of the MCA. It considers the impact of increased North Atlantic storminess, coupled with raised precipitation and falling temperatures, on the economic regime established in the region in the twelfth and thirteenth centuries. It concludes with discussion of the collapse of external market-oriented production, elite consumption and tribute-gathering within a subsistence economy, and the (re-)emergence of predatory behaviour.

[249]  Introducing a New Complementary Geochemical Approach for Obsidian Sourcing: The Case of the Western Mediterranean
Since the 1960s, and the first “real” sourcing campaign of obsidian artefacts by Cann and Renfrew (1964), analytical methods used to characterise obsidian and other rocks have seriously improved in precision and effectiveness. The use of analytical techniques such as PIXE-PIGME, SEM-EDS, XRF, INAA, ICP-MS or LA-ICP-MS, have led to various degrees of success, and methodological problems still
remain (artefact's size, surface regularity, soil contamination, etc.). While most of these techniques allow the characterization of the main obsidian sources, some artefact's provenance remain problematic, requiring more enhanced methods. To overcome these questions, we propose to use a multi-isotope ratio analysis. The use of multi-isotope ratios has been widely applied in geological research, but never to obsidian sourcing for archaeological purposes. In this study, we review the application of several characterization techniques (SEM-EDS, XRF and LA-ICP-MS) in a geologically well-known region, the west Mediterranean area, and then compared the results obtained with the new method.

[188] Time Maps: Site-Intensive Lichenometric Survey at a Planned Colonial Town in Highland Peru

Late prehispanic and colonial-era settlements in the highland Andes often present extensive and complex architectural remains. We present a lichenometry-based methodology for dating such settlements. Though well established as a dating method in earth sciences, lichenometry remains underutilized in archaeological research in the Andes, despite its reliability, cost-effectiveness, and simplicity. In this case, we recorded metric and qualitative data on Rhizocarpon geographicum specimens growing on the surfaces of fieldstone buildings at a large planned colonial town (reducción) in southern highland Peru with extensive architectural remains and a four century occupational sequence. The results of this site-intensive survey provide near 100% coverage of lichenometric data from the architectural remains of the settlement, with over 800 specimen measurements. Prior studies established a growth curve, enabling absolute dating of building construction and abandonment. GIS-based analysis defines the sequence and extents of construction and occupation through a series of interpolated date surfaces. The results define the areas corresponding to prehispanic occupation, the initial construction of the colonial settlement, and areas remodeled or overbuilt during the mid- and late-colonial eras. We also discuss potential broader applications of the methodology.

Orijemie, Emuobosa

[40] Late Holocene Environmental Change and Cultural Response in South-Western Nigeria

The environmental changes in the late Holocene (4500-2000yrs B.P.) of south-western Nigeria were very dramatic altering vegetation, precipitation and river systems. These changes included the complete disappearance of the mangrove swamp forest, decline in hitherto diverse rainforest, significant lowering of sea levels and influx of freshwater into swamps. The hitherto dense rainforest environment provided a base for the local subsistence economy synonymous to hunter-gathering of terrestrial and aquatic resources. Local communities also maintained interactions with culturally-similar groups in Bénin and Ghana. Upon the subsequent marked increase in freshwater, establishment and spread of secondary forest and coastal savanna, economic adaptation turned to agricultural practices for food production. This shift in culture though was the main way to achieving food security and sustainability, altered the environment beyond its threshold. These major contributing factors along with the introduction of foreign cultures promoted by colonialists prevented the re-establishment of the mangroves and rainforest.

ORourke, Mike

Much of the Arctic archaeological record is situated along or near the modern shoreline. These coastal sites are at substantial risk of damage or outright destruction by numerous processes which continually reshape the Arctic coasts. Such processes have been forecast to increase in severity and scope as climatic conditions continue to change in the years ahead, a situation which has necessitated new ways of thinking about regional-scale archaeological resource management. The threats of relative sea level rise and accelerating rates of shoreline erosion have been employed through GIS analytical frameworks to promote an informed approach to resource management by highlighting regions most at risk. Archaeological resource 'value' is a complicated and often contentious measure of public interest which has been mobilized in the management of heritage resources around the world. The uncritical application of value-measures in archaeology has been heavily critiqued however, and for good reason. Such critiques appear to have prevented the use of 'value' in GIS-based heritage management frameworks. This paper outlines my efforts to align notions of 'value' and 'threat' through the establishment of an archaeological site 'vulnerability model' for use in the dialogical management of archaeological sites along the Beaufort Sea, NWT, Canada.

O'Rourke, Laura
[204] **The View from Las Galeras, a Small Olmec Site in the Region of San Lorenzo**
The relative absence of stone at Las Galeras, a village in the hinterland of San Lorenzo, highlights how the tight control of imported stone into the region of San Lorenzo in the late Early Formative period was one of the ways that the ruling elite of San Lorenzo wielded and manifested economic and social power in this early civilization. Stone had to be imported into this region of clay and sand; the raw basalt and andesite stone that was used to create monumental architecture and sculpture, as well as the obsidian used in rituals, was also used to make utilitarian tools. As an imported and restricted commodity, the line between utilitarian and luxury is fluid: the obsidian blade that cuts into an animal and the basalt mano and metate that grind food are utilitarian implements; at the same time, the scarcity of these materials makes them luxury goods. In this way, the multiple uses of stone and the difficulty in obtaining it blurs the line between the everyday and the ritual.

Orozco, Joseph (CSULA)

[70] **An Examination of Faunal Remains from Midnight Terror Cave**
Over the course of three seasons from 2008-2010, California State University, Los Angeles conducted an intensive surface survey of Midnight Terror Cave. These investigations documented extensive modification of the cave to create broad, level areas suitable for public ritual. The project also recovered extensive human skeletal material thought to be the remains of sacrificial victims. Additional evidence of ritual comes from faunal remains associated with ritual features in the cave. In the course of the analysis, 682 animal bones were examined at Cal State L.A. The assemblage is unusual in containing high frequencies of fish and bird bone, but two species commonly identified in Maya ritual assemblage occur in low numbers. White-Tailed Deer (Odocoileus virginianus) and Ocellated Turkey (Meleagris spp.), which typically make up the largest amount of mammal and bird bone respectively in documented assemblages, are represented by only a single element each at Midnight Terror Cave. There are relatively few cave faunal analyses published so it is not possible is establish the nature of a typical cave assemblage but it is startling is see how divergent the Midnight Terror Cave assemblage is from others. A number of suggestions will be advanced for why this might be.

[118] **The Capitalist Mode of Production and the Postcolonial Project**
Postcolonial studies have appeared within almost every discipline, including archaeology. Historical archaeologists using postcolonial theory have tended to adopt two approaches to the subject of capitalism: either they have neatly sidestepped it or ignored it completely, or they have claimed to be studying it while actually masking its impacts. Even some historical archaeologists who have investigated the post-1500 CE modern world have adopted these strategies. The seepage of neoliberal strategies into postcolonial studies has significantly hindered our ability to critique the capitalist project. Now is the time to reclaim the original radical and Marxist roots of the postcolonial perspective and to reinsert the mode of production concept within it.

Ortiz Vallejos, Jose Raul (University of Arizona)
[312] Regional Interaction in the Northern Maya Highlands of Guatemala
Recent archaeological excavations at El Soch, Guatemala, a site located along the Chixoy River on the eastern end of the Cuchumatanes Mountains, have provided new archaeological data concerning the development of societies in the northern Maya highlands of Guatemala, but they have also raised a number of questions about how archaeologists should approach broad regional inter-comparisons of material culture. Although this region has only been sporadically addressed by systematic archaeological research, it is promising the evidence gathered at El Soch portrays a dynamic region with the interaction and movements of people, ideas, and goods. This dynamism is found in all sub-regions in the northern highlands, though mainly between the eastern Cuchumatanes and the Alta Verapaz regions. This paper summarizes the ceramic chronology and the construction sequence of El Soch suggesting that shifts in material culture assemblages and practices from the end of the Early Classic to the Late Postclassic can be understood as indicators of regional interaction between different social groups across the northern highlands. I propose that significant social processes and events, such as migrations and expanding trade networks, could explain some regional patterns in the northern Maya highlands in different phases of its chronology.

Ortman, Scott (CU-Boulder)
[289] Economic Development in Pueblo History: Methods and Data from the VEP
Recent work in macroeconomics suggests that culture, and especially ideas that impact the scale of social coordination, are an essential ingredient of economic growth. It also suggests that growth does not derive from specific details of a capitalist economy but from more general aspects of human technology and sociality. These emerging perspectives create an important opening for a renewed dialogue between archaeologists and economists which may also lead to a greater role for archaeology in the public discourse. In this paper, I propose methods for translating the archaeological record into measures that are relevant for studying growth processes in the past and apply these measures to the episodes of Pueblo history that are the focus of the Village Ecodynamics Project. These analyses suggest that significant economic growth took place during the Chacoan era and in the century following the migration of Pueblo ancestors from the central Mesa Verde to northern Rio Grande study areas.

The practice of trophy taking is a human activity that has been documented globally throughout time. In the Eastern Woodlands of North America, it was prevalent during the late Middle and Late Archaic and found at many (n=22) sites along major waterways in the Ohio and Tennessee River Valleys. Outside of this area, there is a marked decrease in the occurrence of trophy taking. This indicates an area of densification of trophy taking that deserves further investigation. Reasons for delimitation of trophy taking in this region are explored through analyses of trophy victims, distinguished by missing limbs or crania associated with perimortem cut marks, and articulated limbs and crania buried as grave goods. The meaning and power of trophy taking events, both removal and deposition, is examined using perspectives of post-mortem agency, which highlights the ways in which body parts retain the identity and agency of the individuals from whom they were harvested. Thinking about trophies in this manner contextualizes the ways trophies were used to establish and maintain group identity and social boundaries in the Ohio- Tennessee River Valleys during the late Middle and Late Archaic.

Osterholtz, Anna (University of Nevada Las Vegas)
[28] Patterned Processing as Performative Violence at Sacred Ridge
Violence serves social functions. Performative violence is used to reinforce social behavior and to create and reinforce social relationships between aggressors, witnesses, and victims. Sacred Ridge (a PI site in southwestern Colorado) is a large EP (Extreme Processing) assemblage where at least 33 individuals were killed, disarticulated and fragmented, and their remains placed within a pit structure. The crania, in particular, exhibit consistent patterning in fracture distribution and type, mutilation, burning, tool marks, and missing bone; this indicates that individual crania were treated similarly regardless of age or sex. Distribution of the remains within the pit structure indicates that the crania were deposited in a fragmented state, meaning they would have been unidentifiable as individuals and possibly as human beings. This presentation explores the patterned processing of the crania as performance. The roles of the aggressors, witnesses, and victims associated with this assemblage are explored through this performative lens.

[206] The Problem of Space Averaging In Zooarchaeological Data from Central Western Argentina: Different Interpretations about Resource “Intensification”

The possible existence of a resource intensification process had been debated widely in central western Argentina. However, spatial units used to support the intensification model have not been critically considered in previous publications. Intensification process had been proposed considering southern Mendoza region as a unique spatial unit. This analytical lumping could have caused wrong interpretations about changes in faunal consumption during the Late Holocene. In this paper we show that changing the spatial analytical units produce different interpretations of faunal consumption in the past. Depending on the size of the spatial scale, the differences in the taxonomic richness through time will be sharper or lighter.

[334] Incised Stones of the Great Basin: Associations and the Archaeology of Context

This paper explores the close associations incised stones have with other artifacts at two sites in the Great Basin. Incised stones are small, portable, mostly flat objects that have designs incised on the surface. Left at caves, rock-shelters and open-air sites, these stones are a poorly understood artifact class not only in the Great Basin, but also worldwide. The placement of an incised stone beside other artifacts in just one excavation level may not hint at a pattern. However, my research examines every excavation level with incised stones from two sites: Hogup Cave, and Ruby Cave. In each site, incised stones have been grouped with their closest artifact neighbors. Does a pattern emerge? After a brief introduction of the chronology of incised stones, a combination of plan maps, graphs, and photos will walk through the deposition of incised stones. Patterns in the record will be discerned, and suggestions of what these patterns mean will be made.

[293] Turkey, Beef, or Veg? Diachronic and Synchronic Variation in commoner Household Production and Consumption Practices at Xaltocan, Mexico
With the proliferation of household archaeology in Mesoamerica, archaeologists have increasingly carried out extensive, detailed excavations of domestic structures and associated features. Such excavations and greater attention to spatial context within household space have provided scholars with the opportunity to reconstruct the practices of everyday life in households. However, Mesoamericanists have less often been concerned with interpreting these data in terms of the decisions of individual commoner households. Drawing on theories of agency and practice, this paper examines commoner production and consumption practices using faunal evidence from sealed middens adjacent to domestic structures. In particular, it considers variation in these practices along both diachronic and synchronic axes. It reconstructs how members of the household known as Structure 122 altered their animal-related production and consumption practices as their broader political and economic contexts changed—ranging from the height of Xaltocan’s power in the 13th century, to the rise of Mexica and other Nahuatl-speaking groups in the mid-14th century, to the early colonial era. It also reconstructs how such practices differed between families—comparing the Structure 122 and 124 households and patterns evident at the site-level—at a single point in time, during the early colonial period.

[235] Regional Perspectives on Shellfish Gathering from the Ryokyo Islands, Japan
The antiquity of shellfish gathering along the RyOkyO Islands dates from the region’s earliest inhabitants into the modern era. Invertebrate remains from the RyOkyO Islands, Japan were identified using traditional zooarchaeological methods to determine the contribution of shellfish to the diet during the Middle to Late Shellmidden period (4000 B.C. to AD 1100). I quantify spatial and temporal variations at intra and intersite levels, and use ethnography to place mollusk gathering in the unique socio-historical context of these three shellmidden sites. The addition of these data to existing studies contributes to our knowledge of food procurement strategies, changing subsistence patterns, and paleoenvironmental reconstruction during this time period.

[270] From Ideology to Identity: Epitaph Memorialization in the History of the American Cemetery
This presentation examines epitaph popularity and content in north-western Pennsylvania from the beginning of the 19th century to the present, and situates these trends within the context of the wider monument industry, prevailing ideologies and constructions of personhood, and, material forms. Notable trends in popularity, visibility, origin, and content can be seen to characterize epitaph use during this period. The extent to which detailed studies of memorial texts further our understanding of the ideologies that inform, and are actively manipulated by mourners and the funerary industry alike, will be examined.

[195] Dzehkabtún (Campeche, México) – un Sitio Maya en la Zona Transitoria entre Puuc y Chenes
En 2012 comenzaron las investigaciones sistemáticas en el sitio maya de Dzehkabtún (Campeche/México) por el Proyecto Arqueológico Dzehkabtún (Instituto Ibero-Americano de Berlín) y con financiación por la Fundación Científica Alemana (DFG). Los resultados de las primeras excavaciones en 2013 indican que el sitio fue habitado desde el Preclásico Medio hasta el Epiclásico o el Postclásico Temprano. Aparte del levantamiento topográfico y una reconstrucción virtual en 3D de la arquitectura del sitio, el proyecto actual se dedica a analizar el contexto sociopolítico en la transición del Clásico al Postclásico en el área del Chenes, así como las causas del abandono de este sitio y de la mayoría de los sitios del Clásico en el centro de la península de Yucatán. Por un lado, los resultados de la primera temporada de excavaciones estratigráficas indican una continuidad marcada entre los habitantes del Clásico Tardío/Terminal y los constructores de edificios tipológicamente epi- y postclásicos en Dzehkabtún. Por otro lado, revelaron una ocupación inesperadamente marcada ya desde el Preclásico Medio y una amplia participación en las redes de intercambio de larga distancia durante el Clásico Temprano y Tardío.
Pacheco Arias, Leobardo (Universidad de las Américas Puebla-Zona Arqueológica de Monte Albán)

[238]  Contexts of the Religious Architecture in Atzompa, Oaxaca

Among the most impressive buildings made by the ancient Zapotec people who lived in the Valley of Oaxaca during the prehispanic era are their places of worship. Their building design, decoration and associated offerings made of ceramic allow us to study some aspects of ancient Zapotec religion and rituality. Here, we examine the architectural and ornamental features of five temples, four of them explored in the core area of the Monumental Complex of Atzompa (Buildings 3, 4, 6 and 16) and one on its periphery (Building 1 at Plaza K). These buildings, excavated between 2007-2012, are architecturally similar but with their own characteristics, are compared with those of the great city of Monte Albán that were built around the Late Classic Period. In addition to describing the patterns of distribution and construction of these temples, we seek to explore the links with recent archaeological objects found in these contexts, such as Zapotec effigy vessels.

Pacifico, David

[59]  Urban Households and Social Hierarchy at El Purgatorio, Peru

Following radical urban ethnographers, archaeologists have recently turned to examination of houses, households, and communities for understanding the way in which non-elites and their everyday practices contributed to large scale urban processes. This paper presents research from the residential district at El Purgatorio, Peru, dated to the latter part of the Late Intermediate Period (ca. AD 1300-1400). This research employed a "neighborhood archaeology" approach founded upon household archaeology and the community archaeology of Yaeger, Canuto, Wernke, Mac Sweeney, and others. Analysis of residential architecture in the popular residential district of El Purgatorio indicates that social hierarchy and household configuration were interrelated at El Purgatorio. This interrelation suggests that household configuration and kinship were important factors in the development of inequality at El Purgatorio. However, the examination of ceramics and organics recovered from these residences suggests that material inequalities in portable goods were not as pronounced. While preexisting social inequalities were brought to the city and further developed there, citywide economic institutions may have also worked to diminish material inequality between residents of diverse social statuses.

[31]  Is There an Ek Complex in Central Yucatan? Evaluating Early Ceramics from Yaxuna and Aktun Kuruxtun

The Preclassic period in the northern Maya lowlands has been a focus of intense discussion for the past 15 years. Several projects have reported new data that indicate that the Ek ceramic complex from Komchen should predate Early Nabanche pottery and would thus date to the transition from the Early to Middle Preclassic. These data, however, come from the western side of the peninsula, and little is known about the material culture that existed at this transitional point in Central Yucatan. In this paper we discuss the ceramics and radiocarbon dates from two sites in the Yaxcaba region that bear on the transition to ceramic-using communities. Early dates from Yaxuna indicate that a version of Early Nabanche pottery dates as early as 1000 B.C. and is mixed with Ek ceramics that may have been imported. Dating from Aktun Kuruxtun corroborates these early Early Nabanche dates and provides evidence that Yotolin Burnished, a type that George Brainerd placed within the Early Preclassic, may be indicative of a subcomplex associated with the earliest Early Nabanche pottery in Central Yucatan.

Pailes, Matthew (University of Arizona)

[200]  Refinement of the Río Sonora Chronological Sequence

The Río Sonora region continues to suffer from a lack of chronological control and, in particular, temporally sensitive diagnostic artifacts. In addition, the region lacks refined typological classifications of ceramics and other classes of material culture. These two problems are obviously closely related. Previous research in the area relied upon C14 analysis and a classification of architectural styles. This is extremely problematic since architectural styles are not mutually exclusive between periods, and vary widely across space. Reliance on C14 data is also problematic due to the wide error ranges inherent to
the calibration of dates from the 15th to 17th centuries. This paper will begin to address these issues by presenting 18 thermoluminescence dates, most made directly on Río Sonora Ceramics, from the Moctezuma Valley. Dated samples were preferentially selected from floor and other contexts to simultaneously evaluate architectural styles. Results provide preliminary ages for a variety of Río Sonora textured types and several styles related to the Casas Grandes tradition. These data allow an initial formulation of late period occupation in the Moctezuma Valley and a basic comparison with previous models based mainly on Sonora Valley data.

[116] Technological Approaches to Stone Tool Production: The Case of Layer 2 of Mesolithic Shellmidden of Cabeço da Amoreira, Muge (Portugal).

The discovery of the Muge shellmiddens dates back to the nineteenth century and is recognised to be of high importance to international Mesolithic studies. Located near the Tagus River, in central Portugal, this complex has provided high quality Mesolithic faunal remains, human remains, and lithic assemblages. This study will focus on the technology and typology of lithic artifacts, from the Layer 2 of Cabeço da Amoreira from the Muge Mesolithic complex. One of the main goals is to understand the importance of the various raw-materials present at the site and their relation with the different techno-typological aspects. This study seeks to advance our knowledge of economy, functional and stylistic elements, and its relation to the emergence of social complexity in the Muge Mesolithic communities.

[197] The Maya Highlands and the Pacific Coast: Two Important Regions for the Development of Social Complexity of Southeastern Mesoamerica

Sites located on the Maya Highlands and Pacific Coast of Guatemala demonstrate complex developments that some have proposed represent the emergence of some form of state society. The importance of this area dates back to the Preclassic period, but it is only briefly mentioned in historical accounts of the region. The diverse architecture and sculpture manifestations from these two regions show intense cultural exchange between them and other areas from the Maya lowlands, Eastern region, and Central Mexico. The sites located in these zones have great importance and relevance for the understanding of Mesoamerican sociocultural developments. This paper will summarize the state of studies in these areas and their relationship with neighboring regions.

[222] Cremations in Contexts: the Micro-stratigraphic Investigation of Population and Practice at the Middle Bronze Age Cemetery of Békés Jégermi-kert, Hungary

Demographical and pathological attributes of a cemetery population’s skeletal remains can be suggestive of living conditions of people during ancient times, but these data are obtained from cremated remains with greater difficulty. The fragmentary state and special fracture patterns of cremated bones may hide or destroy analytically relevant signs, and the removal of fill from cremation urns further fractures and reduces the amount of anthropologically useful morphological and metric information. Our paper focuses on the bioarchaeological results of the Middle Bronze Age (2000-1500 BC) cemetery of Békés Jégermi-kert in Eastern Hungary, where most bodies were cremated before final interment. During our analyses, we used classical anthropological methods in combination with the layer-by-layer micro-stratigraphic excavation of cremation urns supported by images derived from computed tomography (CT). We demonstrate how the combination of CT visualization, in situ micro-excision data, and the anatomical and metric characteristics of bony fragments informs us not only about the living conditions of ancient times, but also about mortuary practices of the community that rarely get documented.
Palacios-Fest, Manuel

[267] *Paleoecology of the Blackwater Draw, South Bank, New Mexico*

The paleoecological reconstruction of Blackwater Draw in eastern New Mexico is of major significance to understand the environmental impact on human occupation in the arid Southwest. This study uses diatoms and microinvertebrates (ostracodes and mollusks) to identify patterns of environmental change for the time span between the Last Glacial Maximum (LGM) and the early Archaic period, covering the most important geoarchaeological episode, the Clovis occupation, in the region. Diatoms are abundant and show distributional patterns based both on salinity and brine composition. Ostracodes and mollusks, by contrast, are rare but indicate the pond's water chemistry and stream flow.

[172] *A Comparative Analysis of Local and Non-local Chert Usage at Two Late Prehistoric Sites in South Western Pennsylvania.*

Recent investigations of Late Prehistoric lithic assemblages have reported the appearance of numerous chert types. Many of these investigations explored the significance and variation of local chert sources. However, there has been little research into the use of non-local chert type in Monongahela lithic assemblages. Onondaga and Loyalhanna chert sources can be found in close proximity to many Late Prehistoric sites in Western Pennsylvania and constitute the majority of the lithic material found in these assemblages. Non-local chert types such as Flint Ridge, Upper Mercer, and Jasper have also been identified in many of these lithic assemblages. This research utilized an intersite and intrasite comparative strategy to identify the differences in lithic reduction strategies between local and non-local chert sources. Two temporally and geographically similar Late Prehistoric sites in South Western Pennsylvania were used in this study. Lithic analysis exploring variation in lithic industry, technological organization and curation were carried out at the individual site level. The results from the individual site analysis were then compared to identify any distinct variation between the two sites.

[72] *Metal Tools in Lacandon Maya Economics*

Metal tools of European manufacture quickly entered the exchange networks in the remote southern Maya Lowlands during the Spanish colonial period. While metal tools did not completely replace Maya stone implements, including chert projectile points and scrapers, machetes and axes became essential for native agriculture and local economies. This presentation covers the history and archaeology of the introduction of Euro-American metal tools to Lacandon Maya and their ancestors in Peten, Guatemala, and Chiapas, Mexico, and how these items transformed indigenous trade and agriculture.

Pallan Gayol, Carlos (INAH, Mexico/University of Bonn, Germany) and Antonio Benavides Castillo (INAH, Mexico, Regional Center Campeche)

[195] *The Hieroglyphic Monuments from H-Wasil, Campeche*

At the heart of the Puuc region lies the site of H-Wasil, in Campeche, a few kilometers west of Labna and south of Kabah. It was first reported in 2007 by Antonio Benavides Castillo and included in the surveys conducted by Stephan Merk. The authors present here the results of a more in-depth field documentation and epigraphic analysis of the site's epigraphy. Standing architecture at H-Wasil displays Late- to Terminal Classic features, and of special interest is a small group of monuments with hieroglyphic inscriptions. The present paper deals with their decipherment and seeks to contextualize these findings into a broader perspective encompassing regional interaction among Puuc sites, as an effort toward overcoming the still prevailing lack of epigraphic documentation and analyses in this region when compared to other parts of the Maya lowlands. This type of work, when extended to several other sites in the Puuc, could then serve as a foundation for enabling historical reconstructions of such aspects as geopolitical interaction and prevailing rulership institutions and sociopolitical conditions during the decades immediately prior to the collapse and abandonment of numerous sites within this region.

[109] *A Preliminary Analysis of the Robberg Assemblage at Erfkroon*
The site of Erfkroon, located in the western Free State of South Africa, contains an artifact and faunal assemblage that spans the Middle and Later Stone Ages. It has produced the only excavated Robberg assemblage found at an open air site in southern Africa. The majority of the assemblage consists of bladelets and bladelet cores which typify Robberg lithic assemblages found in caves and rock shelters on the South African Cape and interior. A Lockshoek component found stratigraphically above these artifacts helps demonstrate that these microliths fit squarely within the Robberg industry. These bladelets, along with cores, raw materials, processed faunal remains, multiple hearth features and the site’s proximity to water, reflect camp activities. An analysis of tools and debitage revealed that both upland and nearby fluvial hornfels and cryptocrystalline sources were utilized for the acquisition of raw material. This paper provides an introductory analysis of the lithic technology used during the Robberg industry at Erfkroon and a comparison to cave and rock shelter Robberg assemblages.

[28] Creating a Better Understanding of Prehistoric Peoples through Reanalysis of Collections of Commingled Human Remains
Recent reanalysis of the Lewis Jones Cave Ossuary (LJCO) collection (1SC42) of commingled human remains provides insight into the burial behavior of prehistoric peoples living in northern Alabama during the Middle Woodland period (A.D. 100-500). Excavated from a natural cave site in St. Clair Country, Alabama, the LJCO collection of human remains exemplifies Copena mortuary practices through the inclusion of copper and galena burial goods. Reanalysis of the LJCO collection involved the recording of age, sex, pathological indicators, and taphonomic features of nearly 1,300 skeletal elements. Assessment of these variables led to an estimation of approximately 62 individuals and initiated the process of segregating the bone elements into separate individuals. Observation of the physical characteristics of each bone element, specifically the biological features, indicated a diverse population interred within the cave ossuary including individuals of both sexes, all ages, and with varying pathological conditions. Results of this nature suggest prehistoric peoples utilizing Copena mortuary practices in northern Alabama did not practice a separation of individuals during the interment process. Conducting reanalysis of collections of commingled human remains, such as the LJCO collection, may provide a better way to understand the sociocultural practices of prehistoric peoples through their mortuary behavior.

Panich, Lee (Santa Clara University)
[338] Diachronic Trends in Bead Consumption at Mission Santa Clara de Asis
Archaeological investigations at California’s Mission Santa Clara have recovered thousands of shell and glass beads from a variety of temporal and spatial contexts. In addition to numerous glass bead types, mission-era deposits from Santa Clara have yielded large quantities of beads from two distinct California shell bead traditions: clamshell disk beads and beads manufactured from Olivella shells. In contrast to expectations about technological replacement and decline, archaeological evidence from throughout the colonial period demonstrates that the mission’s Indigenous inhabitants continued to use multiple types of shell beads—many likely acquired from other regions of California—alongside glass beads imported by Euroamerican colonists. This paper will examine diachronic trends in bead consumption as revealed through both incidental and intentional deposits, including residential areas, mortuary contexts, and other deposits that may be related to Indigenous mourning ceremonies. Beads from these contexts are
examined with an eye toward understanding how Native Americans at Santa Clara acquired beads of different materials and how they incorporated them into existing yet dynamic cultural practices. The diversity of beads in circulation at Mission Santa Clara suggests Indigenous peoples exercised considerable flexibility in negotiating the constraints to bead access and use posed by Spanish colonialism.

[263] Woodland Perishables in McCreary County, Kentucky
This poster presents the results of analyses of Woodland-era cordage, matting, and slipper fragments recovered from the Spring Branch Shelter (15McY319) in McCreary County, Kentucky. Comparison with contemporaneous perishable assemblages shows intra-site variation in warps, selvages, and other textile structures and may indicate the presence of two different textile traditions. These findings suggest that the local social group was not homogenous. Expanding interregional interactions encouraged and increased the exchange of information and technologies during the Woodland period. Perishables from the Spring Branch Shelter are an example of these large-scale processes at the level of a site.

[222] Mortuary Practice and the Emergence of Middle Bronze Age Communities on the Great Hungarian Plain
The practice of cremation was introduced to the Great Hungarian Plain near the beginning of the Bronze Age and within 1500 years was virtually the only form of burial treatment of the Plain. This was also a time in which dense settlement and complex trade networks emerged, expanded, and collapsed. In this paper, we trace the arc of changing mortuary patterns across the Bronze Age (2700-750 BC) of the Great Hungarian Plain. We provide chronological and social context for the emergence of the Middle Bronze Age communities that built new trade routes, complex social relationships, and regional identities. We create a backdrop for the several research papers presented in this session, which seek to understand the rich social variability expressed during this regional florescence.

[161] Late Preclassic Southeastern Mesoamerica, beyond the Maya Construct
During the Late Preclassic, southeastern Mesoamerica was constituted by population nuclei usually described in terms of political entities and ethnic groups. But what is an "ethnic group"? Where should ethnicity be looked for? Terms like Maya, Xinca or Lenca have been used in recent decades to explain
population dynamics during the Late Preclassic. But, how are these human groups archaeologically defined? This paper introduces new archaeological data recovered from field seasons between 2007-2011, focused on monumental sculpture from present western El Salvador, and discuss local symbols and regional dynamics as a productive archaeological approach to group boundaries, contentious ideologies, and local configurations. Additionally we discuss modern bioarchaeological methods in order to obtain other perspectives on human group behavior, represented by biocultural practices, biological affiliation and pathological conditions, among others.

[10] Chemical Sourcing of Obsidian Lithic Fragments from the Grissom Site (45KT301) to Study Intra-site and Inter-site Source Variability

The Grissom (45KT301) site, located in northeast Kittitas County, Washington, dates from 2500 B.P. to the Historic period. While much of the assemblage remains unanalyzed, recent preliminary analysis revealed a high frequency of obsidian chipped stone artifacts. A technological, functional and material analysis of 165 pieces of obsidian in addition to XRF analysis of 49 pieces was undertaken in order to provide information on the number of obsidian sources represented, source frequencies through time, and the distribution of sources across space. Nine unique sources were identified in the XRF analysis, one of which was a local tachylyte source. While questions about source frequencies through time could not be definitively answered, source variation across space is higher in the southern part of the site than the northern part. Source variation across technological classes met expectations, but an intersite comparison did not show an expected pattern between distance from source and source abundance.

[37] Kings of the Hills: Borders and Boundaries of Early Postclassic Polities in Highland Chiapas

This paper investigates the multifaceted ways that the borders and boundaries of small polities in highland Chiapas were defined and maintained during the Early Postclassic period. This region formed part of the western frontier of the Maya linguistic and cultural area, and has been characterized as a relatively autonomous economic and political periphery. Beginning in the Late Classic period, a network of small polities proliferated throughout highland Chiapas. Over time, polity boundaries and interpolity relationships shifted as populations expanded and contracted, and the sociopolitical turmoil of lowland Maya polities to the east wrought transformations in long-distance exchange networks. Archaeological data can be used to examine the degree of porosity in spatial and social boundaries between highland polities, and the renegotiation of polity boundaries over time. The rulers of highland polities such as Moxviquil synthesized the natural and built environments to create defensible monumental centers, while also using architecture to manifest internal social divisions. We argue that polity boundaries were both permeable and mutable, as the populations and political influence of particular polities waxed and waned over time. Interpolity exchange relationships, and perhaps alliances, are reflected through the distributions of architectural styles, luxury goods, and utilitarian items.

Parker, Megan (Georgia State University) and Christopher Morehart (Arizona State University) [70] Culture vs. Behavior: Can We use Archaeobotanical Data from Ritual Contexts in the Maya Lowlands to Document Environmental Change?
If ancient Maya cave sites were loci for ritual, is it possible to use archaeobotanical data from them to understand environmental change? The often formulaic and canonical dimensions of ritual should instruct us on how cultural models of reality mediate peoples' practices. If plant remains recovered from ritual contexts were in fact key elements of ceremonial assemblages, they possibly cannot be used as direct proxies of environmental changes. But such a statement does not mean they cannot be considered proxies for how people responded to changes in their ecological, political, and social worlds. We examine this issue using archaeobotanical data recovered from several cave sites in the upper Belize valley. We study spatial and temporal patterns of variation in these caves' archaeobotanical assemblages. Using data from over 15 sites allows us to investigate this question while also dealing with different sampling factors. The patterns of variation we document not only reveal the importance of considering how culture mediates human decision making. It also allows us to consider the broader social universe within which ritual practitioners lived—a socio-ecological and political context that conditioned not only their daily lives but also their ritual ones.

Parker, Evan (Tulane University) [88] Heritage Conflict Arbitration and the Media in Post-Katrina New Orleans
In the wake of Hurricane Katrina, the press played a key role in ensuring the protection of the archaeological and historical heritage of the City of New Orleans. This paper examines the media coverage following the disaster and how it shaped the conflict between those who advocated for the recovery of the city's cultural patrimony and those who believed that the reconstruction of New Orleans was ultimately misguided. In the midst of this conflict, archaeologists, historians, and residents promoted the renewal of one America's richest historical treasures, yet the amplification of their voices through the press tipped the conflict in favor of reconstruction. As a result, much of the archaeological and historical heritage of the city has been preserved. Yet new conflicts have arisen with regards to the future of the city's heritage. These conflicts continue to undergo arbitration via traditional and alternative media organizations.

Parkyn, Andrew, Armin Schmidt (GeodataWIZ Ltd: Geo Data + Visualisation), Chris Gaffney (University of Bradford) and Roger Walker (Geoscan Research) [157] The MSP40: A Multi-sensor Platform for the Geophysical Evaluation of Sensitive Archaeological Landscapes
Mobile sensor platforms are now often used for archaeological geophysical surveys, with many of the developments coming from Continental Europe. The development of such platforms has mainly focused on a single sensor type, albeit offering multiple sensors, depths of detection or frequencies, but has not considered the physical impact on soil. The Geoscan Research Mobile Sensor Platform (MSP40) was designed to improve survey efficiency and remain a lightweight system. The platform can collect measurements from three earth resistance configurations simultaneously, showing directional variations of the current's flow through the soil. Additional sensors were integrated on to the hand-pulled cart to record simultaneous fluxgate gradiometer and microtopographic data. The MSP40 has been tested on a number of different soils at various times of the year with encouraging results. However, the continuous
collection rate and combination of techniques means a slight drop in data quality is inevitable when compared with manually collected data. The increased data density, availability of multiple-sensors data and improved rate of collection offset any slight reductions in data quality. The research has shown that the MSP40 can perform low-impact rapid site assessments on ‘vulnerable’ sites, whilst maximizing the information gained from a single traverse.

Parris, Caroline (Tulane University)

Refitting Refuse: An Assessment of Late Classic Maya Depositional Behavior

Refitting studies in archaeology have been used to investigate the creation and alteration of the archaeological record by both cultural and natural forces. From assessing the organization of technology to the evaluation of post-depositional stratigraphic disturbance by rodent burrowing, refitting studies can inform on a wide range of behavioral and taphonomic topics. The current study applies refitting methodology to pottery sherds in an attempt to reconstruct the depositional processes involved in the creation of a Late Classic midden deposit from the Maya site of La Corona, Peten, Guatemala. The formation processes associated with this deposit will be used to illuminate specific pre-depositional behaviors of the La Corona Maya. It is proposed that this midden is the result of a single consumption event whose remains were quickly processed and intentionally disposed. This study contributes to our understanding of Maya trash disposal practices and emphasizes the addition of refitting methodology to ceramic studies of large midden deposits for the reconstruction of ancient behavior.

El cambio formal de algunos edificios de la zona arqueológica del Templo Mayor: El caso de las estructuras A y B.

El recinto sagrado de Tenochtitlan ha sufrido diversos cambios a lo largo de su historia constructiva. Cada uno de los edificios que integran el conjunto se fueron modificando en un lapso de alrededor de 200 arios según las necesidades del conjunto ceremonial. En especial, se puede observar que el grupo de edificios que ocupan el area central del recinto muestran un desarrollo vinculado al del Templo Mayor. Este trabajo describe los diferentes momentos constructivos que se pueden observar en algunos de los edificios de la zona arqueológica del Templo Mayor, tanto en sus elementos constructivos como en su forma general. Nos concentramos especialmente en el caso de los edificios A y B, y su relación con el principal inmueble tenochca. Justamente estas estructuras muestran algunos cambios importantes a nivel formal pues modifican no solamente sus dimensiones, sino algunas de sus partes constitutivas.

Obsidiana - Continuidad Prehispánica e Integración en el Periodo Colonial Temprano, Centro de México

La obsidiana fue un material estratégico y multifuncional en la época prehispánica, se empleó en actividades productivas, militares y religiosas. Después de la conquista en el periodo Colonial Temprano, continuó empleándose en varios oficios artesanales europeos. Sin embargo, su utilización hasta nuestros días, se debe a los atributos mágico-religiosos asignados tanto por indígenas como por los europeos.

Patch, Shawn (New South Associates, Inc.) and Sarah Lowry (New South Associates, Inc.)

Midden, Mound, and Village: Archaeological Geophysics Survey of the Raccoon Creek WMA, Jackson County, Alabama

Prior archaeological investigations in the upper Guntersville Reservoir in northeastern Alabama have indicated intensive occupations during the Woodland and Mississippian periods. The purpose of this paper is to discuss the results of a large-scale geophysical survey designed specifically to address several research questions related to prehistoric occupation in this area. We focus on the archaeological interpretations and inferences drawn from complementary geophysical datasets. Attention is called to intra- and inter-site feature patterning, comparisons with other archaeological investigations, identification
of stratigraphic and geomorphic elements that influenced prehistoric activities, and the use of geophysical datasets to assist in agency planning and the management of archaeological resources.

Pioneer and Pilgrim: James Brady and the Archaeologies of Space, Place, and Landscape

Over his thirty year career, James Brady has contributed significantly to the archaeologies of space, place and landscape, as among one of the earliest to recognize the key role of caves in the political and religious dimensions of ancient Mesoamerican life. Early on, Brady argued that caves, as with the natural world in general, provided elite justification for political domination. By equating the body politic as an organism, alive and part of a larger cosmic order, elites had a powerful metaphoric tool that defined difference and inequality as a given; inescapable if not a moral prerogative. Starting from this point, I explore how Brady’s examinations of caves and pilgrimage have shaped archaeological discussions of landscapes in recent years and the potential direction of research in years to come. Using my own work on pilgrimage and religious authority, I argue that current frameworks of landscape and cave archaeology have the potential to move beyond elite centered analyses and consider the ways in which these spaces are important for understanding ancient gender and class dynamics.

Paterson, Alistair (Uni of Western Australia)

Human Uses of Barrow Island in Recent Centuries

Barrow Island is a significant target for a range of activities known to have occurred along the West Australian coastline, as well as a hazard to shipping given the wreck of Australia’s earliest shipwreck in 1622. After 1800, the island may have been visited by American whalers, explorers, and pearling vessels. Leases were granted by the colonial government to various pastoralists, turtle hunters, guano harvesters, and fishers. A shortly lived Lock Hospital for Aborigines may have existed, as well as a slave market run by pearlers. By the early 20th century, the island was a natural reserve, then oil field after WWII. The BIAP project is surveying the island for historical sites for the first time. The results of the 2013 season have revealed the presence of Aboriginal people and others at several locations. The sites will require particularly fine-grained dating of single episode events using historical materials to match locations with historical events, many of which exist outside historical records.

Contact and Communication in Southern Gaul, 400-600: The Ceramic Evidence

The traditional historical narrative of late antique Gaul is one of gradual fragmentation and regionalization as a result of the so-called “barbarian migrations” and the fall of the Western Roman Empire. Archaeologists have attempted to verify this narrative, based on the written sources, by searching for objects of supposed barbarian manufacture. The focus on such objects as projectile points, weapons, fibulae, belt buckles, and other items of “personal adornment” has effectively marginalized the study of ceramic evidence in western Europe for the period between 400 and 600 CE. I propose to address this lacuna on the basis of several recent surveys of ceramic finds from southern Gaul (modern southern France between the Loire and Garonne rivers). In doing so, I propose that we can trace lines of contact across the region on the basis of the ceramics evidence. I will use this evidence to illuminate the extent to which local communities participated in networks of communication and exchange in the late antique Mediterranean. I propose that through such a study, it will be possible to determine whether processes of regionalization took place, and to what extent such processes may have predated the arrival of barbarians in southern Gaul.

[A166] *A Changing Valley, a Changing People? An Examination of the Prehistoric Occupation of Warner Valley, Oregon*

Warner Valley, Oregon was occupied as early as the terminal-Pleistocene (~11,000 radiocarbon years ago [14C] BP). Random and intuitive pedestrian survey performed over the course of three field seasons by the Great Basin Paleoindian Research Unit (GBPRU) in the northern portion of the valley, which has been designated the Northern Warner Valley Study Area (NWVSA), has resulted in over 100 newly-recorded sites dating to the Paleoindian and Archaic periods. This paper considers all site data (e.g., site size and location, types of tools present, lithic debitage attributes) as well as x-ray fluorescence data for a large sample of obsidian projectile points and debitage from the NWVSA. Data derived from the site and artifact sample facilitate the reconstruction of land-use by prehistoric groups in the NWVSA and surrounding region. Additionally, the analysis of temporally discrete sites and isolated diagnostic projectile points aids in determining if prehistoric behavior in Warner Valley changed through time.

[42] *Mesmerizing, Sacred Place at Tank Mesa Village in Montezuma Canyon, Utah*

Tank Mesa Village, located in the Montezuma Canyon in southeast Utah, shows at least three occupational events during the late Baskemaker III/early Pueblo I, Pueblo II, and Pueblo III periods. Unlike many of ancestral Pueblo sites in the Four-Corners area, settlement patterns at Tank Mesa Village display multiple occupations that are uninterrupted. The earliest occupation occurred around A.D. 600, and a hiatus took place for at least one generation; ancestral Pueblo people returned and constructed two different villages around mid-1100s and around 1200. On the basis of recent reconnaissance and mapping of the site, we argue that the Tank Mesa Village site was a mesmerizing, sacred place for ancestral Pueblo people for several generations. Our argument is not only supported by the evidence of uninterrupted, multiple occupations of the site but also by the existence of nearby, elaborate rock art panel and potential water shrines.

[93] *Reconstructing Health and Diet: Interpreting Patterns of Dental Pathologies in Two Classic Maya Populations*

Osteological analysis of human dentition is an important tool in the reconstruction of past lifeways. Teeth contain a wealth of information about ancient diet and health and tend to preserve well even when the rest of the skeleton does not. The skeletal remains analyzed in this study come from the Classic Maya sites of La Corona and El Perú-Waka’ in Petén, Guatemala. The following indicators of health and diet are examined: linear enamel hypoplasias, caries, calculus, antemortem tooth loss, and dental attrition. The patterns and prevalence of these pathologies, when analyzed by age, sex, social status, etc., will provide important insight into Classic Maya life in the lowlands. These data will be articulated with the larger corpus of knowledge about Maya health and diet and will contribute to our growing understanding of Classic Maya life.

Patterson, Thomas (University of California, Riverside)

[118] *Modes of Production in Southern California at the End of the Eighteenth Century*

Looking at archaeological and ethnohistorical evidence from Southern California through the lens of modes of production raises interesting questions about our understanding of the practices and institutions of First Nation peoples who lived immediately before and after the arrival of the Spaniards in the late eighteenth century. This paper considers the questions of terms--like money, barter, trade, and exchange--and their ambiguity, which potentially clouds out understanding of evidence.

[291] Accessing Mid-Scale Collective Identities in the Past: New Bioarchaeological Perspectives on Kinship

The application of social identity theory to bioarchaeological research has proven relevant for accessing various dimensions of social organization and the lived experience of past peoples. Despite its recent visibility, most of this research focuses on large-scale collective identities including gender, ethnicity, and religion from the perspectives of individuals and larger social groups, while mid-scale collective identities remain largely under-investigated. Kinship is an essential mid-scale identity for which (bio)archaeology can provide deep-time perspectives, insights that are increasingly significant given the ever-changing definitions of relatedness emerging concomitantly with rapid cultural transformations and new reproductive technologies. This paper provides historical background on the practice of kinship studies in bioarchaeology, highlighting the recent resurgence of kin-focused ethnographic research. We present examples of bioarchaeological research designs that embrace a) the greater resolution provided by new methodological and analytical developments, and b) more nuanced conceptions of “family” in order to move beyond the mere identification of biological kin in mortuary contexts to using kin-based identity as a framework for investigating sociopolitical organization. This paper will provide the theoretical orientation for the symposium while emphasizing the potential of family-focused bioarchaeological research to explore the interconnectivity of individual, kin-level, and population-level social identities.

[119] The Joy of Archaeology at the Mission of Sorrows: Investigations at Mission Los Santos Ángeles de Guevavi

Mission Los Santos Ángeles de Guevavi, a unit of Tumacácori National Historical Park, was among the earliest Spanish colonial missions in the Arizona-Sonora region active from 1691-1775. Mission Guevavi has been the subject of several archaeological surveys and limited excavations since the early 20th century. In 2013, a University of Arizona Archaeological Field School investigated several damaged and threatened contexts at the mission site, including the mission midden and an adobe structure of unknown function that may be an earlier church. Excavations in the mission-period midden illuminated mission ranching and agricultural activities, as well as Guevavi’s engagement with a regional and global economy. Our initial field season also revealed several features of the site that were previously unknown, including the presence of additional structures in and around the mission compound. Planned research at the site in 2014 will reveal additional details regarding the age and function of the two adobe structures.

Pawlowicz, Matthew (Virginia Commonwealth University)  
[58] Pursuing the Local in the Swahili World: Survey of Songo Mnara Island, Tanzania

The Swahili communities of the East African coast have attracted quite a bit of attention from the breadth of their cultural and economic connections to the African interior and, especially, across the Indian Ocean. Yet Swahili cities were independent, competitive entities and the nature of their participation in those large-scale networks varied considerably. Drawing on data from a recent full coverage survey of Songo Mnara Island outside the walls of the well-known 15th-century site, this paper suggests that we can achieve a better understanding of that variation by exploiting a relatively underutilized scale of archaeological analysis on the coast – the immediate hinterland surrounding Swahili cities.

Pawn, Ian (Florida State University)  
[291] Kinship at Tiszapologar-Basatanya: A Bioarchaeological Study of Genetic and Affinal Relations during the Early to Middle Copper Age on the Hungarian Plain

The Early to Middle Copper Age (4500-3500 B.C.) on the Hungarian Plain is well known for shifts in settlement patterns, trade, and mortuary treatment. Regional bioarchaeological studies have focused on defining the nature of interaction during this dynamic time. However, it is not well known how these changes in social organization affected concepts of kinship. The sociodynamics of the Copper Age likely influenced both genetic and affinal relationships between individuals; therefore cemeteries, containing both people and representations of identity, are valuable sources of information. This paper will examine Copper Age kinship using Tiszapolgar-Basatanya, a large cemetery spanning the Early to Middle Copper Age. Researchers have argued that rows of graves, maintained over long periods, may have represented kin groups. This study examines this concept using similarities in dentition with
clusters of graves as the unit of analysis. However, kinship is not merely defined by genetics; this study will also use burial treatment and associated funerary objects to nuance understanding of the nature of kinship during the Copper Age. Drawing upon perspectives from gender archaeology, the paper will focus on affinal kinship and uses a combination of spatial patterning, mortuary treatment, and the identification of family structures in cemeteries.

The Arkansas Archeological Survey Model of Archaeological Practice: A Case Study

From its inception, the Arkansas Archeological Survey (AAS) has advocated a multi-stranded approach to archaeological practice. Centered on research, the model also encompasses preservation and public communication. In his 20 years directing the AAS, Tom Green has expanded on this basic approach, championing new research techniques such as geophysical survey while actively promoting preservation efforts and collaboration with descendant communities. The Eaker project offers a case study of the classic AAS model of archaeological practice. An effort spearheaded by Green to establish a curation facility in northeast Arkansas led to community and legislative efforts to establish a national park at the Eaker site. These, in turn, resulted in the creation of the Survey’s Blytheville Research Station and the Delta Gateway Museum. Research initiated by the Blytheville Station to support the national park efforts drew on geophysical survey to inform excavation and yield insights into broad-scale interpretation. And, crucial to the project was collaboration with the Arkansas Archeological Society, the Quapaw Tribe of Oklahoma, the City of Blytheville, the Center for Earthquake Research and Information, the Blytheville Courier News, and local civic groups. In sum, the Eaker project benefited from multiple strands of archaeological practice introduced or encouraged by Green.

Subsistence, Settlement, and Social Stratification on the Great Hungarian Plain during the Transition to the Copper Age

This paper concerns itself with hunting and animal domestication during the Late Neolithic (5000-4500 cal B.C.) and Early Copper Age (4500-4000 cal B.C.) on the Great Hungarian Plain. Intensively occupied tell sites and other surrounding flat areas characterized the landscape of the Carpathian Basin during the Late Neolithic. During the Early Copper Age, these tell sites dissolved into smaller, more widely dispersed settlements. Chi-square analysis of faunal data from Szeghalom-Kovaschalom and Veszto-Magor, two Late Neolithic sites, shows that hunting was more prevalent on tell sites than on flat areas. Additional analysis of the Early Copper Age sites of Veszto-Bikeri and Korosladany-Bikeri shows that the frequency of hunting and the occupation of tell sites declined simultaneously during the Early Copper Age. I propose that the variation in the faunal assemblages of tells and flat sites during the Late Neolithic can be attributed to a social hierarchy in which hunting was a luxury of the tell populations. Additionally, I conclude that the decline of hunting and dissolution of tells in the Early Copper Age is evidence of a rejection of that social hierarchy, which would have endangered the existence of the smaller and more interdependent Early Copper Age sites.

A Critique of the Thematic Approach for Assessing the Significance of Historical Archaeological Sites

A thematic approach is a common framework for assessing cultural properties from the Historic period in a CRM context. While there are some evident advantages to this approach from a humanistic perspective, it is faulty from a scientific perspective for several reasons, including a lack of attention to variability, incommensurable scales, the inescapably contemporary nature of themes, the minimal likelihood of anything new being learned, and the inherent subjectivity of a humanistic approach. Attempts to match some themes (e.g., ethnic lifeways) with the archaeological record have met with very limited success. Employing the Principle of Representativeness is an alternative approach under which both scientific and humanistic concerns can be addressed.

Bioarchaeological Perspectives on Social Status in Early China

Based on analysis of skeletal collections from Neolithic and Bronze Age sites on the Central Plains of China and using funerary contexts as proxies for social status, we evaluated the consequences of social inequality and gender roles. In assessing burial status, we considered the number of grave goods, their type, and the materials they were made of, as well as the size, construction, and location of the burial chamber. Skeletal health parameters were divided into those reflecting juvenile health, health during adulthood, and traumatic injuries. During both the Neolithic and Bronze Ages, sex of the deceased was the best predictor of burial wealth. The wealth of funerary offerings and indicators of health were correlated in the Neolithic assemblage; these associations were weaker, but also significant in the Bronze Age assemblages. The most distinct differences in parameters contributing to health status were those for skeletal traumas and the occurrence of systemic infections in comparisons between sample sets from cemeteries ranked by us as higher or lower in status. These findings offer compelling evidence that social inequality significantly affected the distribution of health risks and access to resources in China by no later than the end of the Bronze Age.

There is a New Curation Facility in Town: Strategies for the Development of Educational Programming, Outreach and Social Media

The Dr. John D. Cooper Archaeological and Paleontological Center opened its doors in July of 2011 and became fully staffed in August of 2012. The Center is a partnership between Orange County Parks and California State University Fullerton and is the repository for Orange County, California's archaeological and paleontological material. After collecting material for almost 40 years, the County dedicated funds to build a Curation facility and laboratory to ensure the proper care and curation of millions of artifacts and specimens. Part of the mission of the Cooper Center is to provide educational programming and outreach to the greater community. In the last two years the staff and volunteers at the Center have developed programming, outreach, and social media in an effort to increase awareness and education within the community and beyond with the ultimate goal to demonstrate the value and importance of archaeology, cultural history, paleontology, and natural history to the public. We will share the different strategies and approaches we have taken in the past two years and discuss those that have proven most successful.

Comparing the Nature of Aggregated Settlements across the Zuni/Cibola Region

The eleventh through the thirteenth centuries A.D. were marked by a trend toward aggregation across the Zuni/Cibola region, as formerly dispersed households increasingly clustered in small areas, often centered on large public architectural features. In some areas, it is relatively easy to identify spatially distinct communities surrounded by unoccupied expanses. In other areas, clear settlement clusters are difficult to objectively define. These differences in our ability to identify clusters archaeologically likely arise from variation in the nature of social integration, boundedness, and the scale of communities across the region. In this paper, we formally compare aggregated settlements through time (ca. A.D. 1000-1300) in several well-surveyed portions of the Zuni/Cibola region (Lower Zuni River, Pescado Basin, and the El Morro Valley) along three dimensions of variation: 1) the demographic and spatial scale of clustering, 2) the frequency, nature, and geography of integrative activities, and 3) the degree of population mobility.
This comparison will allow us to better understand differences in the trajectories of community formation and organization across the Zuni/Cibola region as a whole. This research draws on Linda Cordell's perspectives on the processes associated with aggregation and the establishment of large villages and towns across the northern Southwest.

Pena, Felicia (Department of Anthropology and Middle Eastern Cultures, Mississippi State Univ.) and Molly Zuckerman (Department of Anthropology and Middle Eastern Cult) [303], The Pox Enters the Space Age: Assessing the Impact of Mercury Treatments for Acquired Syphilis on Health in 17th to 19th Century London Using PXR

Mercury was the most commonly employed treatment for syphilis in the 15th to early 20th centuries in Europe. However, debate persists about whether it 'killed or cured'. Various medical historians have questioned whether mercury ameliorated infection or instead exacerbated it, even leading to debility and death. This has led some to claim that “the use of mercury in the treatment of syphilis may have been the most colossal hoax ever perpetrated in a profession which has never been free of hoaxes.” As no in vitro studies on the effectiveness of mercury treatments exist, we analyzed several skeletal samples from 17th to 19th century London for evidence of mercury treatments using portable X-Ray Florescence spectrometry (pXRF). Mercury concentrations were characterized in a pathological sample of skeletons manifesting lesions suggestive of and specific to syphilis (N=22). To establish background, endogenous exposure, a non-pathological control sample (N=51) of skeletons spatially, chronologically, and socioeconomically matched to their pathological peers was also assessed; soil samples (N=11) were analyzed to test for diagenetic transfer of mercury. Mercury concentrations were assessed in relation to the severity of syphilitic lesions, skeletal stress indicators, and mortality profiles to investigate whether mercury produced more positive or poisonous effects.

Pendergast, David [72] see Mayfield, Tracie

Peniche May, Nancy (UCSD) and Jaime Awe (Institute of Archaeology - Belize) [252], Buried like a Tick: A Middle Preclassic Residency beneath Plaza B, Cahal Pech, Belize

The earliest occupations in the Maya Area have aroused a great interest in the archaeological world. Investigations at several sites across the Maya lowlands (i.e. Tikal in the Peten, Komchen and Xocnaceh in the northern lowlands, and Xunantunich, Pacbitun, Cuello in Belize) have enable us to learn more about the sociopolitical development in the Maya society during the Preclassic era. Yet many aspects about the quotidian life of the earlier inhabitants need to be further explored to understand local and
regional variability. Recent excavations at the southern section of Plaza B at Cahal Pech (Belize Valley) have offered an excellent opportunity to investigate a Middle Preclassic residency (Feature 27) that reveals new information about the nature and scope of the different activities conducted by its occupants and the status these persons held in society. This knowledge, along with the information coming from other areas of Cahal Pech and other Belize Valley sites, will provide a better understanding of the household patterning and variability as well the sociopolitical and economic organization prevailing during the Middle Preclassic period in this region of the Maya area.

Peraza, Carlos [52] see Russell, Bradley

Pereira, Gregory (CNRS-Université de Paris I)
According to ethnohistoric documents, the Middle Postclassic period, which precedes the emergence of both the Mexica and Tarascan empires in Western and Central Mesoamerica, is characterized by instability, both political (fragmentation, competition, alliances and conflicts) and demographic (migrations, fast cycles of aggregation and disintegration or abandonment). Archaeologically, this period of Mesoamerican history is also marked by the establishment of large urban settlements that seem to reflect, in a material aspect, the migrations evoked in the texts. However, the study and comprehension of these migration processes is challenging due to the nature of the sources available. Precise knowledge of chronology, settlement formation processes, and occupation length is critical for appreciating the complexity of these phenomena. We base our research on sites located in the Zacapu region of Michoacan, attempting to identify the parameters most likely to shed light on the occupation history and formation processes of those ancient agglomerations. We consider several factors in the Zacapu settlements: radiometric dates, stratigraphy, waste and burials accumulations, as well as urbanism and spatial organization at the sites. Finally, we discuss our preliminary results in relation to current understanding of the studied social phenomena.

[116]  *Testing the Impact of Coastal Environments in Social Inequality through Lithic Raw Materials*
Archaeological sites and sources of lithic raw materials are fixed points on the landscape. Because of that, changes seen in the frequency of these resources in the archaeological record are usually related with visibility, availability, cultural and technological factors. Recent studies have highlighted the impact that the coastal settling has on social organization, complexity and inequality. Muge is an inland river valley that faced an oceanic environment during the period between the 8.2 ka event and the rise of Neolithic. This makes the Mesolithic occupations in this region crucial to understand the impact of coastal adaptations on social complexity. In this paper we present a high-resolution intra-site study of the lithic raw materials in Cabeço da Amoreira in order to test for the existence of such complexity and bring important insights to the issue of social inequality among hunter-gatherers.

[192]  *Shellfishing Does Not Equal Starvation: Debunking Modern Biases against an Ancient Lifeway in Tennessee*
There is a long-held bias among archaeologists regarding the role of shellfish in the diets of precolumbian North Americans. Despite presenting an easily accessible and nutritionally beneficial resource, shellfish have been traditionally viewed as a marginal food source consumed in response to starvation or environmental crisis. This bias stems from the emphasis on dietary protein sources during the heyday of Processualism, the supplemental role of shellfish and their association with women and children in modern and ethnographic gathering-collecting cultures, and the lack of large quantitative datasets on such sites that allow us to look at longterm
occupations. Recent surveys and excavations of shellfish-bearing sites along the Middle Cumberland River in Tennessee have yielded temporal and spatial data that allow us to reevaluate the role of shellfishing in the lifeways of people occupying these sites from the middle to late Archaic through Mississippian periods.

Quarrying, Site Fabric and Site Use in the First Millennium Menorca, Spain

The island of Menorca, Spain, hosted the development of the Talayotic Culture in the first millennium BC. During this period, the landscape was transformed by the construction of megalithic structures, both for public buildings –watchtowers and sanctuaries- as well as private buildings –domestic spaces, storage areas. These striking features have been extensively studied in recent decades. Some important archaeological projects have been carried out in buildings, dealing primarily with the architecture and the objects found in them. Interestingly enough, although all these structures are built with a specific local limestone, there has been very little attention paid to the provenance of raw materials and quarrying techniques. A similar lack of interest applies to the inter-building spaces in the settlements or non-architectural environments. These 'inter-architectural' areas have wonderful potential for understanding the complete fabric of the living space and can serve to weld activities within individual dwelling spaces to communal areas. In this poster we present some initial results of our excavations at Torre d’en Galmés, Menorca, that contribute to a greater understanding of the large site complex as a whole, quarrying and building methods specifically, and how all this relates to other sites in the Balearic Islands.

Proyecto Arqueológico Regional de Añasco: New Findings and Regional Research Trajectories in Western Puerto Rico

The west coast of Puerto Rico remains understudied in comparison to other regions of the island despite
the fact that historical documentation and previous, albeit limited, archaeological research suggest substantive pre-colonial and historic occupation of the region. In this research we present an overview and results of a recent field survey in the Añasco drainage basin in western Puerto Rico, including: 1) a regional predictive model for site location potential, 2) the results of preliminary regional walkover and subsurface testing, and 3) findings from the first season of excavations at a newly located Ceramic Age site. On one level, these findings support the potential of future archaeological study and generally validate the proposed field methods. Furthermore, these preliminary data suggest and/or confirm: 1) a possibility of Archaic inhabitation, 2) the involvement of the region’s Ceramic Age inhabitants in island-wide and inter-island exchange networks, 3) evidence for an early Historic (contact period) Spanish presence, and 4) intriguing patterns of 18th/19th century socio-economic processes.

[336] Evidence for production Practices, Artifact Arrangements and Postmortem Rites at the Paracas Necropolis Based on Patterns Of Fiber Deterioration

Since 2005, Peruvian and international researchers have worked to restore contextual information and restudy the components of ‘Paracas Necropolis’ mortuary bundles excavated in 1927-28 at the Necropolis of Wari Kayan at the Paracas site, under the direction of Julio C. Tello. For four years the project “Practice in Life, Presence after Death: Style and Substance at the Paracas Necropolis” has reconstructed gravelots and analyzed the form and material composition of the associated artifacts, in order to develop proposals on social identities and relationships asserted in continuing interaction between the living and the dead. Crossing archival data with analysis of textiles and other fiber-based artifacts that structure and adorn an ancestral effigy built around the remains of an individual, new types of information emerge that shed light on production processes and mortuary ritual. We have defined types of information provided by patterns of fiber destruction, including dye technologies, prior use of artifacts, their arrangement in the mortuary bundle, and previously unidentified practices that formed part of the funerary and ancestral rites.

[71] Integrating Local Perspectives: An Early Neolithic Case from Southern Jordan

The early Neolithic of southern Jordan provides a case study for how local, contextual approaches can shed light on agropastoral developments in Southwest Asia. Several Neolithic excavation projects and land-use studies in the Wadi al-Hasa of Jordan provide significant data sets. Localized spatial patterning of material culture, architecture, mortuary practices, and botanical remains suggest that decision-making and social interaction took place at sub-regional scales that overlapped in complex ways. This diversity suggests that local populations chose to adopt, ignore or modify different aspects of regional practice. Certainly the mosaic Early Holocene environmental and climatic conditions played a role. Understanding a phenomenon as multifaceted as the rise of domestication economies benefits from multi-scalar approaches that integrate local patterns into larger modelling efforts.

[144] Something Different within Casas Grades lithic Technology: New Finding from Small Sites in Casas Grades, Chihuahua Mexico

This paper reports on findings from the analysis on lithic collections from four Medio period small sites uncovered during the 2013 summer excavations in the Casas Grades region of Chihuahua Mexico. While prior excavations within the region have placed focus on the large and medium sized site types found throughout the region, the summer 2013 excavations focused solely upon the small, lesser-understood sites in order to evaluate their relation both specially and temporally to the rest of the area including the large site of Paquimé. Analysis of the lithic from these small sites revealed there to be a different strategy for the organizing of their lithic technology that was separate from that found at the other two site types. Such findings indicate a change within the selection of specific behavioral strategies the occupants where acting upon that may reveal more information as to what role these small sites played within the larger known Casas Grades interaction sphere.
Many years of excavations at multiple sites in Pennsylvania’s Susquehanna Valley have produced an overwhelming amount of burial data. This data set is believed to contain substantial information about multiple cultures, such as the Shenks Ferry and Susquehannock occupants of the same sites in virtually the same time period. The sheer volume of data, however, has precluded traditional straightforward analyses, hindering our ability to recognize patterns that may reveal details on how the two groups interacted. Multivariate statistical analyses provide an opportunity to look for such patterns. Rather than basing the cultural classification of a burial on a single variable such as body position, as has been done with the Shenks Ferry (extended) and Susquehannock (flexed), statistical analysis allows us to visualize multiple types of burials by determining other important variables and principal components (i.e., the typical burial of an adult male or female of the Shenks Ferry culture). The results provide alternate means for testing hypotheses about Shenks Ferry and Susquehannock cultural interaction and culture change. Such region-wide analysis could be expanded to assess interaction with other groups, to further test theories of culture change, and possibly to assist with determinations of cultural affiliation for repatriation.

Ripley Bullen defined the Bolen projectile point in 1958, but since then most of the ensuing archeological evidence regarding this Early Archaic phenomenon has been limited to surface finds. Recently, several sites with intact Bolen components have been excavated professionally and subsequently reported. One of these sites, 8LE2105, contained two stratigraphically separate Bolen components with a pooled mean average two date of 11,273 cal BP (9870+38 14C). This site provides new data that allow exploration of lithic technologies and site use. Considered in the context of data collected from other Bolen sites in north Florida, this information provides a more robust understanding of the Bolen toolkit, technological change, and settlement of hunter-gatherer adaptations at the onset of modern climates.

2D+ Full Coverage archaeological survey is often labor intensive and time consuming, especially in areas with dense architectural remains. LiDAR is fast becoming a powerful alternative to traditional surveying and mapping of archaeological settlements and cultural landscapes. This paper will explore the use of LiDAR derived 2D+ point clouds and hillshade models created from the point clouds to identify individual architectural features at the ancient urban center of Angamuco, Michoacán, Mexico. We present a comparison of methods to delineate and identify ancient features which range from visual interpretation of 2D+ point clouds and hillshades to the innovative use of object based classification techniques applied to products created from point cloud data.

Pfeiffer, Susan (University of Toronto) and Elizabeth Sawchuk (University of Toronto) [186] Funerary Practices in the West Turkana Pillar Sites: Evidence from the Burials Excavations at West Turkana pillar sites in 2012 and 2013 provide substantial information about the funerary uses of these sites. The Lothagam North site is the primary source of information (GeJi9, MNI=25), with corroboration from Lothagam West (GeJi10, MNI=3) and Manemanya (GcJh5, MNI=2). Most burials are primary interments, with newborn to old age and both sexes represented. Most bodies seem to have been demarcated by boulders or rock slabs on top of the head. Body positions are variable, but tight leg flexion and arms flexed so that hands are beneath the chin is the most common. Orientation of the body is variable, by cardinal direction and plane. Most people were buried with ornamentation, but grave gifts are rare. The density of burials at the Lothagam North site contributes information about site formation. Juveniles tend to have been buried less deeply than most adults were, bodies were close to one another, yet there is minimal evidence of the disruption of prior burials by subsequent interments. Such information from burials can inform broader questions of site formation and the status of those buried therein.

Phelps, Danielle (University of Arizona) and James T. Watson (Arizona State Museum, University of Arizona) [43] Bad Death or Blood Feud? Mortuary Performance and Signaling among Early Farming Communities in the Sonoran Desert Early Agricultural period (circa 2100 B.C. - A.D. 50) sites represent the earliest permanent village settlements based on agricultural investment in the southwest U.S. and northwest Mexico. Members of irrigation-based communities located on floodplains likely experienced considerable social tensions generated by balancing public cooperation for the management and maintenance of irrigation systems and private property interests among households controlling agricultural fields. The performance of normative mortuary ritual functioned to publicly integrate a shared community identity while simultaneously legitimizing household interests through descent and inheritance. However, several interments fall outside normative residues of mortuary ritual performance and instead likely correspond to "body disposals." These deviant burials could represent prescribed mortuary treatment for "bad deaths," or could have resulted from violent acts such as revenge killings—a form of costly signaling that results in the deposition and desecration of individuals by the perpetrators of such violence. These actions influence and manipulate an intended audience similar to premeditated mortuary performance, but they represent basal violent reactions (in that details are less premeditated) possibly stemming from blood feuds that result in costly signaling. The resulting action can be ‘costly’ because of the potential it creates for inviting reprisal from the kin/community of the deceased.

Phillips, Paige (The University of South Florida) [140] Examining Activity Organization through Geochemical Analysis at Tlalancaleca, Puebla, Mexico (800 BC-AD 100) This poster presents the results of a geochemical investigation of soils and sediments from Tlalancaleca (ca. 800 BC to AD 100), a large urban center in the Puebla Valley of the central Mexican highlands. The main ceremonial center in the site center, the Cerro Grande Complex, was cored in 2013, providing over 500 soil and sediment samples from Formative occupation surfaces. The samples were subjected to geochemical analysis, including pH, Mehlich phosphate colorimetry, and a series of tests for organic residues developed by Luis Barba. Select samples were also characterized using Inductively Coupled
Plasma-Mass Spectrometry to examine a broad suite of elemental concentrations for correlation with human activity patterns during the period of Tlalancaleca’s occupation. In understanding the chemical residues in the plazas and terraces within the complex of Cerro Grande, the activities of these areas and thus the uses of these spaces have come to light, revealing the social and political dynamics of space at the Cerro Grande complex and larger site of Tlalancaleca.

[277] Mapping the Underworld: Innovations in Cave Mapping at Las Cuevas Using GIS
Maps are abstractions of the real world that are essentially arguments for a particular view of a space. Cave surveys conducted by archaeologists and those of spelunkers are necessarily different and no cave map will be identical to another. Therefore, it is not surprising that to understand and render caves from their perspective, archaeologists must develop their own cave survey methods. Cavers traditionally survey natural caves using compasses, clinometers and more recently distometers, moving from “station to station.” A sketch map is generated in the field and some distances are measured, but this is not always systematic. Total stations or other heavy digital equipment is rarely employed because of obvious access issues in many caves. At Las Cuevas we needed to develop a hybrid form of cave mapping demanding very high accuracy in some areas. We employed traditional cave survey techniques making hand-drawn maps using compass, clinometer, and distometers, with digital technologies to increase our level of accuracy yet retain the detail of recording that only hand-drawn maps can offer. Using GIS as a tool in this process we were able to produce maps that are both visually informative and capable of managing and analyzing our data.

[327] Three Models for Social Contexts of the Production and Use of Moundville’s Hemphill-Style Engraved Pottery
This paper evaluates three models that have been proposed for social contexts of the production and use of Hemphill-style engraved pottery within the Moundville polity. Moundville is a major Mississippian center located in west central Alabama with 32 earthen mounds. There are an additional 15 single mound centers within the polity located along the Black Warrior River. The Hemphill style is Moundville's local representational art style that can be found in several genres including stone palettes, copper gorgets, shell gorgets, stone pendants, as well as engraved and incised pottery. This paper focuses only on the engraved pottery (ca. AD 1325-1450) as it seems likely that the social contexts of the production and use of the various genres may be different. The political economy model, the sacred economy model, and the associations model will be evaluated based on stylistic evidence, usewear, and distribution.

[153] Bioarchaeological Analysis of Cusirisna Cave, Nicaragua
There is little archaeological data regarding the prehistory of central Nicaragua, especially in reference to mortuary practice and the use of caves. We analyzed human remains and artifacts from Cusirisna Cave, Boaco, collected in the 1870s by Dr. Earl Flint, an explorer for the Harvard Peabody Museum with the goal of understanding mortuary practice and the function of Cusirisna Cave through a bioarchaeological lens. The study of the commingled osteological remains (n=82) established MNI (=9); estimated sex, age, and stature; identified pathology and trauma; and examination of cranial modification for the purpose of studying ethnic affiliation. The associated artifact assemblage included shell and greenstone beads, guacales (bowls made from jícaras), and a well-preserved wooden duho. A radiocarbon assay using the accelerator mass spectrometry technique on a sample from one of the guacales yielded a date of cal A.D. 1450 with a 2-sigma calibrated interval (95% probability) of Cal AD 1430 to 1483 (Cal BP 520 to 470) (Beta-315973). The late date provides an opportunity to interpret the remains in light of the available ethnohistorical evidence from the region, specifically using skeletal remains and context to understand ritual practice in a Nicaraguan cave.

[340] A Diachronic Analysis of Floral Remains at Aztalan, a Multicomponent Late Prehistoric Site in Jefferson County, Wisconsin
The Aztalan site is a heavily fortified Late Prehistoric village in southeast Wisconsin. Excavations in 1984
in the riverbank midden revealed a complex stratigraphic profile with evidence for an initial Late Woodland component followed by a mixed Late Woodland/Middle Mississippian occupation. A diachronic paleoethnobotanical analysis of these components is presented alongside data recovered during the 2011 field season from a probable early Mississippian context. Analysis suggests similar patterns of wild and domesticated plant use for both components, although overall taxa diversity is low. New direct AMS dates on Zea mays specimens prompt a discussion on the possibility of cross-contamination at a multicomponent site.

"Toss of the Dice:" Gaming Pieces in Middle Missouri Archaeology

Gaming pieces and gambling practices have figured prominently in discourse within economic anthropology and in describing exchange systems in North American archaeology. A review of Mandan, Hidatsa, and Arikara ethnography and history suggests the importance of gambling behavior for nineteenth century Plains Villager exchange systems. The Middle Missouri archaeological record provides the opportunity to examine the material correlates of gaming practices from the longue durée. Examples drawn from archaeological and ethnographic collections are analyzed with respect to style horizons, intertribal relations, and pre-contact and post-contact exchange systems for the Northern Great Plains.

Pickering, Robert (Gilcrease Museum/University of Tulsa)

Results of External and Internal Examinations of the Human Figures from Shaft Tombs

The finely crafted hollow ceramic figures from West Mexico have been recognized for their visual appeal for over a century. These figures spurred waves of looting and generations of people creating replicas. Many figures and entire collections have been donated to museums with minimal contextual data. Reaction to such collections often falls into two disparate responses; either the objects are assumed to be genuine because they are in a museum or since they have minimal data, the figures are deemed to have no significant research value. This project explores the premise that museum collections of Occidente figures do have research value that is revealed through detailed internal and external examinations. The first goal of this research is to create a system of objective and reproducible observations for determining authenticity. Work has primarily focused on observing mineral deposits and insect puparia. Observations of the internal surfaces of figures with a medical endoscope and CT scanning equipment dramatically enhance the ability to find indicators of authenticity. These observations partially recontextualize the figures so that they can become part of the second and most critical objective of this project - to understand the use and meaning of hollow ceramic shaft tomb figures.

Obsidian Source Frequencies as a Social Attribute at San Felipe Aztatán, Nayarit, Mexico

This research uses a combination of color sorting and XRF geochemical sourcing to identify patterns in volcanic sources of obsidian artifacts at Postclassic-period San Felipe Aztatán in Nayarit, Mexico. Despite nearby sources being easily accessible, more sophisticated lithic reduction techniques seem to have been used only for more distant sources. With no substantial qualitative differences between obsidian sources, purely social factors likely resulted in the temporal and spatial distribution patterns at San Felipe Aztatán. I argue that the restricted access to distant sources, such as Pachuca, created elevated value of obsidian blades and thus created, maintained and legitimated elite identities. At San Felipe Aztatán, the limited area in which Pachuca obsidian is found may indicate an area of elite residence or elite activity, while its limited temporal distribution may reflect the peak of trade and influence of the Aztatlán tradition before the expanding Tarascan Empire. This research may have greater application for other sites within the Aztatlán tradition. If obsidian source can be utilized to identify social stratification, we may be able to understand the spatial and social organization of specific sites as well as the complex dynamic trading relationships between sites.

Production, Consumption and Visuality: Abundance and Chinese Porcelain, 1350-1800

Chinese porcelain was and is characterized by abundance in production, consumption, decoration and function. In China, from about 1300 porcelains were made at Jingdezhen for domestic and foreign consumption, utilizing large quantities of raw materials, labour and energy. The evidence of abundance is visible today in the huge sherd heaps at the imperial kilns, the textual records of vast
orders for specific occasions and the deforestation of whole areas of south China. Visually, porcelain in China further demonstrated a cultural desire for representations of abundance through the often dense and repetitive decoration that can be seen on Chinese porcelains from the 14th century onward. For foreign consumers, the development of maritime trade from as early as the Tang dynasty ensured that they too could also acquire and use large quantities of Chinese porcelain. Abundance is therefore an important framework for the understanding of key characteristics of the character and impact of Chinese porcelain domestically and overseas. With a view to exploring this new way of looking at Chinese porcelain, this paper will consider manifestations of abundance in three different contexts: a Yuan dynasty dish, the Ming imperial factory, and a Qing dynasty shipwreck.

[25] Human Cranial Masks from Central Mexico: Techniques and Usage
This study focuses on five cranial human masks from Postclassic central Mexico. Four belong to two children and two adult males found in two offerings at Templo Mayor. The fifth adult male mask was found in Tlatelolco among 100 skulls belonging to a tzompantli or skull rack. This latter mask is less ornate than the ones found in Templo Mayor, it is also lacking eyes shells and knives in mouth. Here we analyze, explain and discuss the techniques (cut marks, impacts, bone cutting, and pigmentation, among others) employed to elaborate such masks. We also discuss the evidence of repetitive usage of one of these masks in several ritual occasions. This investigation contributes to the knowledge of relevant ritual elements to the cosmovisión of the central part of ancient Mexico.

Pikirayi, Innocent
[145] The Post-Great Zimbabwe city: Towns, Palaces, Villages, and Functional Specialization in the Mutapa State, Northern Zimbabwe, 1500-1900 AD
Some Portuguese written sources referring to southern Zambezia – the region dominated by the Zambezi River – describe capitals of the Mutapa State variously as “...of stone and clay and very large...” or composed of “...many houses of wood and straw.” In one of the towns, the residence of the king is described as “...a very large place, whence the merchants take to Sofala gold which they give to the Moors without weighing for coloured cloths and beads which among them are most valued...” (Theal, 1898–1903, vol. 1, 95-6). It is evident from both archaeological and available written sources that although population aggregation continued in northern Zimbabwe in towns akin to the extant Great Zimbabwe, the gradual disappearance of ‘elite’ stone-walled palaces signified the demise of the much earlier classical city. Socio-political complexity continued in different forms, however, with functional and other specialization taking place within villages contiguous to and beyond palaces.

Pilles, Peter and Kimberly Spurr (Museum of Northern Arizona)
Human burials recovered from Coconino National Forest land during the last century are being documented prior to repatriation under NAGPRA. Working with tribal consultants, we have developed a documentation regimen to provide information about prehistoric demography, health, and skeletal traits that indicate genetic relationships within and among cultural groups across the Southwest. Our goal is to evaluate and expand models of ancestral migrations and interactions that are of interest to tribal members and archaeologists, and to expand our understanding of Southwestern human history. Our work to date suggests that patterns of morphology in human remains that reflect genetic relationships may be mirrored by distinctive characteristics of ceramic vessels from the same sites, possibly indicating the presence and movement of cultural subgroups such as families or clans.

Pilliard, Sarah (Stony Brook University)
[186] Stone Tools on the Moving Frontier: Lithic Technology and Early Herding in Northwest Kenya
The prehistoric spread of food production was associated with changing social organization as early
farmers and herdsmen negotiated new environments, new subsistence bases, and new groups of people. In the Turkana Basin, Kenya, where herding was the first form of food production, early pastoralism may be linked to the creation of monumental architecture. Around 4000 bp, contemporary with the earliest livestock in the Turkana Basin, people constructed ‘pillar sites’ containing burials, stone platforms, and basalt pillars. Analysis of lithics from the 2012 excavations of four West Turkana pillar sites shows how they were used for short-term, specialized purposes, whereas other contemporary sites were used for longer durations. Pillar site lithic assemblages can also clarify whether these sites were constructed by one or multiple groups of people on the landscape. This case study elucidates the ‘frontier zone’ of food production in which there may have been a mosaic of different cultural groups dealing with a novel social landscape.

Pilloud, Marin and Clark Larsen (The Ohio State University, Columbus, OH)

[291] Alternative Definitions of Kin within Bioarchaeology: A Case Study from Neolithic Çatalhöyük, Turkey

Within bioarchaeological research, kinship has been studied through biodistance analyses that identify patterns of biological relatedness within a skeletal sample. As a stand-alone method, this approach assumes that kinship is biologically defined. However, kinship is a much more complex social unifier, extending well beyond the biological realm. It is therefore important to explore possible alternative definitions of kin in past societies utilizing human remains within archaeological contexts. Using dental data from Neolithic Çatalhöyük, Turkey, a biodistance analysis was undertaken to explore biological patterns in relation to interment location (subfloor house burials). A biological division was identified at a large community level; however, meaningful patterns were not identified at the individual level. Based on these results, we argue that this early farming community was largely not biologically structured at the household and neighborhood level. Instead, we draw from the wealth of archaeological data to argue that social structure was likely fluid and complex, depending on any number of factors, including house residence, food production, social bonds, ideological views, and to a lesser extent, biological affinity. This study highlights the need for a connection of human biological and archaeological data for developing a more informed understanding of kinship in the past.

[287] Obsidian Projectile Points: Patterns of Variation and Range of Mobility during the Mid-Holocene in the Salt Puna of NW Argentina, South-Central Andes

Although projectile points have dominated the discussion of Paleoindian archaeology in North and South America, this tool class has not figured prominently in the archaeology of hunter-gatherers of the South-Central Andes. Here we present a typological, technological and morphological analysis of obsidian, quartzite and vulcanite projectile points found in Antofagasta de la Sierra, Catamarca. We compare projectile points from tightly dated Middle Holocene contexts and investigate patterns of technological, morphological and stylistic variation between projectile points manufactured of local and non-local raw materials. Geochemical source identification is used to draw general archaeological implications regarding wide mobility range that includes the use of five obsidian sources distant 30-120 km.

Pinto Lima, Helena (Universidade do Estado do Amazonas - Brazil)

[331] Archaeology and Traditional Communities in Amazonia

Archaeological sites in the Amazon are generally composed of anthropogenic black soils and ceramics found in locations that are re-inhabited by contemporary communities. This is due to chance but also punctuated by a series of elements of cultural choices which are repeated over time. Thus, archaeological materials are, in a way, part of daily riverine life. Archaeologists have looked towards contemporary societies to understand not only aspects related to past societies, but also to better frame social interactions in the present. In this way archaeology is not just a way to understand the past, but also a social practice experienced in the present. Present-day riverine communities constitute a privileged object of study in the practice of Amazonian archaeology. Their (re)signification of the place where they live and its spatial and material components are important elements that contribute to a more holistic understanding of interactions between community and the archaeological record, in a process of continuous formation.
ABSTRACTS OF THE SAA 79TH ANNUAL MEETING 598

and transformation of the archaeological site. Through archaeological approaches that allow for a broader dialogue and multivocality that interrelates different spheres of knowledge, including traditional and scientific knowledge, Amazonian societies are themselves actors that contribute to the construction of archaeological knowledge.

The Production and Use of Ropes in the Early Neolithic Site of La Draga (Banyoles, Spain)

La Draga is an Early Neolithic site located on the shore of Lake Banyoles (Spain). The archaeological layer of the earliest phase of occupation, dated to 5,300-4,900 cal BC, has been preserved in waterlogged conditions. Several fragments of ropes have been preserved in the site, providing a unique example of rope production by the early farmers in the Western Mediterranean region. The objective of this work is to present the types of ropes recovered at the site. Several ropes made of vegetal twisted fibres and some made of lianas show the diversity of rope production. This paper presents a discussion of rope production and examines the potential uses of these items.

Pirtle, Jennifer (The University of Tulsa)

Gender, Age, and Status in Ancient West Mexican Figurines Through the Lens of Body Modification

The Mexican states of Nayarit, Jalisco, and Colima comprise most of the area in which the so-called shaft tomb culture flourished circa 300 BCE to 300 CE. The most distinguishable grave goods found within these tombs are ceramic figurines that are thought to represent the people themselves, rather than deities or deity-impersonators. Based upon this hypothesis, this paper investigates attributes of gender, age, and status in Ancient West Mexico by means of identifying and analyzing body modification and adornment as viewed on the ceramic figurines. Unfortunately, research in the Occidente has suffered from extensive looting and widespread production of modern copies. To counter these negative effects, recent research into authenticity of individual figurines will be used to verify that only genuine features are considered. Various physical representations on the figurines, such as tattooing, piercing, body painting, and cranial deformation, will be identified and statistically analyzed in order to discern their connection to gender, age, and status.

Inferring Sociopolitical Dynamics in the Moquegua Valley through Geochemical Analysis

This paper presents the first synthesis of available geochemical data from the Moquegua Valley in southern Peru. LA-ICP-MS analysis has been conducted on raw clay sources from the lower, middle, and upper portions of the valley. Additional geochemical analysis has been performed on ceramic samples collected from Middle Horizon (500-1,000 A.D.) through Late Horizon (1,450-1,532 A.D.) sites in the Moquegua Valley. These comprehensive data allow for a broad characterization of social interaction among groups inhabiting the region for over a millennium. Furthermore, the information gleaned from geochemical analysis forms the basis for an ongoing effort to answer important anthropological questions. More specifically, this research is helping to understand ceramic production and distribution among prehistoric Andean communities, to elucidate interactions between ethnic groups, and to infer socio-political dynamics throughout several periods of dramatic cultural transformations.

Pitblado, Bonnie (University of Oklahoma)  
[69]  Earlier and Higher than You Thought: The Peopling of the Rocky Mountains  
We’ve all heard the cliched response to why one climbs a mountain: “because it’s there.” Yet recently gathered evidence indicates that First Americans occupied the Rocky Mountains just as soon as alpine glacial melting allowed. The archaeological signature they left behind is inconsistent with merely traveling over or through the Rockies to move from some relatively flat “Point A” to another relatively flat “Point B.” Instead, the signature suggests sustained use of the Rockies very early in the continental peopling process. Clearly, the motivation(s) for terminal Pleistocene colonization of the Rocky Mountains extended well beyond “because they were there.”

In this paper I explore three inter-related topics. I first discuss the unique ecological structure and resource base of the Rocky Mountains—particularly when compared to the archaeologically better-known adjacent Plains and Far West—highlighting why we should expect prehistoric people to have been drawn to them. Next, I overview the time frame for initial colonization of the Rockies, touching on the variability in occupation dates as one moves north/south. Finally, I discuss what extant archaeological evidence suggests about how, precisely, First Americans exploited the heterogeneous Rocky Mountain landscape.

Pittman, Holly (University of Pennsylvania)  
[329]  Glyptic Art in the Uruk Expansion: Measuring Interaction and Differentiation through Imagery  
The late fourth millennium BCE drainage basin of the Tigris and Euphrates Rivers saw the introduction of material forms, known under the rubric of Middle and Late Uruk and originating in the lowlands, into strategically located sites in the Jezira steppe zone of upper Mesopotamia. This contribution characterizes and evaluates the visual evidence, both iconographic and stylistic, preserved as impressions of cylinder and stamp seals on clay devices used in the administration of goods and labor. It is argued that this imagery and style originates in Khuzistan emerging out of a long tradition of economic administrative practice centered around figural and abstract imagery impressed on anepigraphic documents and clay closing devices. A comparison of the iconographic repertory of images from Uruk and Susa/Chogha Mish suggests that distinct sectors of the economy were administered in the two zones of the lowlands. An extended comparison that includes imagery from sites across the Uruk diaspora deepens our grasp of the motivations for the expansion and the diverse character of the colonies and their relation to the substrate Late Chalcolithic communities.

Placzek, Christa (James Cook University) and Peter Veth (University of West Australia)  
[244]  Climate Reconstructions from Barrow Island Speleothems  
Cave carbonates are proven archives of terrestrial climate variation. Indeed, such records are among the most useful records of past climate as the chemical proxy data preserved in carbonates evidence changes in rainfall, mean temperature, and surface vegetation data at high resolution. Climate records from cave carbonates are unique in that they are high resolution, generating snapshots of palaeoclimate that can be used to greatly refine the more generalized climate records preserved by sediments and fossils of the time. Cave carbonates can also be dated radiometrically using U-Th methods to provide robust chronologies, providing some of the best age control for past climate changes. Two large subterranean caves with speleothems are located on Barrow Island, providing opportunities for climatic reconstruction from cave carbonates. Development of these climate archives will offer insights into climate that is directly applicable to the human occupation history of the site. The potential of Barrow Island to provide both a recent a deep-time perspective on tropical/subtropical climate variability suggest that it will add to critical understanding of the local, regional, and global drivers of climate change.

**[305]** *Two Thousand Years of Ceramics along the Uci-Cansahcab Sacbe*

Three seasons of excavation at Maya sites in the region of the Uci-Cansahcab sacbe in northwest Yucatan, Mexico have produced a corpus of ceramic material that spans the Middle Preclassic through the Colonial periods. This paper outlines the results of the first stage of analysis, which permit us to 1) sketch the chronology of the population foci of Uci, Kancab, and Ucanha, as well as of surrounding low-density but continuous rural settlement; 2) discuss the dynamics of shifting regional affiliations over a span of 2,000 years; and 3) contribute to a larger regional conversation about at least two current problematics. First, materials from the site of Kancab, in particular, address the issue of pre-Mamom ceramics in northwest Yucatan. Second, ceramics from multiple locales in the Uci-Cansahcab environs allow us to approach the fuzzy trajectory of the evolution of red-slipped wares between the Late Preclassic and Early Classic periods in this region.

**Plannette, Carol**

**[174]** *Space Defined: Mortuary Analysis and the Symbolic Depiction of Spatial Organization.*

Archaeologists have long been interested in the relationships that form the burial rites and rituals in the Andean region. As a result, an important consideration to the analysis of mortuary practices is the utilization of the landscape and space. Various pre-Columbian cultures have been known to allocate unique spaces for the interment of their dead. These chosen burial landscapes, whether generated from a natural terrain or manufactured, create a symbolic representation of the culture’s relationship with the land and their ancestors. There remain, however, numerous issues to be resolved, including the dynamics of the sociocultural relationships of the Moche people of the north coast. The application of landscape analysis to specific Moche burial grounds provides useful opportunities to reexamine various factors regarding the cultural symbolism and identity of the people associated with the burial areas. This poster focuses on the opportunities provided by landscape analysis to discuss the Moche’s arrangement of burial space in a new framework, providing insight into the sociocultural relationships of their mortuary practices, ancestor veneration, and their everyday lives.

**[322]** *Digital Preservation Approaches for Legacy Archaeological Collections*

Archaeology is faced with the inheritance problem of managing legacy collections, partly due to the high expense of maintaining such collections. Often these datasets are underutilized and difficult to properly preserve or to integrate into the current archaeological dialogue. To address this problem, an examination of the current condition of the records and artifacts of legacy archaeological collections is needed. In this research, recursive archaeology and living documents will be used as guiding principles for a research design to integrate the Anasazi Origins Project (AOP) Legacy Archaeological Collection into the current archaeological dialogue using electronic databases such as a geodatabase. Traditional and digital preservation methods will be used and presented to construct a conceptual frame of reference for similar types of legacy archaeological collections. This research is an effort to preserve and disseminate the dataset that helped to define the Archaic northern Southwest of the United States, the Oshara Tradition.

**[215]** *When Scientific, Indigenous and Capitalist Epistemologies Collide - Investigating Heritage Conflicts and Repatriation in Contemporary Russia*

This paper explores the construction, contestation and appropriations of different post-Soviet heritages in the multi-cultural Altai Republic (federal subject of Russia). It particularly investigates the conflict surrounding the excavation, scientific investigation, and subsequent repatriation of a remarkably well-preserved frozen female mummy (named the Ice Maiden) found 20 years ago. The extent of this dispute is more than merely a story of two opposed approaches to cultural heritage; it is rooted in the specific sociopolitical background of archaeology and Indigenous rights in contemporary Russia and frames within the post-Soviet period of ethno-cultural cataclysm in which appropriation of heritage and history further expanded. By applying a relational social framework to social practice to the multiple, historically-embedded conceptualizations and appropriations of archaeological heritage I develop a multi-actor stewardship approach to Indigenous archaeology in Russia. The Ice Maiden case clearly presents archaeology as part of a broader holistic process, dominated by different actors with their own particular agendas and dispositions. Episodes of heritage contestation not only enable a comprehensive
understanding of Indigenous politics and archaeological ethics in contemporary Russia, but also present archaeological heritage as a social practice providing a unique information source on the dynamics of a transitional multi-cultural society.

Incised Stones from Idaho

Incised stones have been reported from locations across Idaho—most commonly in the panhandle region. Though relatively rare, they are in some instances associated with Late Archaic (2000-150 B.P.) period sites and in southeastern Idaho with the Fremont pattern. Five types have been described and include cobbles with small incisions along lateral margins, cobbles having centrally placed straight parallel lines, cobbles with centrally placed hachure, stones with irregular etchings, and highly decorative stones that combine a variety of motifs. This paper reviews the geographic and temporal distribution of incised stones in Idaho offering observations regarding their function.

Production, Exchange, and Complexity at Crystal River

Crystal River (8CI1) is a Middle and Late Woodland period (ca. 300 B.C. to A.D. 1050) site on Florida’s west-central coast. The site is famous for its distinctive monumental architecture and diverse suite of local and extra-local Hopewellian trade goods. Archaeologists have traditionally explained the site’s seemingly precocious complexity as a product of elite control of the production and exchange of whelk shell cups and ornaments. Recent work suggests a more heterarchical complexity with a less linear relationship to production and exchange. Craft production and exchange may have been—to an extent—centralized at Crystal River, but were diverse, small in scale, embedded in ritual, and dependent on relationships with communities elsewhere for raw materials and people. We argue that this centralization resulted from the interplay of ritual, economic, and ecological structures and the agency of elites who encouraged, but did not control, the process.

Tunics, Tapestries, and Gendered Bodies: Male- and Female-associated Clothing Sets from Tiwanaku Burials at Rio Muerto, Moquegua, Southern Peru

Gender is an important and inescapable facet of both individual identities and of the structures and functions of whole societies, yet is often difficult to parse out through the material record. The formation of gender identities and the nature of gender relations under the Andean Middle Horizon state societies are two of the least understood aspects of the Wari and Tiwanaku civilizations. Little is known about when, where and how gender identities were constructed, and how gendering fit into the larger process of socialization. In the case presented here, preservation conditions permit the contextual examination of clothing from individual, scientifically excavated burials from the Tiwanaku culture site of Rio Muerto (600-1000 A.D.). Using data from burial clothing as well as paleodemographic information about the individuals interred, the researchers have isolated a number of “outfits” that are particular to male and female individuals. Here we discuss the implications of the differences and similarities in these clothing sets, the clues this may hold to gender categories and boundaries, and how these societal constraints were enacted and reinforced through material culture worn on the body.

Lessons from Tetimpa: A Formative Village in Mexico’s Central

Fifteen years of fieldwork at the highland site of Tetimpa in Puebla, Mexico, have provided rich data sets that allow us to visualize both patterning and variation among the households of this large dispersed village that was occupied from the Middle to the Terminal Formative. Here we reflect on what these data from 27 houses reveal about social organization, storage technology, exchange networks, and domestic ritual at the village level during this time period.

Fluvial Deposition and El Niño at San José de Moro, Peru

In coastal Peru, the El Niño climate anomaly is a frequent cause of devastation and social disruption for
human populations. However, the prehistoric chronology of this phenomenon is poorly understood, limiting our understanding of the interrelationship of El Niño and the archaeological record. In this study we interpret an alluvial sedimentary sequence at the archaeological site at San José de Moro to infer patterns of past El Niño flooding. This location experiences flooding only during periods of El Niño rainfall due to the limited size of the Chamán River’s drainage basin and its coastal desert setting. The sedimentary sequence formed at the site is thus interpreted as a record of past El Niño flooding. Our detailed geologic analysis suggests changes in El Niño intensity over time. A major shift from broad, fine grained, floodplain deposits to higher energy, coarse grained, channelized deposits may indicate an increase in flood velocity at this site or a change in channel location related to increased flood discharges, both potentially caused by an increase in the strength of El Niño events. This climatically driven landscape change has significant implications for reconstruction of past climate patterns and the impact of this phenomenon on prehistoric humans.

Pohl, John (UCLA)
[339] Chicomoztoc as an Inter-Regional Exchange Zone
The legend of Chicomoztoc, is largely regarded by ethnohistorians as a mythic event by which Nahua populations accounted for their migration south into the Basin of Mexico and the Plain of Puebla under the leadership of Chichimec culture heroes who subsequently became the focus of religious cults established within their city-states. This examination of the “Seven Caves” is not so concerned with the myth itself or even the specific location but more importantly how it could have functioned as an intermediate frontier zone for cultural and economic exchange between the Casas Grandes, Aztatlan, and Huaxtec traditions.

Poirier, Marcela (Purdue University), Hendrik Van Gijseghem (Université de Montréal) and Kevin Vaughn (Purdue University)
[211] Hematite Mining and Ritual in Ancient Peru
We report on multiple seasons of excavation at Mina Primavera, a remarkably well-preserved hematite mine located in the Nasca region of the southern Peruvian coast. Remarkably well-preserved, it has yielded an impressive diversity of materials that include tools, ceramics, textiles, food remains, and items related to ritual. Evidence indicates that the principal extractive activities occurred in the first centuries AD by members of Nasca society. The place’s status and importance in the south coastal landscape appear to have changed through time, and it was sporadically visited and used for diverse reasons until the 20th century. This research takes advantage of a rare archaeological context and highlights the intersection of place, materiality, and landscape in its many dimensions.

[173] Use, Reuse and the Lifecycle of Earth Ovens on the Canadian Plateau: A Case Study from the White Rock Springs Site (EeRj 226), British Columbia
Archaeologists have often dated earth ovens/roasting pits used by Plateau collector communities for large-scale root processing on the basis of single radiocarbon sample per feature. Consequently, they treat oven construction and use as a “one off” event in discussions of root resource intensification. Using a series of 45 radiocarbon dates collected from various depositional zones of 10 roasting pit features at the White Rock Springs site (EeRj 226), British Columbia, we show that roasting pits have a complex life history of use, re-use, maintenance, and renovation. While roasting pit dimensions have been inferred to vary with respect to the quantity and type of plant materials processed and nature of the socioeconomic group, change in pit size over time is often cited as evidence of changing levels of overall root resource intensification. We argue that the re-use of roasting pit facilities is a significant factor in explaining size variation and requires archaeologists to rethink existing models of resource intensification.

Politis, Gustavo (INCUAPA-CONICET, Argentina)
[73] Signs in the Forest: Territorial Markers of the Tropical Forest Hunter-Gatherers of South America
Hunter-gathers of the tropical forest of South America conceive their territory in several dimensions.
However, the band or co-resident group territory is the one which is felt, perceived and used as the “closest” both in spatial and emotional terms. This land has been thus constructed for generations, and its texture has been transformed and modified, in a subtle way, through the centuries. Moreover, the band territory is also signaled by means of a variety of marks on the land: broken branches, animal bones, feathers, scratches in trees, etc. All these marks are saturated with coded information and contain different layers of meaning. The Nukak from the Colombian Amazon and the Hoti from the Upper Orinoco of Venezuela provide good examples to illustrate and explore these kinds of actions and to better understand the territorial behavior of tropical forest hunter-gatherers. In this paper, these issues will be presented and discussed and will be compared with similar information from other hunter-gatherers of South America such as the Ayoreo and the Hetá.

[340] Fort Ancient Ritual Poles
Large ritual poles are most commonly associated with plazas or central places within a community. Within these contexts, they may have served as marker posts or as symbols of community existence and identity. The rituals and ceremonies during which these poles were pulled and reset may have been as important to the community as the pole itself. In this paper, we explore the possibility that by ca. A.D. 1400 shorter ritual/sacred poles were being erected inside Fort Ancient public structures. We argue that the presence of these interior poles and their repeated resetting and capping represents a shift from rituals and ceremonies that were open to all, to ones that were restricted to a segment of the community.

Pollard, Helen (Michigan State University)

[254] Tula of the Toltecs and Tzintzuntzan of the Tarascans
Unlike other core regions of Mesoamerica central Michoacán did not have a long history of city-states and empires during the Classic and Early Postclassic periods (AD 200-1100), but was politically and economically peripheral to powerful polities to the east and west. However, in the last centuries before European Conquest a highly centralized state emerged in the Lake Pátzcuaro Basin, which was rapidly transformed into an expanding empire. The late emergence of the Tarascan state after AD 1350 and its survival into the early sixteenth century has provided us with the opportunity to use both archaeological and documentary sources of data. These sources present a complex, and somewhat counter-intuitive, pattern of ruling elites who claim an immigrant Chichimec heritage to justify their cooption of the native Purépecha nobility, while at the same time presenting themselves as fully ethnically purépecha. Moreover, they have materialized the state and its institutions using a template from the Toltec world of Epiclassic and Early Postclassic north-central Mexico. In the ecologically and politically unstable world of the Postclassic both commoners and elites alike apparently saw benefits in following this new form of society and internalizing it as the only true society they had ever known.

Pomédio, Chloé (archaeologist)

[200] The Incised Ceramics of Sayula Basin: An Interregional Perspective
The Sayula Project (UDG-INAH-IRD) allows us to study ceramic production in prehispanic times around the Sayula Basin. During the Classic and Epiclassic periods (Sayula Phase), Sayula and Atoyac incised types employ decorative techniques that are reminiscent of incised ceramics produced elsewhere in northwest Mesoamerica (i.e., Bajío, Michoacán, Jalisco, and Zacatecas regions). The technological study, related to the iconographic classification of the Sayula incised ceramics, permits us to understand some anthropological aspects of this specific tradition of ceramic production regarding the choices of potters. Thus, comparing the technological and iconographic attributes of Sayula and Atoyac incised types to similar traditions in neighboring areas should provide a clearer picture of the interregional relationships represented by these decorated ceramics.

Pomfret, James (Georgia DOT)
[196] Geophysical Investigation of Andersonville Cemetery
The Andersonville National Historic Site, located in southwest Georgia, is the site of the infamous Andersonville Civil War Prison. Over a period of 14 months the confederate prison held 45,000 union soldiers, of which nearly 13,000 died from starvation and disease. The prison cemetery is located adjacent to the prison and holds the remains of all who died at Andersonville Prison. Based on limited information from soldier diaries and prison records, it has been understood that the earliest part of the cemetery contained individual interments in wood coffins. As the number of dead increased, the burial methods changed from individual interments to mass burials in trenches. Using Ground Penetrating Radar, Resistivity, and Magnetometer, a geophysical survey was conducted in the prison cemetery in an effort to determine at what point during the 14 month history of the prison did the interment method change from individual burials in coffins to mass burials without coffins.

[279] Making Urban Places in the Late Formative Gulf Lowlands, Mexico
Cities are palimpsests. As a spatial and historical process, urbanization responds to perceived needs and aspirations of the moment as well as the physical and remembered imprint of the past. These points are well represented in the archaeological record of the southern and south-central Gulf lowlands of Mexico. While sharing a generally dispersed population pattern common to most lowland centers in Mesoamerica, Late Formative centers in this region exhibit impressive variation in nucleation, boundedness, monumentality, and the layouts of civic-ceremonial complexes. Grounded in our work in and around Tres Zapotes, Veracruz, but employing a comparative perspective, we argue that much of this variation results from politically strategic negotiations among factions and emergent classes and the reconciliation of differing politico-economic traditions with contemporaneous realities.

[206] Applied Zooarchaeology of the Late Holocene Freshwater Mussel Community in the Upper Trinity River of North Texas
Recent studies indicate that the late Holocene (approximately 2000 to 500 B.P.) freshwater mussel community in the Upper Trinity river of north Texas was more diverse in terms of species richness than the contemporary community. However, archaeomalacological data have been studied from only a handful of sites, some with small mussel assemblages. We report new data from 41TR198 a late Holocene site on the West Fork of the Trinity near Fort Worth. We analyze nestedness and species area curves to assess data quality to determine if the Upper Trinity faunas are representative of the late Holocene mussel community in terms of taxonomic composition. Results indicate that these applied zooarchaeological data provide an important conservation and restoration benchmark for the Upper Trinity river, which is a highly modified system due to reservoir impoundment, water use, and water treatment.

Popescu, Gabriel (SHESC, Arizona State University)
[223] Edge Length and Flake Production Strategies in the Middle Paleolithic of Romanian Southern Carpathians
In order to better understand the Middle Paleolithic behavior, it is necessary to study lithic technology beyond the inferences of typological classification. Recent advances in theoretical and methodological approaches to lithic studies have led to new perspectives on past human behavioral systems, and have shown that the 20th century industrial paradigm, still widely used in Paleolithic archaeology, is not well suited to address research questions on Paleolithic behavioral systems. One of these advances is the use of the Conservation Index, or of the edge length to mass index. This paper documents the technological
responses to lithic resource constraints, through the use of a raw material efficiency index expressed as the ratio of edge length to mass, to emphasize the efficiency with which a knapping strategy converted a mass of stone into flake edge. The data set is represented by several assemblages from significant Paleolithic sites from the region of the Romanian Southern Carpathians, e.g., Nandru-Peștera Curăță, Ohaba Ponor-Bordu Mare, and Baia de Fier-Peștera Muierii.

[124] *Very Local Vegetation Histories: Analyzing Pollen Signatures from a Wet Forest Hollow in the Ural Mountain Foothills*  
Palynologists, for the most part, sample large lakes and bogs to produce pollen diagrams that show shifts in the regional vegetation over long periods of time. Archaeologists, however, usually want to know about subtle shifts in the local vegetation that indicate intentional human use of plants. Such shifts can be discerned by examining sediment cores from smaller basins, like a wet forest hollow, that record the pollen deposited from arboreal plants in the immediate vicinity of the sampling site. In this paper, I will discuss the vegetation history of one of these small basins, a wet forest hollow in the Ural Mountain foothills (Samara, Russia). Focusing on this one place, seemingly distant from settlements and cities, I will explain how small changes in the vegetation over time indicate larger social-cultural and political changes in the region starting with the interesting absence of the forest in the Iron Age and ending with the active manipulation of the arboreal species in the forest in recent history.

[301] *A World-Systems Perspective of Early Bronze Age Fortifications in the Levant*  
This study investigates Early Bronze Age fortification walls in the Levant. The lands of Canaan and Judah in the Southern Levant were situated between larger and more populated nations. The application of a world-systems analysis framework to sites with fortification walls in this region permits unique insight into the political systems at work regarding early state formation. This report focuses on evidence retrieved from the site of Tell es-Safi over the past two field seasons (2012 and 2013). The fortifications there are compared to those at other sites in the Southern Levant. A comparison of various sites from different cultural contexts reveals diverse fortification construction strategies tailored to the specific needs of these communities. These differences may be attributed to the diverse locations, available resources, political structure, and/or cultural beliefs at these sites. World-systems analysis may help to explain the variation in construction strategies as well as provide a broader understanding of Early Bronze fortifications in the Levant.

**Porter, Benjamin (University of California, Berkeley)**  
[296] *Archaeology Should Be Undisciplined: Exploring a Four-Fields Approach in the Context of Area Studies Archaeology*  
A good test of an intellectual framework like anthropology’s four-fields approach is its durability during transfer to neighboring fields. Evaluating this transferability is particularly relevant for area studies archaeologists working in Classics, East Asian, Latin American, Middle Eastern, and South Asian Studies. Area studies archaeologists share all archaeologists’ concern for the documentation and analysis of past societies. Yet, most area studies archaeologists do not share anthropological archaeologists’ commitment to the investigation of culture as a universal phenomenon of human practice, a commitment that often provides the implicit glue between the four-fields. Area studies archaeologists
instead concentrate on history, religion, and other aspects of humanism. And yet, many themes that concern each of the four-fields circulate in area studies pedagogy and practice: an interest in the creation of materials and how they come to be endowed with meanings; emphasis on the role of language, discourse, and the production of texts; a concern for how human collectives form and dissolve; and an interest in the representation and manipulation of human bodies in art and mortuary practices. This paper explores the implications of this “undisciplining” of the four-fields approach in the practice of area studies archaeology.

Ports, Kyle (Texas Tech University)

[137] **Entering Xibalba: A Report on Subterranean Feature Investigations at the Dos Hombres to Gran Cacao Archaeological Project (DH2GC) in Northwest Belize**

Caves and subterranean features are an integral aspect of ancient Maya sacred space. For many years archaeologists have studied large intricate cave systems that can be associated with elite ceremonial centers. However, by presenting the results of the 2012-2013 excavations of subterranean features located at the site of N950 within the Dos Hombres to Gran Cacao Archaeological Project (DH2GC), this poster will focus on smaller cave features within the socioeconomic context of the Maya hinterlands. The intent of this poster is to provide interpretations using artifact analysis and spatial characteristics to understand how the Maya utilized the features located at N950. In addition this poster will present an outline of future investigations of subterranean features within the DH2GC project, new data may provide a better formulation of the roles that caves played in ancient Maya hinterland settlements.

[286] **Digging in the Dark: The Influence of Spatial Sampling in Zooarchaeological Analysis**

The choice of specific sampling strategies for zooarchaeological analysis has important implications for determining the kinds of information collected from a particular site. The location of units or spatial sampling of a site can be a primary factor in the recovery and interpretation of faunal materials. While variation in the kind, size, and formation of deposits has often led to a reliance on judgmental sampling, researchers should more strongly consider how their selections may impact results. To highlight the importance of choice, hypothetical models of basic archaeological site formations were used to test various spatial sampling strategies. Understanding the formation of faunal deposits, in particular their intermittent nature, can better inform researchers on spatial sampling techniques and what size, frequency, and location of units are required to achieve statistically significant results. This paper targets small island residential models to avoid the complexity of larger residential areas, while providing fundamental trends and insights. Establishing an adequate sample size based on the research questions and specific locations will provide more reliable information, enabling archaeologists to better compare sites and assemblages within a given area.

[23] **Technological and Economic Organization in Central Alaska: New Data from Mead and Upward Sun River**

I report on recent intrasite and intersite research in central Alaska geared towards exploring late Pleistocene to middle Holocene organization of technology and economy. This work encompasses excavations at the Mead site and Upward Sun River, where multiple feature-related activity areas in several components add to our understanding of site structural and organizational variability. Excavation and survey data from adjacent uplands suggest structured variation in land use strategies, providing a more comprehensive dataset to evaluate regional hunter-gatherer adaptive strategies. Results indicate climate change at the end of the last glacial did not alter technological strategies, though there is evidence of widening diet breadth during the Younger Dryas chronozone followed by narrowing diet breadth during the early Holocene.

Potter, James (SWCA), Mark Varien (Crow Canyon Archaeological Center) and Tito Naranjo

[194] **Performing Abundance in the Northern American Southwest**
The northern American Southwest has typically been viewed as a landscape of scarcity due to limited precipitation and relatively short growing seasons. Despite this view, Pueblo people have thrived in the region and the concept of abundance, while not typically associated with Pueblo groups, can provide insights into the dynamics that characterize their society. In this paper we use the concept of abundance to examine two important aspects of Pueblo life. The first is feasting associated with ceremonialism that was important to community social organization. In contrast to other parts of the world, communal feasting in the northern Southwest involves common, everyday “abundant” resources, such as ceramic bowls, maize, and rabbits, rather than rare, valuable, or feasting-specific resources. In this way feasting may be thought of as a communal performance of household abundance. The second is the increasing elaboration of artifact assemblages through time that were associated with both feasting and daily domestic life, particularly decorated serving bowls. By comparing the assemblages from three villages dating to different time periods, similarities and differences in these assemblages show how household abundance was translated conceptually to communal abundance through performance of the feast and through elaboration of common household items.

[317] Microrefuse Analysis from Superimposed Structures at Big Village - Range Creek, Utah

Range Creek Canyon is located in the West Tavaputs Plateau area of East Central Utah. Students and staff of the Range Creek Field Station have recorded nearly 450 prehistoric Fremont sites in the canyon, including residential, storage, and rock art sites. Of these, three large village sites have been excavated. Big Village (42Em2861) is a Fremont site with a relatively long record of occupation. Excavation at Big Village over the last three years has produced radiocarbon dates ranging from A.D. 889 to A.D. 1123. Current excavations have revealed three, possibly four, superimposed occupation levels with associated structures and hearths. Bulk fill from three hearths and floors were collected and processed through screening for microrefuse analysis. Results of microrefuse analyses have been shown to be indicative of the range of activities that occur within a structure or on a living surface. The results of the analysis of each hearth and associated floor are compared and dated to show changes through time.

[252] Middle Preclassic Development of the Main Plaza at the Ancient Maya Site of Pacbitun, Belize

Over the past 75 years, archaeologists have realized the benefits of investigating early Maya communities beneath plaza surfaces. Sites like Barton Ramie, Cahal Pech, Caracol, Ceibal, Colha, Cuello, Tikal, and Uaxactun have produced a wealth of information on Preclassic buildings, burials, and caches. In the Belize Valley, there has been a concerted effort since the late 1980s to recover as much information as possible about the Preclassic Maya by targeting plazas. This approach has been very effective at Pacbitun where we have uncovered new information on the earliest community located within the main plaza at the site. This paper reports on recent investigations in Plaza A and provides new information on E-Groups and/or Triadic Eastern Plaza Complexes that may be compared with other sites in the region to identify general patterns in Preclassic Maya development.
Domestic Complexity at 1500 B.C.: Exploring the Roots of Andean Domestic Practices within Two Casma Valley Residential Components

The Casma Valley on the North Coast of Peru was home to the Sechin Alto Polity, one of the grandest Initial Period (2100-1000 B.C.) developments. Two sites within this polity, Pampa de las Llamas-Moxeke and Huerequeque, contain well-preserved domestic zones that have been extensively excavated by the authors. Resultant data provide insights into how the resident populations participated in and responded to life within a highly centralized political and economic organization. Examples include clear evidence of social inequality in the residential sector, artifacts that document specialized production through cottage industry, and intrasite hierarchy with ramifications at the household level. Many such key Initial Period domestic practices persisted and are known from major north coast polities such as the Moche and Chimu, thereby contributing significantly to the roots of a greater Andean tradition.

Searching for Truth in Local Legends: Investigations at the Chapel of Ecuador's Oldest Hacienda

Archaeological investigations conducted in 2011 and 2012 were undertaken to explore the chapel of Ecuador's oldest hacienda. Hacienda Guachala was founded in 1580 with the inauguration of the chapel which, according to local legend, was built on top of an Inka temple. Historic records indicate that when the Spanish arrived, the site was burning having been set alight by the fleeing Inka. Pieces of the disassembled Inka baths which once occupied the site are still visible in the colonial construction and a series of collcas line the hill above confirming that the site was indeed Inka. In 1736, members of the French Geodesic Mission stayed at the hacienda. When one of the members of the expedition contracted malaria and passed away he was reported to have been buried inside the floor of the chapel. In 2008 GPR was conducted inside the chapel and revealed several anomalies. The goal of the 2011 and 2012 archaeological investigations was twofold: 1) Determine the architecture of the chapel itself to confirm whether the legends of the Inka temple are true 2) Review the anomalies picked up by the GPR in 2008 to see if the grave of the French Geodesic member could be identified.

Cultural Transmission and Diversity in Time-Averaged Assemblages

Archaeologists have adopted methods from population genetics to study modes of cultural transmission in time-transgressive datasets, i.e., assemblages. However, it remains unclear to what extent methods originally developed to assess neutrality in genes sampled from a population at a single point in time are applicable to cultural variants sampled from assemblages of artifacts that accumulated through time. Here, I apply a suite of previously published methods to assemblages simulated under unbiased cultural transmission. Even under the controlled conditions afforded by computer simulation, all but one method (the variants frequency approach) fail to correctly identify unbiased cultural transmission in samples collected from moderately to severely time-averaged assemblages. While it is encouraging that the method that is best at identifying unbiased cultural transmission in simulated time-averaged data is robust to relative sample size, additional work is needed to determine whether even the variants frequency approach is powerful enough to dependably identify “weakly” biased forms of cultural transmission in empirical assemblages.

Theorizing the Historical Development and Peak Structure of Dense Aggregate “Villages” in the Middle Fraser Canyon, British Columbia

The large “villages” of the Middle Fraser Canyon of interior British Columbia have puzzled archaeologists for several decades. With exceptionally large houses clustering in numbers of 80 or more, it is possible that some of these communities may have exceeded 1000 persons during the late portion of the “Classic Lillooet” period. Households may have been internally ranked with family space arranged around the internal peripheries of floors. Houses within villages were organized in densely packed geometric
arrangements that include lines, arcs, and circles, in some cases with distinct plaza areas. The arrangement of villages within the Mid-Fraser landscape was similarly patterned with a triad of settlement sizes with evidence for routine interaction marked by exchange of goods. This fractal pattern of settlement organization along with a range of other evidence (e.g. public feasting and other rituals) implicates the likelihood of a complex history, particularly in the period of 1000-2000 years ago. We draw from a range of theoretical models (innovation, emergence, and cultural macroevolution theory) to offer some initial statements on the nature of that history. To accomplish this, we introduce concepts of platforms, emergence, extrapolation, and exaptation as essential to this modeling process.

[76] Cooking for the Camp: An Archaeological Field School Cookbook

There is a lot more learning that goes on at an archaeological field school than just survey field methods and excavation techniques. Many students come to field school with different levels of skills, for some it may not be their first dig experience, for others it is their first real camping experience. One aspect to an archaeological field school that may take students out of their comfort level is learning how to cook for large groups; large, hungry groups of people. And each field school is different: different eating habits, different dietary restrictions and preferences. Over the course of a 6-week field school, we followed the development of students' abilities within the kitchen. Using the Mac app iBooks Author, we created a digital, shareable cookbook filled with recipes provided and cooked by the students. No matter their skill level or previous cooking experience, students are, at first, a bit overwhelmed at the prospect of cooking for a large group. But as the weeks passed and students became more comfortable in dealing with the large quantities of food, meals became more complex with additional side dishes and more adventurous starters.

[199] Painted Pebbles in the Lower Pecos Canyonlands

Small painted stones from dry rockshelters throughout the Lower Pecos Canyonlands traditionally are interpreted as ritual objects. Attributed to women's roles in increase rituals involving fertility and water abundance, specific motifs are identified as insects like butterflies and other creatures and natural phenomena relating to life cycles. Post-painting breakage of painted pebbles may be intentional and once used for their intended purposes, they no longer were sacred and were returned to secular use as mundane tools. Many pebbles, whether whole or broken, display pitting and scratching use-wear suggestive of knapping tools. To investigate these ideas and expand our understanding of the artifacts, Drs. Jean Clottes, Carolyn Boyd and I developed a method grounded in data collection. Using sophisticated imaging equipment, we analyze pebbles individually, re-creating painting sequences to examine how designs were created and to identify possible relationships between design and use-wear. We also collected extensive attribute data from pebbles to objectively identify patterns in their complex imagery. Data generated from our sample of nearly 700 specimens will allow us to analyze these patterns and provide hypotheses regarding the possible meaning, function, and significance of painted pebbles to the Archaic and Late Prehistoric peoples of the Lower Pecos Canyonlands.

[239] Contributions of the Washington Office to the Archaeology of the Northeast and Mid-Atlantic Regions

Although the River Basin Survey (RBS) program is best known from the large-scale projects performed in the western United States, archaeologists out of the Washington RBS office implemented a considerable volume of archaeological investigations in the Mid-Atlantic and Northeast starting in the late 1940s and continuing into the 1960s. These surveys comprise some of the earliest professional archaeology performed in many river systems. The benefits of the RBS to the discipline are considerable, including the discovery of important sites central to the understanding of regional culture history within the Eastern Woodlands. Early in their careers, important archaeologists such as Ralph Solecki and William Mayer-
Oakes contributed to the RBS in the Northeast and Mid-Atlantic regions.

Animal Husbandry and Secondary Products at Chalcolithic Marj Rabba (Lower Galilee)

The site of Marj Rabba, located in the Lower Galilee region of Israel, contains fourth and fifth millennium occupations. Excavations began in 2009 with the aim of understanding the evolution of complex society in the Chalcolithic period in northern Israel, a previously understudied region. Of particular interest is how the production and exploitation of secondary pastoral products figured into the local economy. In this paper, I present faunal data collected from five seasons of excavation. The results show that while textile production was important, herders did not depart from generalized production strategies. Pig production, part of an unspecialized meat economy, was particularly prominent. This likely reflects optimal environmental conditions for raising pigs in the Chalcolithic. On the other hand, pathologies to the appendicular skeleton of cattle are evidence for animal traction. This may relate to intensified production of cereal agriculture.

Social Dynamics and Economic Interactions of an Early Initial Period Maritime Community: The Gramalote Case

Recent excavations at the early Initial Period (1550-1250 B.C.) site of Gramalote, located in the Moche Valley, north coast of Peru are confirming that the households of this fishing community shared a marine-oriented economy based on shark and sea-lion meat, complemented by fish, seabirds and abundant mollusks. There is evidence that Gramalote inhabitants were practicing wetland-type horticulture to grow reeds, gourds and squash in large quantity. Some households were engaged in non-subsistence activities such as the manufacture of shell beads, basketry, mats and the production of red pigment on a large scale. These data offer a new perspective in our understanding of the early stages of Andean prehistory, based on the study of social dynamics from a bottom-up perspective. In a broader sense, this research aims to provide an alternative model to study fishing settlements, integrating subsistence pattern studies, technological aspects and the household approach.

Inscribing Identity: A Case Study of Symbolic Communication from the Iron Age Castro Culture of North-Western Iberia

How did the symbols saturating the material culture of the Castro people serve a social and political, not merely decorative, role during the Late Bronze and Iron Ages of north-western Iberia? My research explores the interconnected aspects of identity, symbols and material culture within the Castro Culture of Late Bronze and Iron Age Portugal. Using materials from five sites within the Castro region of northern Portugal, I examine the context, frequency, and association of various symbolic motifs as they appear on ceramics, domestic and public architecture, and objects of personal adornment. Comparing this data with that from excavations conducted at the Cividade de Bagunte site, I attempt to trace the ways in which the Castro people may have employed various symbolic motifs to communicate elements of personal and group identity by inscribing particular symbols in different social contexts. These symbols may have functioned to convey aspects of identity both within Castro communities and to the larger Atlantic and Mediterranean social spheres in which they participated. This paper will present the theoretical underpinnings of the project as well as preliminary research results.

The Last Neanderthals: An Examination of Climatic Influence on the Extinction of the Neanderthals
While many areas of paleoanthropology are debated, perhaps none is as contentious as that of the Neanderthals. Among the most hotly debated topics concerning Neanderthals is the question of their extinction. Why? How? When? There are a number of prevalent theories, though all experience the same problems of providing adequate proof despite the problems plaguing all prehistoric archaeology: the problem of dating, the problem of preservation and the problem of proving a reconstruction of the past. This paper aims to examine the influence of the climate upon the extinction of the Neanderthals, including why this glacial era was different from the other, as well as the importance of the coast for the late survival of the species.

Pilgrimages to Pachacamac and Titicaca in Inca Times

Long-distance and populous pilgrimages in Inca times to important shrines like Pachacamac and Titicaca were not only religious acts but played a significant role in the integration of conquered peoples into the Inca Empire and the legitimation of the power of the Incas. We propose to explore how the approach to the sanctuary, the landscape, the architecture and the shrine itself, as well as the ceremonies and sacrifices along the way, contributed to the religious experience of the pilgrims, and in what ways the pilgrims acknowledged and submitted to the power of the Inca.

Evaluating Airborne LiDAR for Detecting Settlements and Modified Landscapes in Disturbed Environments at Uxbenka, Belize

LiDAR has the potential to enhance existing regional studies of settlement distributions and landscape modifications, as well as to increase the resolution of related hydrological modeling, view shed analysis, and least cost paths. We present data from 134 square kilometers of LiDAR, which is centered on the Classic Period Maya center Uxbenká, and discuss its potential for detecting archaeological settlements and landscape modifications in areas of vegetation heavily disturbed by shifting agriculture. Vegetation density, type, and height impacts LiDAR ground reflection, evidenced in density of ground returns in the point cloud and can reduce visibility of smaller structures, terraces, and other anthropogenic features under certain regimes. Ground-truthing and comparison with pedestrian survey results allow us to estimate these limitations for varying stages of forest recovery. Profile models of ground and high-resolution (< 1m) topographic maps created from the LiDAR DEM aid in predicting the locations of otherwise invisible household groups and structures spread across the landscape.

Lost and Found: Using GIS to Identify Viable Underwater Projects

Over three decades of work has shown the viability of researching, surveying, and excavating terrestrial archaeology in an underwater context. Many of these investigations have been done in naturally submerged environments. However, over the last six decades numerous sites were anthropogenically inundated as a result of reservoir construction. Many of these sites were written off after being recorded in a flurry of investigation prior to their submersion. With the proven viability of underwater research, it is clear many such sites are still accessible for additional investigation. Unfortunately, data concerning their location, condition, age, and depth is not easily accessible. As such, they are often bypassed by governmental agencies, CRM firms, and most academic researchers. This paper presents a model for developing a GIS database that provides easy access to information concerning artificially inundated sites. The model is applied across the Great Basin and the resulting database is presented. As is shown, it provides visual, textual, and digital information on the applicable sites. This information allows potential researchers to quickly identify crucial details about site archaeology and location in order to determine the possibility and importance of conducting additional investigations at sites previously thought lost to the march of progress.

Pugh, Timothy (Queens College and The Graduate Center) [147]  The 2013 Season at Nixtun-Ch’ich’, Petén, Guatemala

A social group called the Itza occupied the Petén lakes regions of Petén, Guatemala from initial contact in 1525 until after their conquest in 1697. The 2013 field season at Nixtun-Ch’ich’ in Petén, Guatemala investigated a faction of the Itza called the Chakan Itza. The project excavated a Late Postclassic period ceremonial complex and associated domestic groups in Sector QQ and conducted a new detailed survey of part of the site. Horizontal excavations uncovered a ceremonial complex with two colonnaded halls constructed side by side. The halls were decorated with sculpted snake, parrot, and turtle imagery and included effigy and composite censers. The masonry of the halls differs from that found in other colonnaded halls in Petén. The forms of the residences in the domestic groups were difficult to document as they did not include substantial walls. Nevertheless, the residences contain a variety of artifacts and features indicative of domestic practices. The 2013 survey of the western portion of the site added details to an earlier map and remapped a large ballcourt in the northern portion of the site. Limited testing in the ballcourt revealed some details about its construction history and use.

[129]  Exploration, Mapping and Excavation of the Fluvial Shellmounds of the Guaporé Basin, Southwestern Amazonia

Shellmounds are visible fixtures of the archaeological record of the New World, being known from the California coast to Patagonia. In lowland South America, shellmounds have been noticed and studied since the Nineteenth century along the Atlantic coast of southern Brazil. Most of those shellmounds are placed near the seashore or at estuarine areas. It is little known, however, that fluvial shellmounds are also found in other settings, including the deep interior of the Amazon basin. In this work, we present the results of research in the Monte Castelo archaeological site, a fluvial shellmound in the middle Guapore basin, southwestern Rondonia state, at the border of Bolivia and Brazil. The context of Monte Castelo site is worth exploring because the excavated ceramic fragments show decorative features, such as zone-incised cross-hatching or hachure-zoning, known in some of the earliest known potteries of New World, such as Puerto Hormiga, in Colombia, Valdivia, in Ecuador, and Early Tutishcainyo, in the Peruvian Amazon. Hence, the investigation of such contexts allows for a better understanding of early contacts between the Andes and the Amazon in the pre-colonial history of South America.

[332]  Alepotrypa Cave and Its Regional Context in the Late and Final Neolithic Aegean

Current work at the Alepotrypa Cave at Diros in the Mani, southern Greece, now allows us to place Alepotrypa into a larger regional framework of the Late Neolithic and Final Neolithic Aegean. A regional survey and the excavation of an adjacent open-air site complement the continuing excavations and scientific program within the cave. Comparison of material from three areas in the Peloponnesos, Greece, where both excavation of a cave and/or open-air site and a survey have recovered material dating to LN and FN (the Corinthia, the southern Argolid, and the Mani), reveals regional variability in settlement patterns. The northern Peloponnesos (the Corinthia) follows the pattern of central and northern Greece with the establishment of multiple long-lasting open-air settlements within a region through the LN and FN, whereas the southern Peloponnesos sees single or no open-air settlements in similar sized territories in the LN. Instead, in the LN, these southern regions seem to be focused on the use of caves such as Alepotrypa, with abundant open-air settlements appearing in addition to caves in the FN. On the local level our project aims to explain the relationship between the cave and its surroundings through the LN and FN periods.

Punke, Michele

Geoarchaeology provides a different lens through which archaeologists can understand and properly address the management of cultural resources. This is true for the early planning stages of a project, during the investigation and interpretation phase, or at the end of the project when what we’ve learned should be disseminated and incorporated into the lexicon of considerations for cultural resource planning and management in a region. By viewing recent archaeological discoveries in Oregon and Washington through a geoarchaeological lens, the larger implications of these small discoveries can be understood and integrated into cultural resource management practices on a local and regional scale.

[149] From the River to the Fields: An Integrated Study of Water Systems towards a Better Understanding of Socio-Environmental Interactions
Water management has contributed to the construction and organization of human communities since the emergence of the first agricultural societies. The evolution of water availability and allocation strategies through time and its impact on cultural shifts is a socio-environmental question necessarily raised by researchers. However, traditional approaches to answer this challenge rarely consider water systems at the interface of nature and culture. Yet irrigation systems are an image of an existent agrosystem and an adaptation to a changing hydrosystem they depend upon and impact on various spatio-temporal scales. This socio-environmental signature is recorded in the hydraulic structures temporality (construction, maintenance, abandonment), their spatial organization, and sedimentary fill. The principle and limits of an integrated multi-proxi approach applied to this research object are presented and discussed in this presentation. Hydraulic structures are studied from their intake to the fields they supply, and their systemic study allows for the formulation of dynamic models of anthroposystems, locally to regionally. The study of a prehistoric Hohokam irrigation system in the semi-arid Phoenix basin, Arizona will be presented as an example. This approach is a key tool to measure the long-term vulnerability and resilience of agricultural communities and evolve from retrospective to prospective analyses.

[240] The Next Genderation: Thoughts on Mentoring Archaeologists
In 1980, slightly more than half of the incoming class of graduate students at the University of Arizona were female. There were no female archaeologists on the faculty. Today I am a member of a faculty that includes 8 archaeologists, currently all female. I have seven graduate students; one is male. My colleagues are similarly low on male students. In this presentation I will consider whether this is a discipline-wide demographic shift, or simply an artifact of an all-female faculty. Since there is still a salary and promotion gap between male and female professionals, such a shift implies a pressing need to change some of our mentoring strategies.

[155] "Unwanted Guests": Malaria and Other Parasites in 19th Century Tucson, Arizona
The Alameda-Stone Cemetery, Tucson, Arizona, was in use between the early 1860s and 1882 before
being closed. During that period, it served as the only municipal cemetery for Tucson, a city which acted as a hub of interaction between national influences from Mexico and the United States. The community was multiethnic, consisting of Hispanics, Native Americans (Tohono O’odham, Akimel O’odham, Yaqui, and Apaches), Anglo-Americans, African-Americans and recent migrants from Europe, Canada, South America, and Asia. Not surprisingly, a variety of parasites affected the people of Tucson, as well as the associated military post, Fort Lowell, in the 19th century. Drawing on historical, archaeological, osteological, archaeoparasitological, and environmental information, this paper investigates how the infection of people by several species of parasites, was impacted by changes that took place in both the physical and cultural landscape.

Qin, Zhen (Washington University in St. Louis)  
[51] An Exploration of the Process of Agricultural Intensification at Sanyangzhuang Site, Henan Province, China: A Geoarchaeological Approach

This paper focuses on the process of agricultural intensification, especially the evolution of agricultural technologies from the Early Bronze Age to the end of Western Han dynasty (roughly from 4000 B.P. to 2000 B.P.). During this period, three advances in agricultural technology were probably invented and applied: (1) The plow was intensively used by farmers to make ridges and furrows, and to maintain the porosity and permeability of the cultivated soil; (2) various kinds of manures, such as ashes and human/animal dungs, were adopted to keep the soil fertile; (3) irrigation systems were constructed to keep water accessible in the semi-arid climate condition. However, these “advances” are nothing more than hypotheses or possibilities because they have not tested by archaeological findings. In the research, the author will integrate existing findings and samples from Sanyangzhuang site and conduct geoarchaeology-based research by analyzing soil samples to see if the advances of agricultural technologies in historical documents are true or false.

QUESADA, OCTAVIO (Universidad Nacional Autónoma de México)  

In this paper, after comprehensive study of a wide sample of Olmec plastic monuments (1400-100 B.C.) the distribution of naturalistic and abstract signs of what can be called an Olmec visual language is described. In 890 Olmec pieces analyzed, four main natures were found: human (80%); serpentine (8.3%), avian (6.6%) and feline (3.1%). Among the pieces studied were found those whose nature was single and those whose nature was combined. In both cases one nature is the "noun", while subsequent natures work as "adjectives". Combinatory analyses of the four single natures and twelve possible combinations between two, show highly asymmetric data. There is a remarkable prevalence of serpentized humans, followed not closely by humans and snakes alone; other groups that are present include humans stylized with avian or feline traits; snakes bearing human attributes and serpentized birds and felines; five of the twelve possible combinations are completely absent. Furthermore, the iconic set of two opposing snakes and four abstract signs which stand for serpentine traits, are recognizable. The conclusion is that both types of signs -figurative and abstract- are the elements of a visual communication system, each with a specific function in the concerted task of creating sense.

Quick, Russell (Cultural Resource Analysts, Inc.)  
[196] No Toe-Bone Left Behind: Multi-Method Geophysics for Historic Cemetery Delineation

In the last decade, the delineation of unmarked historic cemeteries has become increasingly important as development encroaches on defunct churchyards and family cemeteries. Geophysical methods have increasingly been employed to meet the need for a fast, accurate, and inexpensive way of delineating these resources in a non-invasive manner. A recent poorly conceived study at Arlington National Cemetery, however, concluded that geophysical methods are ineffective for locating graves. This paper presents the results of surveys conducted at several historic cemeteries across the Midwest. These surveys indicate that, in a sense, the critique of geophysical methods is partially correct: the use of individual methods is not always effective. Here it is argued that the use of multiple geophysical methods,
including ground penetrating radar and magnetometry, can increase the confidence in geophysical
cemetery delineation to a level that is acceptable for cemetery management.

Quinlan, Angus (Nevada Rock Art Foundation)
Focusing on the western Great Basin, this paper explores spatial variability in rock art styles, themes, and
archaeological and landscape contexts as a first step in reconstructing how prehistoric populations may
have categorized their environments as social landscapes. Rock art locales may be understood as
assemblages of visual symbolism, produced by repeated social actions that inscribe social memory in
time-space. These enduring symbolic marks in the landscape potentially establish places of cultural
meanings that social agents draw upon to create precedents for the veracity and authority of their social
practices and roles. Rock art in the western Great Basin is only found at certain places in the landscape,
both settled and remote, raising the question of what aspects of social life were performed against a
backdrop of cultural symbolism and why these locales and the activities performed there were selected
for symbolic treatment? The roles of western Great Basin rock art and social landscapes in social
reproduction are explored through a regional sample of 130 rock art sites that range from the Middle
Archaic through the Late Archaic.

Quinn, Colin (University of Michigan)
Transylvanian Case Study
Due to a paucity of anthropologically-oriented archaeological projects, theory, and models to
systematically evaluate resource procurement, the long-term dynamics of communities in procurement
zones, areas where resources are extracted locally and exchanged widely, remain poorly understood.
Using settlement and mortuary data from the metal and salt-rich region of southwest Transylvania during
the Bronze Age, this paper explores and problematizes the dynamics of political economic models for
change in community organization in procurement zones. By looking at multiple resources, across
multiple social dimensions, and at multiple scales, it is possible to begin to characterize shifts in
community organization in resource-rich areas.

[336]  Microscopia electrónica de barrido para la identificación de textiles arqueológicos: el caso de El
Rosario, Querétaro
La identificación de textiles arqueológicos requiere diferentes técnicas, entre ellas el uso de microscopía
electrónica de barrido (MEB), que permite usar fragmentos pequeños de muestras con diferente grado
de deterioro, como materiales carbonizados. Los fragmentos textiles analizados se encontraron
carbonizados y cubiertos por sedimento sobre el segundo piso (650 d.C) del Edificio Principal del sitio
arqueológico El Rosario en Querétaro, México. Para determinar el material vegetal de elaboración, la
muestra se comparó con siete tipos de fibras vegetales locales tanto de monocotiledóneas como de
dicotiledóneas, entre ellas algodón (Gossypium hirsutum) y maguey (Agave), utilizadas ampliamente en
Mesoamérica para textiles. Las muestras fueron cubiertas con oro y observadas al MEB. También se diafanizaron y tiñeron con safranina para observarlas al microscopio de luz. La microscopía de luz permitió reconocer que el textil es una mezcla de fibras de dico y monocotiledóneas. Con el MEB se observan detalles para reconocer las fibras a nivel de especie, como el algodón que se caracterizan por ser filamentos aplastados y retorcidos con lumen amplio. También permitió reconocer que la fibra de monocotiledónea no era maguey.

Archaeological Investigations at the Barrancas Site, 8ES1354: American Period Occupation and Use during the Nineteenth Century.

The Barrancas Site (8ES1354), a large multi component archaeological site located at Naval Air Station, Pensacola, has produced a wide variety of cultural material and intact deposits related to its extensive occupation and reflective of its strategic importance on Florida’s Pensacola Bay. Past investigations of the site have focused primarily on the substantial first Spanish Period occupation at the Presidio Santa Maria de Galve and associated fortification San Carlos de Austria. However, a recent cultural resources compliance study carried out on other portions of the site have revealed deposits associated with American nineteenth century cultural components, including an Antebellum Creole home site, a Civil War Union encampment, and a post-Civil War Army installation. This paper provides an overview of the site’s later historical occupation and related archaeological remains and seeks to exemplify the Navy’s commitment to preserving this and other important historic properties while maintaining its mission.

Interpreting the Cultural Landscape at Toyon Bay (CA-SCAI-564) on Catalina Island.

Previous research on Santa Catalina Island off the coast of Los Angeles has provided valuable insight about the indigenous islanders through the lens of cultural ecology. These studies have contributed to our understanding of complex maritime hunter-gather-fisher practices that sustained Native people for over 8000 years of occupation. While this body of work speaks volumes to the prehistory of Catalina, it is here argued that Landscape theory can lend an alternative perspective that compliments previous research and builds on our understanding of social activity and the relationships of islanders. Utilizing the prehistoric village located at Toyon Bay (CA-SCAI-564) as a case study, this paper aims to present how the interpretation of satellite sites in the adjacent canyon can be analyzed through landscape theory, specifically by taskscapes as defined by Ingold. Through this powerful perspective, one can hope to view the symbolic ordering of space and place as perceived by a given group of occupants. In this sense, the landscape provides much more information to archaeologists than simply dots, boundaries, and resources. The canyon and village tell a story of generations of use tied to social relations and community.

Late-Glacial Settlement of the High Peruvian Andes

The Pucuncho Basin, located at 4480 m elevation in the southern Peruvian Andes, contains some of the oldest known archaeological sites in the Andes Mountains and the highest ice-age sites yet discovered in the Americas. Two linked Terminal Pleistocene sites occupy landforms where Alca obsidian crops out and are proximal to productive wetland habitats home to herds of Andean herbivores. The Pucuncho open-air site has fluted Fishtail projectile points diagnostic to ~12.8-11.7 ka. Seven kilometers east, Cuncaicha rockshelter contains robust occupation evidence spanning the past ~12.4 ka. Our high-resolution chronology at Cuncaicha shelter includes 35 AMS ages on ultrapurified bone collagen obtained at two laboratories, with 23 AMS ages constraining the Terminal Pleistocene component. The Cuncaicha sequence and a high-resolution glacial-geologic record developed at Nevado Coropuna just south of the basin demonstrate that despite colder temperatures, more extensive glaciers, and low-oxygen conditions, successful human colonization of the high-altitude Andes began at the end of the last ice age. Raw material and tool assemblages at Pucuncho Basin sites and the Terminal Pleistocene fishing site
Quebrada Jaguay 150 km south on the Pacific Coast suggest linkages between early sites with very different adaptations situated in diverse ecological zones.

Mesolithic Settlement in the Iron Gates Region: Integrating Current Archaeological and Geoarchaeological Evidence

This paper presents results from a recent survey of the Mesolithic sites in the flatlands and mountainous hinterlands of the Danube Iron Gates region. Previously explored and currently submerged sites located along the Danube Gorges’ riverbanks represent only a fraction of the regional early Holocene hunter-gatherers’ settlement network. Based on previous studies of stratified archaeological sites, there appear to be gaps in the record of human occupation during the early and middle Holocene in the region, which has sparked questions about the cause of such chronological discontinuities. Our study included a geoarchaeological assessment of the Holocene and terminal Pleistocene alluvial stratigraphy at a newly recorded site on the Danube River. Also, stable carbon isotope values were determined on soil organic matter from buried alluvial paleosols. Results of the investigation allow us to address the temporal and spatial patterns of recorded archaeological sites and consider geomorphic processes that have shaped that record. Our findings also provide a more reliable framework for understanding Mesolithic hunter-gatherer land-use in the Iron Gates region.

Rafferty, Sean  [172] see Nadeau, Jaclyn

Rafferty, Janet (Mississippi State University)  [216]  
Site Occupation: Repeated or Continuous Use

Even in sedentary settlement patterns, occupations can be short- or long-term and sites may be reoccupied. Short-term sedentary settlement has been documented for the Woodland through Protohistoric periods in the upland Tombigbee River valley of north-central Mississippi. It is important to examine variability within this sequence to detect and explain changes that occurred. The Middle Woodland Cork site (22Ok746) had ca. 200 1x1 m excavation units placed along an east-west ridge. Ceramic seriation shows that the west end was used first, followed in sequence by areas increasingly farther east. The site is fairly small, 20x150 m. Whether the artifacts represent a continuous occupation or reoccupation and whether each part of the site was used the same way are two issues of interest. To confirm the chronological order, a detailed stylistic analysis of hafted bifaces was done. The main variation found is in intensity of occupation, as measured by quantity and kind of artifacts recovered per cubic meter. Exotics (quartz crystal flakes, galena, and copper), while rare, have a broad distribution. The site appears to represent one occupation rather than reuse. In sedentary settlement patterns in the region, there is repeated use of landscapes, but not usually of particular small locations.

Ragsdale, Corey (University of New Mexico) and Heather JH Edgar (University of New Mexico)  [247]  
Cultural Effects on Phenetic Distances among Postclassic Mexican and Southwest United States Populations

The Southwest United States (US) and Mesoamerica are often thought of as disparate regional networks separated by Northern Mexico. Chaco Canyon in the Southwest US, Tlatelolco in Central Mexico, and Casas Grandes in Northern Mexico all had large inter-regional trade centers that economically connected these networks. This study investigated how factors such as geographic distance, shared migration history, trade, and political interaction affected biological relationships and population affinities among sites in Mexico and the Southwest US during the Postclassic period (A.D. 900~1520). Distances based on cultural and ecological variables derived from archaeological and ethnohistoric data were compared with phenetic distances obtained from dental morphological traits. The results of the Mantel tests show trade (p = 0.012), shared migration history (p = 0.004), and geographic distance (p = 0.05) to be significantly correlated with phenetic distances, while political interaction (p = 0.133) was not. Partial Mantel tests show trade (p = 0.049) and shared migration history (p = 0.003) remain significant when controlling for similarities with geographic distance, but geographic distance is not significant when
similarities with trade (p = 0.681) and shared migration history (p = 0.667) are controlled. These results highlight the importance of economic relationships and shared migration history among contemporaneous populations across geographic regions in prehistoric Mexico and the Southwest US.

[16] Scale-Free Foraging in Human Hunter-Gatherers: Lévy Walks Are a Fundamental Feature of Human Mobility

When searching for food, many organisms adopt a super-diffusive, scale-free movement pattern, called a Lévy walk, considered optimal when foraging for heterogeneously located resources with little prior knowledge of distribution patterns. While memory of food locations and higher cognition may limit the benefits of random walk strategies, no studies to date have explored search patterns during human foraging. Here, for the first time, we show that human hunter-gatherers, the Hadza of Northern Tanzania, use Lévy walk searches much of the time. Lévy walks are used when searching for a wide variety of foods, suggesting even in the most cognitively complex forager on earth, random walk searches are an essential element of foraging strategy. Lévy walk foraging is likely a key element of human prehistory, given the adoption of a hunting and gathering lifestyle nearly 2 million years ago. Super-diffusive foraging may have allowed hominins to explore larger home ranges, and may have played a role in patterns of raw material transport and residential camp distributions in the archaeological record. In the end, a greater understanding of mobility patterns and search strategy may help us better interpret interactions between humans and their environments in both the present and the past.

Railey, Jim (SWCA - Albuquerque)

[7] Long-Term Trends in Far Southeastern New Mexico: Zooming In and Out

Hundreds of radiocarbon dates from the BLM’s Carlsbad Field Office region, in far southeastern New Mexico, reveal long-term trends reflecting climate change and variation in hunter-gatherer mobility, subsistence economics, and settlement organization. How mobile hunter-gatherers responded to climatic downturns, such as the onset of the Medieval Dry Period, remains a key question for this on-going research. Did groups in the Mescalero Plain concentrate at surviving water sources, did they migrate to better-watered locations (such as the Pecos River and mountain foothills to the west), or did some combination of both occur? To explore this question, I zoom into the Cedar Lake Playa Depression. This presumed oasis has hosted numerous archaeological excavations, which have produced over 70 radiocarbon dates. The cumulative frequency of dates from here is, overall, similar to that for the region as a whole. Compared to the broader region, however, dates from the Cedar Lake area show an even more precipitous frequency plunge following the onset of the Medieval Dry Period. This suggests the possibility that many people may have simply left the Mescalero Plain at this time, or perhaps the Cedar Lake Playa was not a favored oasis at this time.

[44] Scratching the Surface: Surface Sampling of the 76 Draw Site, Luna Country, New Mexico

Archaeologists in the American Southwest have long used examinations of surface artifacts to assess potential subsurface deposits, relatively date sites, assess cultural affiliation, and select locations for excavation units. However, various factors including alluvial and aeolian processes and historic and contemporary land use can impact the distribution and density of surface materials. This poster reports the results of an intensive surface sampling and mapping of the 76 Draw site in southwestern New Mexico. The purpose of this sampling was to assess how useful surface artifacts are at providing indications of subsurface deposits, provide guidance for future subsurface excavations, and assess cultural connections between the Casas Grandes, Salado, Black Mountain, and El Paso Phase Jornada in the Animas region.

**Patterns of Settlement Hierarchy in the Lurin Valley during the Late Intermediate and Late Horizon**

The purpose of this research will be to examine the patterns of settlement hierarchy present at various sites located throughout the Lurin Valley during the Late Intermediate and Late Horizon periods. My work will attempt to first establish these patterns and then also to identify potential similarities between them at sites such as Panquilma, Tijerales, and numerous other areas. Using computer-based models, I seek to analyze the spatial relationship of these sites both in relation to one another and also in relation to their location within the valley as a whole. Furthermore, I intend to examine how the positioning of these sites and, subsequently, how the relationships between them potentially influenced the intra-site characteristics present within their respective locations. In essence, my work will first discuss the ways in which physical location as well as site proximity in the valley shaped the intra-site characteristics of many of the Lurin Valley settlements. It will then examine the social dynamics present at each of these sites in relation to settlement hierarchy and compare them to surrounding areas in order to better understand the socio-political relationships between sites in the valley during this time period.

**Fish[i]stories: Seafolk of the Northern Peruvian Coast**

This paper summarizeschroniclers’ accounts and other primary source references to fisherfolk in the colonial era found in the archives of Spain and Peru. It focuses primarily on the sixteenth century, years in which coastal inhabitants suffered devastating losses from exotic, unknown diseases; confronted the arrival of foreign invaders who did not speak any of the Andean languages; witnessed the breakup of ethnic groups and the assignment of different segments to new masters with needs that were very different than those associated with Inca hegemony; resisted pressures to change gods and disavow ancestor worship; heard about and saw new cultural forms – including new definitions of morality, right and wrong; built newly mandated homes and settlements sometimes far from their previous homesteads; and protested the loss of geographical mobility so crucial to the exploitation of the multiple available resources necessary for basic subsistence. The analysis shows that fisherfolk formed an integral and important segment of the populations of all the major curacazgos (chieftainships) on the north coast, interacting actively with their farming neighbors.

**Social Organization in the Aztatlán Tradition (850-1350 A.D.): The Sayula and Chapala Basins (Jalisco), a Case Study**

Social organization during the Aztatlán Tradition is quite unknown. Research in several areas in Western Mexico has given some insights about how Aztatlán groups were politically, economically and ideologically structured. Archaeological research in the Sayula Basin, together with comparative studies in the Chapala Basin, indicates that the Aztatlán network could be organized into political units that shared different ritual activities, burial patterns, ceramic styles, specialization, exchange, etc. Each political unit had a major site, a cabecera, where the high status people lived and perhaps controlled the regional exchange and specialization within that political unit.

[316] Hydropower and Cultural Resources Management: A Case Study from California’s Sierra Nevada

The Federal Power Act (16 USC ch.12) provides the Federal Energy Regulatory Commission (FERC) the authority to license non-federal hydropower projects on navigable waterways and federal lands. Over the last decade, many utility and power agencies have been in the process of renewing their FERC licenses and as such are required to comply with federal laws and regulations, including Section 106 of the National Historic Preservation Act. HDR Engineering, Inc. has been instrumental in this process and has been tasked with the inventory, evaluation, and treatment of historic properties affected by the ongoing operations and maintenance of a number of hydropower projects. This poster explores some of the challenges for inventorying cultural resources at large hydroelectric projects through a case study of the Yuba River Development Project, located in the northern Sierra Nevada of California. Much of the landscape, particularly around the project reservoir, is extremely steep terrain with dense vegetation. This environment presented a number of difficulties in conducting intensive archaeological surveys in order to thoroughly identify cultural resources that might be affected by the project.

Randall, Lindsay (Robert S. Peabody Museum of Archaeology)

Linda Cordell was more than a supporter of the Robert S. Peabody Museum of Archaeology in Andover, Massachusetts; she was one of the museum’s most eager hands-on partners. Linda’s passion to support student learning and her enthusiastic guidance influenced several educational programs at the Museum. Pecos Pathways, one of the museum’s signature educational programs, brings together students from Phillips Academy, Jemez Pueblo, and Pecos, New Mexico to learn about ancestral and contemporary native communities. This program allows students personal interactions with tribal elders and archaeological experts. Among the professional archaeologists, Linda stood out to the students as the most relevant and accessible. Students enjoyed her expertise and supportive nature, but also her sincere desire to listen to and learn from them. Linda’s passion for teaching young adults also extended into the Phillips Academy classroom. Linda championed the integration of experts and real world experiences into the classroom to enhance student knowledge and understanding. Linda Cordell was an unparalleled mentor and educational resource for the Peabody Museum, and helped to positively shape not only students, museum educators, but the Peabody Museum as a whole.

[213] Migrating Mounds Unsettled by Climate Change: Insights from Archaic Period (ca. 7400-3500 B.P.) Communities of Florida

Movement defines hunter-gatherer lifeways. Ecological approaches have foregrounded the necessity of seasonal mobility between patches for successful resource acquisition. In contrast, a consideration of hunter-gatherer social landscapes highlights the centrality of movement to ongoing community identity construction and social memory work. Landscapes emerge from pathways and itineraries that connect places, times, and persons. In this relational view, movement between and experiences within places are naturalized as social and mythic histories such that moving between place is also movement in time. In this paper I consider how social landscapes are reconstituted when histories are unsettled by climate change. In particular, I focus on the culture history of Archaic period (ca. 7400-3500 B.P.) communities of the St. Johns River valley in Northeast Florida. A prominent component of Archaic landscapes was the creation and management of a network of shell mounds. These places had various lives as residences, ceremonial platforms for aggregations, or burial mounds. Although physically enduring, the social and ecological conditions that sustained them varied historically. Site biographies reveal that shell mounds - as socially significant places - migrated as old mounds were displaced and new ones were incorporated into the social geography of the St. Johns.

Ranhorn, Kathryn (The George Washington University), David Braun (The George Washington University) and Alison Brooks (The George Washington University)

The Levallois reduction strategy is often considered a key component of Middle and Later Pleistocene industries. It has been linked to derived degrees of planning and forethought associated with “prepared core” techniques. However, unambiguous quantitative methods for identifying Levallois reduction in the archaeological record remain problematic. The debitage products of Levallois reduction are often employed to identify Levallois technology but these flakes may be obtained through other knapping strategies. Instead, Levallois cores are likely to preserve a better understanding of the reduction strategy, especially if refitting is possible. Boëda defined diagnostic criteria of Levallois reduction, yet identifying
these criteria remains subjective. Here we develop a quantitative technique for identifying Levallois reduction guided by principles in Boëda’s definition, namely the presence of two asymmetric, hierarchical faces with opposing convexities. To test the validity of these criteria we employ photogrammetric methods to capture three-dimensional form of cores from various archaeological sites across Southwest Asia, Europe, and Africa. Core forms were captured as high-resolution 3D models. This enabled the visualization and shape quantification of portions of cores (e.g. hemispheres) that would otherwise be unattainable with conventional measurements. This research lends new perspectives on the quantitative identification of Levallois technology in the archaeological record.

Rauscher, Erika (Wagner College), Shevan Wilkin (University of West Florida) and Danielle Kurin (University of California Santa Barbara) [103] Trauma and Trepanation in Highland Peru

This paper evaluates whether increasing violence during the Andean Late Intermediate Period ([LIP], ca. A.D. 1000-1400) is associated with an increase in trepanation (ancient cranial surgery). Crania (n = 113) excavated from cave burials at two LIP settlements, called Sonhuayo and Ranracancha, located in the Chanka heartland of Andahuaylas, Peru, were evaluated for evidence of trauma and concomitant trepanation. The total number of wounds and total number of trepanations were calculated for these two contemporaneous communities. Results demonstrate that over 60% of observed individuals possessed at least one cranial injury, with several displaying numerous wounds. Trepanations were present on several crania with trauma. Social factors also structured trepanations as all affected individuals in this sample had modified crania. Evidence for multiple surgical techniques including scraping and circular grooving show definite signs of healing, and signal attempts to ensure the survival of wounded patients.

Rautman, Alison (Michigan State University) [246] Theorizing Archaeological Cultural Landscapes: Local Knowledge and Archaeological Practice

Archaeological study of cultural landscapes considers both natural and constructed places that were inhabited and also imagined by particular human communities in the past. Archaeologists of the deep past such as the European Mesolithic thus commonly engage with theory from human ecology, phenomenology, material culture studies, and other fields. Notably absent (by definition) is the significant input provided by collaboration or connection with indigenous perspectives, or by partnership with people who trace a direct historical, biological, and/or cultural connection to the past inhabitants of a region. Thus, archaeologists who can engage with a well-defined local descendent community might seem to have a much easier time in understanding the varied interactions between humans and their natural, social, and cultural setting. However, a brief review of the literature in cultural anthropology and in the philosophy of social science reminds archaeologists of some of the more ambiguous political, ethical, and theoretical issues involved in integrating local knowledge (sometimes called indigenous knowledge) into diverse research contexts. This cautionary note highlights archaeologists’ shared problems of describing, interpreting, and understanding the past, regardless the time depth involved.

Ray, Erin (University of California, Merced), Hector Neff (California State University, Long Beach) and Holley Moyes (University of California, Merced) [277] Ritual Cave Use at Las Cuevas, Belize: Preliminary Results of Geochemical Analysis

The cave at Las Cuevas located in Belize, C.A. is unique as it features an extensively modified entrance chamber. To date 64 platforms, 7 staircases, and 2 sets of terraces have been mapped and recorded. Most of the architecture has been plastered and some of the plaster is still intact. Our research aims to
discover the function of the platforms in the cave entrance. We hypothesize these platforms were used for rituals that may have included burned offerings, dancing, and bloodletting. To test this we have used morphological and geochemical analyses. We have used high resolution mapping to examine minute differences in topography. Geochemical analyses were conducted in the field using portable XRF (pXRF). Additional samples were collected for laboratory analysis including Inductively Coupled Plasma Mass Spectrometry (ICP-MS) and Fourier Transform Infrared Spectrometry (FTIR). In this paper we will present our preliminary results and discuss possible ritual practices.

Calf Creek on the Eastern Horizon
The eastern distribution of Calf Creek appears to terminate in the western Ozarks region. Although Calf Creek artifacts are found in this region, they are not as common as other contemporaneous point types. The presence of Calf Creek in this area is viewed as an expansion of the Calf Creek manifestation into the western portion of the Eastern Woodlands during terminal Middle Archaic times. This expansion involved an adaptation toward the exploitation of forest and stream resources. The Calf Creek expression in the western Ozarks is discussed in terms of settlement distribution, chert resource procurement, technology, and subsistence.

Raymond, Tiffany (Mississippi State University) [260]  
Exploring Freshwater Mussel Shell Ring Sites in the Mississippi Delta: Preliminary Results from 22YZ605 and 22YZ513.
In recent years, research has been focused on shell ring sites along the Atlantic and Gulf Coasts. These sites have been demonstrated to represent sedentary, hunter-gatherer populations during the Archaic (Russo 2006). Relatively unknown to the archaeological community are the numerous freshwater mussel shell rings located in the Yazoo Basin of the Lower Mississippi Valley. Dozens of these sites recently have been identified using aerial photographs (Peacock et al. 2011). These freshwater shell ring sites are mainly documented in gray literature reports, where a very limited amount of information is available. This paper will present preliminary results from excavations at two freshwater shell ring sites in Yazoo County, Mississippi. These results will include a comparison of LiDAR data and aerial images of the sites, as well as the age as determined from surface collection and excavation.

Hilltop Enclosures and Changing Uses of Ritual-ceremonial Space in Woodland Northern Ohio
Debate over the builders and users of hilltop enclosures in northern Ohio has gone on for more than a century. Originally viewed as “Moundbuilder” fortifications, these important sites are now seen as multi-component habitations of local Woodland and Late Prehistoric-era societies. Questions concerning the relationships between ritual, domestic, and defensive activities at these sites remain. Recent study of the Heckelman site in north-central Ohio provides evidence for Early Woodland (cal. 600 to 100 B.C.) construction of two parallel ditches (and presumably embankments) to enclose a 0.60 ha section of riverine promontory. In addition, a ritual/ceremonial precinct demarcated by a 0.13 ha oval (ditch) enclosure was constructed within the larger enclosed space. Activities here focused on the erection and removal of large (ceremonial) poles and limited domestic-residential functions. The succeeding Middle Woodland, Hopewellian, occupation (cal. A.D. 235 to 435) significantly altered this ceremonial landscape and established a domestic presence marked by discrete household clusters, which were in part focused on the production of mica artifacts, cache blade/preforms, and possibly mound ceremonialism. This Ohio Hopewell-inspired occupation is currently undocumented at any other hilltop enclosure in the region and marks a distinct shift in the perception and use of ritual space.

Reed, Paul (Archaeology Southwest) [56] Puebloan Occupation of the Middle San Juan and the Chaco Frontier
Research completed over the last dozen years has clarified and enhanced our understanding of the area between Chaco Canyon and Mesa Verde. Ancient Pueblo people in this Middle San Juan region blended characteristics of both areas north and south but nevertheless created their own unique manifestation. Chacoan migration into and colonization of the area in the late eleventh century brought substantial change and lasting but diverse hegemony for 200 years. Despite Chacoan influence and minor presence in the greater Mesa Verde region to the north, the northern limits of the Middle San Juan (roughly the current New Mexico-Colorado state line) arguably represent the beginnings of the northern Chacoan frontier. Manifestations of Chacoan hegemony north of this line were much weaker than those south of the line. In this paper, I explore this apparent boundary and its implications for our understanding of the dynamic Chacoan and post-Chacoan periods. [18] Discussant

Reed, Lori (Aztec Ruins National Monument), Linda Wheelbarger (San Juan College) and David Witt (SUNY Buffalo) [56] Ancestral Great Houses in the Northern Borderlands: Chacoan Hegemony at Aztec North and Point Pueblo
As Chacoan hegemony expanded into the Middle San Juan region, the great house communities at Aztec North and Point Pueblo were local representations of a growing frontier. Point Pueblo and its surrounding community were established as early as the mid to late A.D. 900s and may represent one of the earliest and longest lived great houses along the San Juan River. Aztec North and its community along the terrace north of the Animas River was established during the late 1000s, but eventually was transformed by the monumental built-environment of Aztec West and East. These two great house communities developed along different trajectories representing the dynamic cultural landscape characteristic of the Middle San Juan river valleys prior to the expansion of Chacoan colonies at Salmon and Aztec West. Point Pueblo and Aztec North were engaged in regional networks and power structures, which necessarily reacted to the evolving nature of political, religious, and economic boundaries. Through an examination of site layout, architecture, and ceramics, among other material items, this paper investigates how local Middle San Juan folks negotiated the shifting centers of power as Chacoan hegemony was established.

Reeder-Myers, Leslie (Smithsonian Institution) [77] Climate Change and the Archaeological Record of North America’s Coasts
Twenty-first-century global warming poses a significant threat to the archaeological record of coastal regions, but the effects of sea level rise and changing weather patterns will not be evenly distributed. This study compares the vulnerability of cultural resources in three parts of North America—the mountainous coast of southern California, the sandy shores of the Texas Gulf coast, and the tidal reaches of the Chesapeake Bay estuary. All of these areas have already seen sites submerged under rising tides or lost to storm erosion, but variability in coastal geomorphology, rates of relative sea level rise, and the structure of prehistoric settlement systems produce different patterns of vulnerability. Spatial modeling using geographic information systems allows survey and testing to target the areas that are most threatened. Results suggest that the archaeological records of all three areas will be impacted by global warming, but that the Texas Gulf coast faces the greatest double threat from sea level rise and erosion. The rich cultural heritage of North America’s coasts is likely to be severely damaged, along with the record of how ancient people adapted to similar problems.

Reedy, Chelsea (Chelsea Aurelea Reedy) [208] Experimental Spiral Fractures Based on Butchering Analysis at the Bull Creek Site
Bull Creek is a 9,000 year old campsite in the Oklahoma panhandle affiliated with the late Paleoindian Plainview culture. Excavations uncovered bison bones with strong indication of human manipulation. Based on the argument that experimental butchering can provide evidence that the manipulation of the bison bones at the Bull Creek site was the result of human activity, an archaeological experiment was set up which focused on creating “green bone” spiral fractures seen on the Bull Creek specimens. The experiment successfully replicated the breakage patterns observed at Bull Creek suggesting that the bone modification was the result of human activities rather than trampling by animals.

[64] Ancestry in Progress: The Construction of a Descendant Community for a Cadaver Skeletal Collection

This paper reflects upon past attempts to identify a living descendant community for the W. Montague Cobb skeletal collection, a cadaver skeletal collection based in Washington, D.C. The paper moves on to highlight current strategies being employed for this purpose. In doing so, it explores the construction of descendant community as a political and research strategy that enhances the skeletal biological study of ‘communities’ of people whose remains are housed in research institutions. The paper argues that the construction of a descendant community is an integral part of understanding the shared past connectedness of the people whose remains we study, as well as understanding longitudinal connections between these persons and those living in the present. This includes a critical examination of our relationship to these collections as part of a community of researchers situating the individuals therein as both agents and subjects. As such, this discussion also presents an opportunity to explore issues of accountability that are associated with how of researchers’ work linking communities together in the past and present is perceived.

Reese, Kelsey (Washington State University)

[289] Letting the Data Define the Terms: Mapping Community Size and Expanse in Mesa Verde Proper

Producing a succinct and accurate definition for a “community” has been a challenge for scholars of Southwestern archaeology. Quantitative definitions consider temporal, geographic, demographic, and social dimensions to produce a definitive region in which individuals are expected to interact on a regular, if not daily, basis. Conversely, qualitative definitions are concerned with the presence or absence of kin members within the sphere of interaction, or the use of kinship as an organizational strategy. Regardless of the approach, the researcher is hindered by the limitations of the data set— incomplete survey data, lack of excavation to support observations made during survey, etc. The dataset available in Mesa Verde National Park provides a unique opportunity to explore the periods of aggregation and disaggregation that occurred between A.D. 600–1280. The analysis is done by calculating the least cost paths among all contemporaneous habitation sites on Mesa Verde proper and determining the likely degree of aggregation and expanse of community through time. This paper offers a means of defining “community” based on empirical data, taking into account temporal fluctuations of aggregation, and addresses the difficulties of manipulating and analyzing large data sets.

[61] The Preclassic Landscape of Yaxnohcah

The Preclassic landscapes of the lowland Maya reflected their understanding of cosmic and social order. E-groups are situated at the heart of these landscapes and are among the first constructions people create upon colonizing an area. However, in many cases, they are not the only, or even the initial, complex established within early communities. At Yaxnohcah, the Brisa complex, an early E-group, lies in the center of a vast dispersed settlement comprised of voluminous platforms. Recent excavations have revealed that the Fidelia complex was initially constructed during the early Middle Preclassic, prior to the earliest E-group platform. During the later Middle Preclassic and again during the Late Preclassic, the site was enlarged and the architecture amplified and elaborated. Ramps and sacbes lead out from several platforms. One sacbe links the Alba complex, a large triadic group, to a ballcourt and establishes a strong north-south orientation to the civic precinct. Therefore, within this paper, I consider the corpus of architectural forms at Yaxnohcah. These architectural constructs, the E-group, the triadic group, the ballcourt, and sacbes are essential elements of a founding landscape and work in concert to embody the evolving cosmological and social worldview of the lowlands Maya during the Preclassic.

[152] Transforming Metal Detectorists into Citizen Scientists

In 2012, the Archaeology Department at James Madison's Montpelier began an experimental program with Minelab Americas to encourage metal detectorists to become more involved in the scientific process
of archaeological research. Specifically, the program was designed to be a week-long experience where archaeologists and metal detectorists would work together to identify and preserve archaeological sites at the 2700-acre Montpelier property. In the process, the metal detector participants were taught the importance of site preservation through background lectures and detailed information on how the survey methods they employ during the week with their metal detectors ensure minimal disturbance of the site while identifying enough information regarding the site to ensure its preservation. Participants learned how grided metal detector surveys were conducted and the importance of proper context and curation of recovered objects. In turn, participants provided feedback on what would enhance the experience to inspire continuing learning and interaction with archaeology in the future. The success of this program led to a new public-set of programs that are held three times per year and are open to the public. Having previous participants recommend this program to their friends and community members has been integral to the success of the programs.

Regnier, Amanda (University of Oklahoma) [240]  
Ceramic Studies and Feminism in the Southeast
Throughout my career, my research has been focused on the analysis of styles of ceramic production and decoration, and how both reflect social practices across communities in the prehistoric Southeast. While my studies are focused on an aspect of material culture generally attributed to women, I have been reluctant to identify my research as explicitly centered on the activities of and relationships between women. In this paper, I explore possible reasons why, as women have gained a greater foothold in the archaeological community, I have downplayed the extent to which my own research is focused on the activities of women in the past.

[154] New Discoveries from 3D-Modeling of the Paracas site of Collanco, Peru

In our research project on the Paracas culture in southern Peru we discovered hitherto unknown settlement structures in the highland regions of the Andes. The size (up to 3 km²) and complexity (densely packed settlement clusters) of these settlements constitute a serious challenge for archaeological documentation. In cooperation with the German Archaeological Institute and the ArcTron3D company, the latest methodologies and techniques of remote sensing and 3D-modelling were employed in order to achieve a satisfactory documentation of the settlement structures. In our contribution we present the ongoing work for the documentation of the settlement of Collanco.

The 3D documentation of Collanco in 2013 took four days on site and produced a three-dimensional record of a 4.5 km² area—including archaeological terrace structures on about 2.5 km². The airborne image documentation (SFM - Structure from Motion) was carried out from a paraglider. Additionally, a high-resolution landscape model including the terrace structures was recorded using a long-range terrestrial 3D laser scanner (Riegl VZ-400). Photogrammetry and laser scanning were deployed in combination as well for a detailed record of a selected small settlement area with subcentimeter accuracy. All 3D models were brought together in the archaeological 3D information system aSPECT 3D.

Reiser, Marcy (University of Arizona) and Lawrence Todd (University of Texas, Austin)

[265] When Trees Won’t Talk: Authenticating Potential Modified Trees with an Unknown Past

Dendroarchaeology can be an exceptional scientific tool for chronicling past human land use. The scars left on culturally peeled trees, injury caused by ancient harvesting and bark removal activities, are often distinct and recognizable. They are symmetrical and ovate in shape, located well above the ground with a midsection at roughly breast height, and, with any luck, the indisputable presence of cut marks. But what to do when scarred trees display few or none of the tell-tale signs of human modification? Trees in the Caldwell Basin of northwestern Wyoming are a case in point. Ravaged by the 2011 Norton Point Fire, these trees no longer retain conclusive evidence of cultural modification—if, indeed, they ever did. The trees themselves are mere shadows of their former existence and even the scar morphology—when it can still be detected—has been irretrievably altered by the fire and any potential cut marks obliterated. With no archetypal cultural indicators, a broader set of criteria must be used to identify and authenticate potential culturally peeled trees including: fire history and ecology, estimations of scar morphology, spatial and temporal distribution of scars, and the archaeology of the area.

[250] Cultural Responses to Mid-Holocene Environmental Changes along the Pacific Coast of Peru

Sitio Siches (PV 7-19) is a preceramic site located at 40 24’ S on the Pacific coast of Peru. The occupation is divided into three cultural phases: Honda (5150-4550 14C B.P.), Siches (6000-7100 14C B.P.), and Amotape (9000-9500 14C B.P.). The vertebrate assemblage is dominated by marine vertebrates; 57% of which are warm-water individuals and 37% are typical of cool-water settings. Warm-water vertebrates increase from half of the individuals in the Amotape and Siches collections to over 80% in the Honda collection, suggesting a change in marine conditions. This is accompanied by an increase in mean trophic level and a decline in diversity. At the same time, invertebrate remains from Amotape and Siches levels are warm-water, while the Honda invertebrate assemblage is mixed warm- and cool-water species. These trends likely reflect cultural responses to mid-Holocene environmental changes.
occurring between 6000 and 5000 B.P. Due to preservation, plant remains are more poorly represented than faunal remains. The plant assemblage includes phytoliths of Cucurbita spp. from the Early Holocene Amotape assemblage identified by Dolores Piperno. Siches and Honda deposits include Lagenaria sp. The early presence of plant domesticates at Siches may reflect, in part, the site’s location above a permanent seep.

Reitze, William (University of Arizona) [166]  
*The Kinchloe Site: Agate Basin Occupation in Central New Mexico*  
The Kinchloe site is a Late Paleoindian (Agate Basin) site in the Estancia Basin, New Mexico. The Estancia Basin contained the eastern most pluvial lake in the Southwest, presenting a unique opportunity for Paleoindian foraging groups during the Pleistocene/Holocene transition. The Late Paleoindian occupation, however, postdates the final desiccation of the lake. Drawing comparisons between Kinchloe and Early Paleoindian occupation in the basin allows for the reassessment of models of Paleoindian mobility, landscape use, and site distributions as they shift during the Pleistocene/Holocene transition. This paper presents a reinterpretation of the Kinchloe site in the context of an ongoing full reassessment of the extant Paleoindian and Archaic surface collections from the Estancia Basin.

Rendu, William (CIRHUS) [16]  
*Neandertal Mobilities in Southwestern France: A Zooarchaeological Perspective.*  
Recent works on the late Middle Paleolithic from Southwestern France have identified the existence of diverse populations characterized by distinct cultural features, attesting that several Mousterian societies succeeded one another through time. These societies evolved under different paleoclimatic contexts, adopting original strategies to exploit their biotope. However, the majority of the zooarchaeological approaches focusing on the spatial distribution of the activities within the territory has considered the Neanderthal populations as a unique entity and few studies have really discuss the diversity of the mobility pattern developed by the Mousterian societies in Southwestern Europe. We propose here to tackle this issue through the study of two distinct groups from this region: the Quina Mousterian and the Mousterian of Acheulean Tradition. By taking into account several zooarchaeological criteria—faunal spectra, game selection, selective transport, hunting seasonality—we highlight the choices made by these populations, leading them to major modifications in the spatial organization of their subsistence activities. Indeed, we advance that have developed different hunting behaviors that might have for consequence the adoption of two distinct mobility patterns and therefore two different social organizations.

*Phosphate Analysis of Prehistoric Structures in Rio Blanco, Manabí, Ecuador*  
Archaeologists have identified many prehistoric structures affiliated with the Manteño culture (500 C.E. to 1532 C.E.) of coastal Ecuador, but the function of those constructions is rarely understood. A few are associated with U-shaped seats, suggesting elite or ritual use, but the majority of the buildings have not yet yielded clear evidence of their function. As part of an ongoing project to explore the function of these buildings by Florida Atlantic University, I conducted systematic soil phosphate testing in and around two archaeological structures and, for ethnoarchaeological comparison, four contemporary households. I collected the samples in a grid pattern at 2-m intervals both inside and outside the structures. I measured the concentration of soil phosphates using a modification of the Melich II method developed by Richard Terry and his colleagues. I found clear spatial patterning in phosphate concentrations in and around the archaeological structures. The concentrations were higher inside the structures, while outside they decreased with distance from the structure. Also, the patterns associated with the two archaeological structures are different, implying different functions for the constructions. Comparison with the modern households suggests one structure was a storage area for organics and the other structure was a habitation.

*Islands in the Mountains: Insularity and Socio-Political Developments of Societies in a*
Mountainous Landscape

The Zagros Mountains in western Iran consist of countless valleys in between intimidating mountain ranges. Studies of this region have focused mostly on major trade routes crossing the Zagros Mountains. Site-specific research in the Zagros Mountains usually attempts to fit each site within a supraregional framework of long distance interaction, both chronologically and culturally. As a result, current scholarship presents the communities that occupied the Zagros as peripheral to the major political and cultural developments of the ancient Near East, thereby modeling this mountainous region as a borderland passively absorbing outside influences. Drawing on robust models of intra- and inter-regional interaction developed to understand the archipelago of the Aegean world, I demonstrate that Zagros valleys can be understood as islands delimited not by a body of water but by mountain chains which put restraints on patterns of communication. I show that a model which includes concepts of insularity and a multiscalar network approach can be a productive way to describe modes of communication and the formation of complex societies in mountainous regions. This model can be applied to socio-cultural developments in mountainous regions generally, thereby offering a methodology to move beyond standard approaches that emphasize their peripheral nature.

[200] Landscapes in the Making in the Sextín valley of Durango, Mexico

In this paper we present the results of recent investigations along the Sextín river valley in Durango, Mexico. Specifically we consider how the inhabitants built and resignified the spaces they inhabited, focusing on architecture and material culture. We take into account the centuries of occupation in the valley as we reevaluate models proposed by previous studies in the region and analyze the relationships between diverse actors as reflected in objects and architecture through time.

[32] Communal Structures and Village Integration at the Harris Site

When Emil Haury excavated at the Harris site in the 1930s, he excavated three sequentially used communal structures that surround a large central plaza. During current work at Harris, we have excavated a fourth communal structure and a small portion of the plaza. In this paper we look at the role of both the communal structures and plaza in village integration. We discuss the important role that both played within the village and within this portion of the Mimbres Valley.

[206] Fragmentation of Late Prehistoric Faunal Remains in Northeastern Colorado

Site 5JA421 is located in North Park, Colorado and represents a Late Prehistoric processing camp. Our
analysis of faunal specimens recovered from this site revealed that the assemblage is highly fragmented, with 86.54% of the specimens measuring less than 5 cm at their maximum length. This intense fragmentation has generally been interpreted by archaeologists working in northeastern Colorado as evidence for grease and marrow processing. With minimal evidence for severe damage to the assemblage by other taphonomic forces, it is likely that much of the fragmentation of the site’s faunal remains can be attributed to processing by humans. Human processing could also account for the low frequency with which specimens appear to have been directly burned, as fat, grease, and various nutrients are acquired through the boiling of fragmentary faunal remains. As subsistence data from prehistoric sites across northeastern Colorado are relatively sparse, the evidence provided by the faunal remains at 5JA421 represents an important component toward creating more complete reconstructions of Late Prehistoric site use, prey choice, and processing decisions across northeastern Colorado and beyond.

[148] Re-assessing Paleoarchaic Plant Use at Bonneville Estates Rockshelter
Preliminary analyses of botanical materials from features dating older than ~10,000 years cal B.P. at Bonneville Estates Rockshelter (BER) and Danger Cave have suggested dietary use of certain plants (particularly cactus pads, and possibly some seed plants; Rhode and Louderback 2007). Now that archaeobotanical analyses of the early Holocene BER record is completed, a reassessment of those preliminary results can be made, including comparisons with possible dietary plant usage derived from other Paleoindian sites in the Great Basin and western North America.

[189] The People of the Shaft and Chamber Tombs: An Examination of the Human Skeletal Remains from the Middle Formative Period El Embocadero II Shaft and Chamber Tomb
Funerary rituals and humans remains, in their death, provide evidence of life. By examining population demographics, biological markers of status and identity, and skeletal pathologies within the funerary context, it is possible to get a better understanding of past lives. This contribution examines the Middle Formative period shaft and chamber tomb site of El Embocadero II. This cemetery includes textile wrapped burials and traditional interments with variation in grave goods, providing the opportunity to examine differences in identity, status, and health. Biological markers examined include enamel hypoplastic defects, oral health, cranial modification, and skeletal pathologies. There are 25 individuals from 14 tombs. 40% are subadults with most dying between 2-12yrs. Adult age at death is variable with some living beyond 50yrs, but most dying between 35-50yrs. There are twice as many females as males. There is little biologically distinctive in those tombs or interments with the greatest number of offerings. Those interred in the wrapped burial style show more signs of physiological stress and do not appear to be higher status. The children display the most severe pathological changes while adults primarily display degenerative joint disease. Cranial modification is seen in a variety of interments.

Rice, Prudence (Southern Illinois University)

[147] Contact- and Colonial-Period Pottery in the Western Lake Petén Itza Basin
The western basin of Lake Petén Itza was continuously occupied from the Late Postclassic through the Contact and Colonial periods. Excavations at the sites of Nixtun-Ch’ich’ and Tayasal have yielded several kinds of pottery specific to these centuries. Some demonstrate long continuities with indigenous Maya types and wares and extend into modern times. Other material, for which we borrow the term “colono- ware” from the Southeastern U.S., exhibits a mixture of Maya and introduced (presumably European) characteristics. A third category of pottery is European-manufactured or -inspired, such as rare fragments of botijas (olive jars) and tin-enameded ware (majolica; loza) from primarily Guatemalan and Mexican sources. These ceramics provide insights into the changing interactions of the Itza Mayas in
Rice, Erin (University of Illinois at Chicago)
[84] Obsidian in the Southern Levant: A Comparative Analysis Using pXRF
The importation of obsidian artifacts in the Southern Levant from Anatolian sources illustrates the importance of long-distance exchange networks during the prehistoric period. The vast distances over which this material is moving combined with its relative scarcity within archaeological assemblages in the Southern Levant allows for a unique perspective of the economic and social interactions in this region. This study provides a comparative view of the importation, distribution, and use of obsidian within and between several Pre-Pottery, Pottery, and Chalcolithic sites located in central and northern Israel. The primary method of sourcing the obsidian was conducted using portable X-Ray Fluorescence (pXRF) analysis on several hundred pieces of obsidian from six archaeological sites. In combination with pXRF, macro-analysis of obsidian artifacts was conducted to determine form, use-wear, and potential function. The two main goals of the study are to understand (1) the networks of trade and exchange both on a micro- and macro-regional scale, and (2) the production and use of obsidian objects within and between neighboring archaeological sites through time. This analysis of the distribution and use of an exotic prestige item such as obsidian allows for a more detailed assessment of social and economic interaction within the region.

Rice, Sarah
[166] Paleoindian Land Use and Mobility in the Carson Desert, Western Nevada
The Paleoarchaic record is poorly represented in the southern Lahontan Basin and this is in part because of avocational artifact collecting, incomplete survey coverage, and restricted land access. In the winter of 2011, Far Western Anthropological Research Group, Inc. located a unique upland Paleoarchaic site, 26CH3413, (The Seal Beach Overlook Site) while conducting pedestrian survey on Naval Air Station, Fallon, in Churchill County, Nevada. The site is a large lithic scatter located atop a promontory on the east side of the Dead Camel Mountains and the north end of the Desert Mountains. The surface assemblage contains numerous lithic tools and more than 1,000 pieces of debitage. Formal tools are noticeably denser in two areas of the site, indicating the surface assemblage retains a degree of spatial patterning. The site’s central sand sheet contains abundant artifacts, suggesting subsurface cultural deposits that may preserve buried features. Here I present the results of fieldwork at the site and preliminary analysis of the tools.

Richard, Andrew (University of Arizona)
[166] A Comparison of Fluted and Stemmed Projectile Point Strength Using Porcelain as a Medium
Projectile point breakage provides researchers with valuable information on hafting style, projectile point strengths and weaknesses and other valuable data. This study compares the different types of breakage between PaleoIndian fluted and stemmed projectile points to determine their strengths and weaknesses. The goal of this study is to ascertain the breakage characteristics of each style of point, the frequency of breakage, type of breakage and consistencies in the area of the break to determine which projectile point is stronger. Comparisons of fluted and stemmed traditions could shed light on transitions in projectile point morphology. To answer these questions a procedure was developed using porcelain to cast projectile points consistently, in large quantities, that mimic the characteristics of stone while increasing experimental control. Stone has inherent problems involving production time, production numbers, consistent morphology and expense when attempting to flintknap large quantities of projectile points. In this study, fluted and stemmed points will be cast in porcelain, hafted to foreshafts, and then broken from different angles in order to quantify variation in fracture patterns.

Richard, Francois (University of Chicago)
Elite control over property, production, economic surplus, and long-distance trade is centrally featured in
archaeological scenarios of political complexity. As Susan McIntosh remarks, however, such was not the case in many parts of pre-colonial West Africa, where the widespread availability of land, combined with relatively small, mobile populations, pose material headaches for would-be rulers. Here, conventional notions of dispossession, scarcity, and accumulation by themselves fall short of capturing the subtleties of political economy; rather, mechanisms rooted in a broad ethos of abundance – collective ownership, horizontal redistribution, wealth in people/knowledge, compositional forms of consumption – subtended the economic strategies of peasants and aristocrats alike. Using elements of Bataille’s ‘general economy,’ which draws on ideas of excess, dissipation, waste, and sacrifice, I examine broad trends in the relationship between labor, wealth, and social power in northern Senegal during the past millennium, and how these relationships were materialized in archaeological landscapes.

[270] “All Lie Down Together and Are Soon Forgotten”: The 2013 Milwaukee County Poor Farm Cemetery Project

Excavations at the Milwaukee County Institutional Grounds (MCIG) in Wauwatosa, Wisconsin in 1991 and 1992 recovered 1649 individuals associated with Milwaukee County’s practice from the mid-1800s through 1974 of providing burial for institutional residents, unidentified or unclaimed individuals sent from the Coroner’s Office, and community poor. In 2013, Historic Resource Management Services of the University of Wisconsin-Milwaukee recovered an additional 650 individual coffin burials from the MCIG. Burials recovered during the earlier excavations are predominantly single interments with an occasional extraneous body part representing incidental amputation or autopsy. However, the 2013 excavations include a high proportion of multiple interments composed of complete individual skeletons as well as body parts likely reflective of autopsy and medical school cadaver use. In addition, many graves contained debris consisting of general refuse and/or medical waste. This shift is likely associated with dramatic land-use changes resulting from the development of the MCIG property from a general county facility to its current use as home to the Milwaukee Regional Medical Center and the Medical College of Wisconsin. This paper presents the results of a land-use history of the MCIG site in order to contextualize differences in burial practices observed in different parts of the cemetery.

[154] LiDAR Applications for Landscape Archaeology: A Case Study from Copan, Honduras

Airborne LiDAR opens up new research avenues, particularly in landscape archaeology where the rapid acquisition of high-resolution 3D data across vast landscapes and in impenetrable terrain allows archaeologists to contextualize larger (often already known) sites and perform regional analyses. This paper presents LiDAR data from Copan, Honduras flown for the MayaArch3D Project in May 2013 and the results of a ground-truthing campaign in January-March 2014. By comparing settlement maps and a Digital Terrain Model (DTM) derived from a 1980s pedestrian survey with new settlement maps and a DTM based on the LiDAR data, this project can contribute new accurate data to the existing topographic plans and terrain models, enabling the researchers to perform analyses with requirements for high accuracy like visibility and orientation studies. To assess the impact of increased mapping accuracy for archaeological research, we perform a sample visibility analysis among a sub-set of settlements. While LiDAR data expands the ways in which archaeologists study how past peoples constructed, shaped, and made use of their environment, we emphasize the value of and need for pedestrian survey as a critical component of landscape archaeology.

Richter, Kim ( Getty Research Institute)

[62] The Iconography of Postclassic Huastec Sculptures

The most frequent subject matter of Postclassic Huastec sculptures is the human form. Male and female figures, probably nobles, are represented in a standardized way: standing either in the standard-bearer pose or with the hands on the abdomen and wearing elaborate costumes. Those with the greatest artistic
merit are masterfully elaborated with surface details, drawing attention to the bodily adornments, in particular the headress. The analysis of Huastec sculptures reveals iconographic links to Postclassic artworks from other regions, such as other artistic traditions along the Gulf Coast and the painted codices from Central Mexico. These links confirm that the sculptures date to the Postclassic (A.D. 950–1521) period. Inscribed with a regional variant of the visual vocabulary shared throughout the Postclassic elite interregional network, Huastec sculptures legitimized local rulership by advertising external cultural ties. These remarkable sculptures provide insight to how the Huasteca fit into the cultural fabric of the Postclassic Mesoamerica world system.

Evidence for the Role of Plazas at Chavin de Huantar, Peru

The Formative site of Chavin de Huantar, Peru, has long been recognized for its iconic plazas, thought to be the ritual focus of successive architectural arrangements at the site. Plaza-like areas are more varied at Chavin than previously thought, and the evidence for their use is similarly complex. The evidence for ritual use of these spaces is discussed, including that for the number of people involved, the nature of the activities performed there, and change over time in plaza function.

Rick, Torben (Smithsonian Institution)

Oysters, Foxes, and Everything in Between: Reasserting the Importance of Chronology Building in Zooarchaeology

Zooarchaeologists have increasingly focused on issues of taphonomy and preservation as we have asked more sophisticated questions about human animal relationships and changes in faunal assemblages. An important aspect of this research is the reliability of the age estimates for a given faunal assemblage or individual bone or shell. In this paper, I draw on recent research focused on the translocation of mammals to the California Islands and the harvest of shellfish along the Chesapeake Bay where chronology building has been a core component of each project. Radiocarbon dating of bones and shells from a variety of different sites and contexts revealed evidence for stratigraphic mixing and other disturbances not recognized during excavation or previous chronology building and helped raise questions about the reliability of some of our interpretations. While archaeologists have long recognized the importance of having reliable radiocarbon chronologies, the growth of historical ecology and applied zooarchaeology place new emphasis on the need to devote greater resources to this important issue.

Riddle, Andrew (Archaeological Services Inc.) and Amy Fox (University at Albany, SUNY)

Wiki Technology in Service of Archaeology

Our discipline has entered the digital age and is beginning to take advantage of new resources at our disposal. Wiki technology is one such resource that can be effectively leveraged to disseminate key information about the discipline, facilitating collaborative learning and research. The wiki framework is well-suited to archaeology because the discipline's subject matter - method, theory, material culture - is readily organized into interrelated 'articles.' Content is searchable via user-defined attributes such as temporal period, geographic location, and cultural affiliation. This aspect of wiki technology uniquely facilitates an understanding of topic interconnection, and the platform has great potential as a peer-driven forum for information dissemination and discussion that is accessible to all interested parties. To this end, the ArchaeoWiki Project has been designed to test this medium and is structured to accommodate an ever-growing body of archaeological knowledge. ArchaeoWiki moves beyond traditional wiki functionality in order to address the needs of the scholarly community, incorporating a robust, queryable reference database and dynamically-generated content into its existing framework. With this structure in mind, it is argued that wikis can be forums for sharing knowledge and, most importantly, become destinations for engagement with others interested in the discipline of archaeology.

Rideout, Jennifer (Missouri State University)

A New Method of Ceramic Economic Indexing in Historical Archaeology: A Case Study from Springfield, Missouri
The goals of this research are to develop an empirical method of quantifying post-Civil War household ceramic expenditure patterns based on archaeological remains, and apply this new method to a case study from historic Springfield, Missouri, to investigate socioeconomic inequality and consumerism in the Ozarks and broader Midwest at the turn of the twentieth century. I used historic mail order catalogs to develop economic indices of ceramics sold between the 1880s and 1920s. These indices were applied to historic ceramic assemblages from Springfield, to calculate the mean ceramic expenditure of households in several racially, ethnically, and economically distinct neighborhoods. In this poster, I present these new indices, show results of the archaeological application, and interpret the archaeological results in light of other, archival-based, socioeconomic status indicators.

Ridky, Jaroslav [299] see Kvetina, Petr

Riebe, Danielle (University of Illinois at Chicago) and Paul Duffy (University of Toronto) [222] Baroque by Whose Hand? Detailing the Regional Production of Finewares in Middle Bronze Age Hungary

The Early to Middle Bronze Age transition (2000-1500 B.C.) in Eastern Europe is characterized by a tremendous expansion in the trade of horses, ores, and finished metals. During the same time, finewares with a great number of new ceramic stylistic elements emerged in the middle of this trade nexus. Some scholars suggest the style on the Plain was the result of specialized products moving with a new mobile class of warrior elites. Others argue the distribution of these finewares was produced by a re-orientation of trade networks, but not by a smaller number of specialized producers. This paper presents the results of a recent study that uses Laser Ablation-Inductively Coupled Plasma-Mass Spectrometry (LA-ICP-MS) to compositionally analyze ceramic and clay materials from five Bronze Age sites across the Great Hungarian Plain. By ascertaining local clay signatures for each site, the primary goal of the project is to determine if local and imported ceramics can be identified. In doing so, we discuss the current evidence that Middle Bronze Age finewares were the product of a small number of specialized workshops controlled by a new minority class.

Riegert, Dorothy (University of Texas at Austin), Colene Knaub (Toledo University), Molly Roffers (University of Wisconsin- Oshkosh ), Andre Gonciar (ArchaeoTek) and Zsolt Nyaradi (Haaz Rezso Museum ) [102] A Biocultural Analysis of Infant Burials Interred at Telekfalva

The prevalence of perinatal individuals excavated from the Reform Church in the village of Telekfalva presents a rare opportunity to explore juvenile identity and the social role of infant burial in 17th century Transylvania, Romania. The assemblage of 49 infant burials recovered from the Reform Church fosters a discussion of why perinatal individuals, who were possibly unbaptized, were buried in sacred, consecrated space. Via the biocultural model we explore spatial burial data to recreate the dynamic relationship among these infants. We explore the role of this church as a designated space for infant interments and deviant burials while utilizing life-course analysis to examine the performed solidification of memory through mortuary practice as a possible means of baptism after death. We investigate the spatial relationship of burial position, the use or disuse of coffins, the inclusion of grave goods, and age-at-death data in order to extrapolate any relevant patterns. Following this analysis, we conclude that it is necessary to contextualize bioarchaeological data within a medieval historical framework in order to best investigate the pattern of infant burials observed at Telekfalva.

Riel-Salvatore, Julien (University of Colorado Denver) [71] The Uluzzian and the Epistemology of the Middle-Upper Paleolithic Transition

Long thought to have been manufactured by Neanderthals, the Uluzzian has recently been argued to be the earliest modern human technocomplex in Western Europe. While this recent reevaluation of its authorship has been questioned, the current revisions of what the Uluzzian might have ‘meant’ for the end of the Neanderthals opens up an interesting opportunity to examine what makes certain scenarios about the nature of transitional industries a priori more or less plausible. The question of ‘how we know what we know in the Paleolithic’ has been a recurring focus of Prof. Geoff Clark’s work, and the current supercharged state of Uluzzian research lends itself to an epistemological assessment to contextualize where our interpretations of that particular Paleolithic ‘culture’ come from, and to highlight potential tensions among them. This study presents a historical review of the Uluzzian, followed by a critical perspective on the ‘Uluzzian question’ that identifies a series of factors that may have biased to various degrees how this industry has been interpreted over the past 50 years or so.

[71] Chair

William A. Ritchie began his career as a curator and archaeologist at the Rochester Museum. In 1949, he accepted a position as State Archaeologist at the New York State Museum in Albany. He held this position until his retirement in 1972. During his tenure as State Archaeologist, he furthered New York archaeology through the excavation of more than 100 sites and published more than 150 papers in journals, books, and other scholarly publications. These excavations not only contributed to our understanding of regional settlement patterns but also helped to refine the chronology of the state’s earliest occupants. In addition, Ritchie also helped develop early laws for the protection of archaeological remains on state owned land, oversaw one of the earliest cultural resource management programs in the state, and worked with state agencies to advocate for the preservation of archaeological sites. His contributions continue to be visible today and his publications continue to be cited in studies of the past. This paper will highlight the many contributions made by Ritchie to the discipline between 1949 and 1970 and their impact on archaeology.

Variation and Similarities in Vertebrate Faunal Exploitation in Early Deposits from Fiji and Samoa

The prey choice model of optimal foraging theory (OFT) provides a means for measuring diet breadth and foraging efficiency, which can be used to examine variation in prey capture relating to resource exploitation/depression and/or environmental change. Using this model, we track temporal changes in vertebrate faunal collections (overwhelmingly bony fish) from early deposits in Fiji (-2700-2300 cal. B.P.) and Samoa (2550-2195 to 2260-1876 cal. B.P.). The Fijian collection from Tavua Island, Mamanuca Group, includes Lapita and post-Lapita remains, while the Samoa collection comes from an early Polynesian Plainware deposit from Tula Village, Tutuila Island. Both collections document exploitation of pristine, or near-pristine, marine and terrestrial ecosystems. Whereas geographical variation has been noted in specific fish taxa present in Fijian Lapita deposits with an increased number of taxa captured in later centuries, previous analyses of Samoan material documents temporospatial stability in marine predation. Our results, therefore, are relevant for examining local and regional variation and commonalities in human predation of vertebrate prey, and how these activities interacted with, and adjusted to, dynamically changing environments.

Seasonal Plant Community Use by Late Prehistoric Hunter-Gatherers in the Eastern Trans-Pecos Archaeological Region of Texas

The Eastern Trans-Pecos archaeological region of Texas is an area of unique prehistoric cultural assemblages and high ecological variability, yet few analytically quantitative studies investigating human-environmental relationships have been undertaken. Research described in this paper augments the quantitative literature for the region. This analysis focuses on the Late Prehistoric (A.D. 1000—1535) period of the region to determine prehistoric seasonal plant community use. Using geographic information systems (GIS), United States Department of Agriculture–Natural Resource Conservation Service (USDA-NRCS) plant community descriptions were ranked by seasonally available native plant foods based upon recorded Mescalero Apache native plant diet. These data were then compared to published paleoethnobotanical dietary information from archaeological sites in the Eastern Trans-Pecos coupled with accessed plant communities determined by reconstructed foraging radii. Results indicate that plant community use by Late Prehistoric hunter-gatherers fluctuated seasonally and that use of USDA-NRCS plant community descriptions is well suited for examining human-environmental interactions in recent prehistory.
An Exploration of Marks on Extinct Sloth Bones and Lithics from a Flooded Cavern in the Dominican Republic

In June 2010, a dive team from the Indiana University Office of Underwater Science recovered numerous sloth remains from Padre Nuestro, a flooded cavern in southeastern Hispaniola. Due to the deteriorating condition of the remains, the assemblage was treated with PEG 4000 for preservation purposes. Previously identified sloth remains from this cavern include the extinct species Acratocnus ye and Parocnus serus. Attempts to date the bones have been unsuccessful. Casimiroid lithics and Chican ostionoid ceramics, also found in the cavern, indicate utilization of Padre Nuestro by the first peoples of the Caribbean and the late pre-contact Taíno. Faunal elements, including humeri, vertebrae, femurs, ulnas, and innominate, rib, sacrum, and scapula fragments present possible cutmarks. It is assumed that prehistoric inhabitants of the Caribbean hunted sloths into extinction; however, no direct evidence has been identified. This poster will show a comparison between macroscopic, microscopic, and SEM photographs of the markings in order to explore their origins.

Incised Stones and Unsecured Localities: Authenticating Private Collections

The Prehistoric Museum at Utah State University Eastern has a collection of sixty-three incised stones donated by private individuals in the early 1990s. These artifacts, collected during the 1960s and 1970s, supposedly came from a rockshelter located near Fish Springs National Wildlife Refuge along the southern edge of the Great Salt Lake desert. The donated collection also includes an associated projectile point, basketry fragment and several other perishable objects. This presentation will focus on the problems associated with conducting research on museum collections with limited provenience data. Many of these stones have very precise, uniform walking or “rocker” lines. Attempts to replicate these lines with a variety of traditional and modern methods will be compared. Additionally, element analysis of the broad variety of designs in the collection may shed light on the claim that this is a single, authentic assemblage. The results of the design analysis and manufacturing experiment will be compared with excavated incised stone assemblages from three sites in neighboring Tooele and Millard counties. Further examination of the associated projectile point and perishable materials may expand our incomplete understanding of this assemblage.

The Struggle for the Indian Soul: Zoological and Botanical Imagery in the Conversion to Christianity of the Native Peoples of the Mixteca Alta of Oaxaca.

This paper focuses on the belief system and ideological underpinnings upon which Post-Classic native polities in the Mixteca Alta of Oaxaca were organized. Beginning in the 1530’s, the vice-regal religious authority was charged with the extirpation of native religious practices. This effort would challenge the existing worldview and social order and as new technologies were introduced and adopted, the outbreak of pandemics and the forced relocation of the population into nucleated pueblos transformed the culture and the land. The manipulation of beliefs, by selecting indigenous zoological/botanical representations as metaphors for behavior, served to further the causes of the invaders while providing cognitive consonance and stability for the local inhabitants during a time of great stress in their transition to a Christian, colonial experience.

Daily Life and Highland Identity in a Gallinazo-Early Moche Phase Community in the Moche Valley, Peru

Sociopolitical change during the Early Intermediate period led to development of the Moche polity centered at the Huacas de Moche on the coast, yet settlement patterns inland indicate a strong highland presence prior to and possibly overlapping with the Moche emergence on the coast. Previous explanations focus on trade or migration to account for the predominance of a highland-style pottery assemblage at many middle valley Gallinazo and Early Moche phase sites. I evaluate questions of cultural identity and social dynamics in three middle Moche valley households at Cerro León (C.E. 1 to 400). My study of the pottery assemblage, including vessel function, petrography and raw materials analysis, demonstrates that migration and multi-generation settlement is a plausible explanation. Highland pottery was integral to particular activities, especially feasting, spinning, and certain daily food processing and storage activities. The majority of the vessel assemblage consists of highland pottery fabrics and distinct vessel forms that lead to the conclusion that Cerro León residents were of highland
origin and chose familiar products for daily and feasting activities.

[142] Galleons, Temples, and Beads: Early Euro-Native Cultural Interactions at Two Harbors (CA-SCAI-39)

Diary accounts from Sebastian Vizcaino’s sojourn at Santa Catalina Island in 1602 presents a rare glimpse into one of the few documented ship landings on California shores during the Protohistoric Period. The narratives consist of vivid accounts of the Spaniards’ interactions with natives at the large Village of Nájquqar (Archeological Site CA-SCAI-39) known today as Two Harbors. The Spaniards mention visiting a temple and exchanging glass beads and “other trinkets” with the natives. In 1875 Paul Schumacher of the Smithsonian Institute excavated numerous Spanish artifacts from burials at Nájquqar, including glass beads, Catholic medals, Spanish bowls, and a sword, all of which are all still in excellent preservation today. Salvage excavations by UCLA in 1969 still provide new insights about the significance of Nájquqar. Current research delves into the substantial amount of Native American trade items and European artifacts to look at the nature and duration of this relationship. Many of the artifacts in these excavations may represent well documented historic ship visits to Two Harbors by the crews of such ships as the Leila Byrd in 1805. This presentation will discuss ongoing research on these early Euro-Native cultural exchanges during a dramatic and important period of American history.

[31] The Genesis of Social Complexity in the Puuc Hills of Northern Yucatan, Mexico

Narratives concerning the origins of Maya civilization, whether interpreted as the appearance of the earliest agriculture communities or the initiation of monumental construction, have tended to privilege the southern lowlands. Framed in this fashion, such narratives also imply the genesis of a common ethnicity in conjunction with these material manifestations, particularly the spread of the Mamom ceramic sphere during the Middle Formative period. This paper reviews recent evidence for Middle Formative settlement in the eastern Puuc Hills recovered by the Bolonchen Regional Archaeological Project. Formerly considered nearly uninhabited during the Preclassic, the Puuc Hills must now be viewed as yet another region of the northern lowlands undergoing dramatic social transformations very early in the Middle Formative, if not earlier. The implications of this evidence for questions of identity formation are then assessed in light of ceramic and architectural affinities to other Early-Middle Formative traditions.

[33] Visualizing Cave Architecture along the Central Coast of Quintana Roo, Mexico

Innovative imaging and visualization techniques allow for the capture and display of features or objects within their broader spatial contexts. With respect to Maya cave architecture, high-resolution panoramic visualization can be a powerful analytical tool, enabling the evaluation of potentially meaningful relationships between natural features – be they entrances, pools of water, or speleothems – and
constructed features within a cave. Given their remarkable stylistic correspondence to Postclassic temple architecture, cave shrines and altars provide compelling and unambiguous evidence for religious practice in the cave environment. Initial comparative and multiscale analyses across terrestrial and subterranean environments – facilitated, in part, by specific visualization techniques – provide insight into the form, function, and meaning of Postclassic cave architecture in the northeastern Maya lowlands.

Investigating Community Organization: Spatial Distributions over 4000 Years on Sapelo Island, GA

The Native American occupation of the Kenan Field site (9MC67) spans nearly 4000 years. Kenan Field is located on Sapelo Island along the Georgia Coast, and pottery from every major time period from the Late Archaic to the Mission period is present. Using shovel test survey, excavation, and geophysical data collected in 2013 by the University of Georgia, I offer a preliminary discussion of its implications for understanding activity areas and monumental architecture at the site. This work forms the basis of a long-term study designed to investigate the changing nature of political systems and strategies on the Georgia Coast.

Faunal Remains from Two Heartland Inka Sites

In the highland region of Peru, the Inka employed diverse strategies of domination over neighboring groups. At Cheqoq, in Maras, the Inka forced the Ayarmaka to abandon their land and replaced them with resettled provincial laborers. At Ak'awillay, the Inka allied with the Anta and treated them as Inkas-by-Privilege. Recent test excavations (2012) at Ak'awillay allow us to look at site subsistence practices before and after Inka rule through faunal analysis. We examined taxonomic frequencies as well as meat yield and herd management patterns. We compare and contrast Ak'awillay and Cheqoq to see subsistence patterns and possible ritual use of fauna at two heartland sites. Both the Cheqoq and Ak'awillay sites show diets that were primarily made up of camelids and guinea pigs, with less frequent occurrences of wild and exotic fauna. This comparison was done in order to determine the differences between the domestic economies of households serving the nobility as retainer laborers (Cheqoq) and a group who had more freedom within the heartland (Ak'awillay) as allies of the state. Cheqoq shows differences in diet between households, while our data from Ak'awillay are not yet as clearly distinguishable.

Chile and the XIX Century European Human Zoos

During XIX century members of different ethnic groups from Southern Chile were taken to Europe in order to be exhibited in “human zoos”. They could not be considered as kidnappers because the Chilean government consented to the operation. Several cases are presented, among them, that of Calafate, a young Selknam boy that was taken in 1889 (along with a group of nine other people) and only survivor who returned to his homeland, and the repatriation of remains of five Kawesqar people from Switzerland who were part of a group of eleven members that were taken from Patagonia in 1881 by Carl Hagenbeck. The presentation will introduce one of the last descendants of the Kawesqar ethnic group who speaks the language and who witnesses the tragedy of the Fueguian people.

Human Adaptation Strategies of Abrupt Climate Change ca. 3.8 kya
Then Archaic period in the Caribbean (ca. 5ky -1.5ky BP) presents an intriguing case study for the understanding of the socioenvironmental dynamics surrounding initial human occupations of tropical islands. The climate record of the end of the Mid-Holocene and the beginning of the Late Holocene in the Caribbean shows high variability and intense hurricane activity. So far, the archaeological record of the period suggests social continuity throughout the period. However, much of the information is coarse grained and large scale. Little research has been conducted on the local effect of climate variability or on the adaptation strategies or social responses to change at smaller scales. This study explores how people responded to climate change at the microscale and what adaptation strategies were implemented, if any. To these ends, we articulate high resolution speleothem data of abrupt climatic variability within the hydrological basin of the site of Angostura, one of the earliest archaeological sites in Puerto Rico, with archaeomolgical and geoarchaeological data from the site and its surrounding landscape. The study emphasizes the importance of considering scale when evaluating environmental data, and the possible existence of multiple coeval social adaptation strategies within individual occupation periods.

[126] Retheorizing Inequality and the Body
We cannot write a history of the body without considering inequality or a history of inequality without considering the body. Archaeologists usually argue that political inequality is visited upon the body through differential health, nutrition, stress or violence. This reproduces a theoretical divide between a “biological” body and a “social” body by treating the body as a blank canvas for society to write upon. This paper draws upon feminist theory, concepts of the body as social capital and examples from later European prehistory to show how the different bodies produced by inequality become social agents generating social relations and history.

Robbins Schug, Gwen (Appalachian State University)
[67] A Hierarchy of Values: Order, Complexity, and Agency at Harappa
In the third millennium B.C., the Indus Civilization flourished in northwest India and Pakistan. Part of the Persian Gulf interaction sphere, Indus cities exerted cultural and economic influence over 1,000,000 square kilometers of territory. Shifts in these economic relationships occurred at the end of the second millennium with increasing aridity, a weakened monsoon system, and increasingly high levels of hydro-climatic stress in the Indus River system (1900-1700 B.C.). I examined the biological consequences of climate change and socio-economic disruption, and a weakened state in the post-urban period at Harappa, one of the largest urban centers of the Indus Civilization. Bioarchaeological evidence demonstrates the prevalence of violent injury, infection, and infectious diseases increased through time. Furthermore, mortuary analysis supports the inference that the risk for infection and disease was uneven among burial communities. Socially and economically marginalized communities were most vulnerable in the context of climate uncertainty at Harappa. Our data suggest a growing pathology of power in the post-urban period of this increasingly incoherent state. Observations of the intersection between climate change, social processes, and pathology in this proto-historic city is interpreted in the larger context of vulnerability, insecurity, and state power in the face of climate change.

[316] Prehistoric Felsite Procurement and Use in the Twentynine Palms Region: Perspectives from Recent Site Evaluations at the Marine Corps Air Ground Combat Center and in Upper Johnson Valley, California
Early-Middle Holocene hunter-gatherers throughout the Great Basin and Mojave Desert preferred durable fine-grained volcanic (FGV) raw materials to manufacture a variety of tools. Archaeological investigations conducted over the last 15 years in the southwestern quadrant of the Marine Corps Air Ground Combat Center (MCAGCC) and adjacent portions of Upper Johnson Valley near Twentynine Palms, California, indicate that plutonic felsite quarried from local sources in the Hartwell Hills was also preferentially utilized by Early-Middle Holocene hunter-gatherers. This poster presents a summary of currently available data regarding felsite procurement and use at MCAGCC and in Upper Johnson Valley, highlighting recent test excavations of quarry sites conducted by Far Western, and provides an assessment of these data within the broader context of early FGV procurement and use throughout the Great Basin.

[151] Recording Pull-Tabs and Barbie Dolls: Have Our CRM Methods Become Artifacts?

Thirty-five years ago when I began my career in contract archaeology the artifacts I recorded seemed old, or at least they looked like something I might see in my grandmother’s attic. Today, I am required to save GPS coordinates for all pull-tabs from beverage cans and Barbie doll parts, and in some states one of each, if located less than 30 m apart, is an archaeological site worthy of documentation. Can these data shed new light on the past and provide information important to history? Was this the intent of CRM laws and regulations? In this paper I examine the development of CRM in the Western U.S. from the perspective of an aging “New” archaeologist who in the 1980s enthusiastically helped create the system, and has been forced to use it—virtually unchanged—ever since.

[304] Changes in Consultant Archaeology

Archaeological compliance has changed dramatically in recent years. Archaeologists adapting to these changes require training unavailable in most graduate programs. Advanced knowledge of GIS and other digital data proficiencies is now required to operate in this professional environment. Northern Arizona University (NAU) is well known for its terminal Master’s program aimed at preparing students for the rigors of careers in cultural resource management (CRM). This paper discusses the changing face of compliance archaeology and the ways that the graduate program at NAU prepares (or does not prepare) students to become successful CRM professionals.

Robertshaw, Peter (CSU San Bernadino)

Colonial ethnography in Africa played a key role in the establishment of political anthropology, but subsequent global archaeological emphasis on the study of pristine states relegated African archaeology to the periphery of debates on the development of social complexity. McIntosh’s edited volume, Beyond Chiefdoms (1999), revived global interest in Africa, while Blanton’s Collective Action Theory has also provided a new framework for thinking about complexity in Africa. Lately African archaeologists have embraced ethnographic, ethnohistorical, and historical linguistic evidence to construct more anthropologically informed interpretations of the development of complexity. One result of this has been the recognition of the centrality of creative (ritual) power in African political systems. The challenge has been to identify this type of power in the archaeological record. I briefly present three case studies from different parts of Africa where archaeologists have been able to recognize the role of ritual power, but I focus mostly on Uganda where exploration of ideas of networks of public healing and knowledge reveal the complexity of social complexity. In particular such networks could at various times be used to either develop or inhibit attempts at establishing hierarchical political systems.

[63] Ceramic Evidence for Urban Subsistence Practices at Teotihuacan

As in most other pre-industrial cities, urban life at Teotihuacan was deeply entangled with ceramic technology, perhaps nowhere more strikingly than in the realm of food-ways. In this paper, we consider information from two different sources—ceramic residues and intra-site distributional patterns of potsherds—in an attempt to shed new light on the city's subsistence economy. We consider various forms of domestic pottery thought to be important in food storage and cooking practices, including distinct types of San Martín Orange, a ware manufactured in a large potters’ barrio on the southern edge of the city. Absorbed organic residue analyses aimed at identifying animal and plant remains in sherds derived from recent excavations in a range of contexts are used to evaluate both functional and social differences associated with these types. Spatial autocorrelation measures distilled from the surface collections of the Teotihuacan Mapping Project address similar kinds of differences at broader spatial scales.

Cerro Maya Ceramics Revisited

The Late Preclassic ceramics from Cerro Maya in northern Belize were initially analyzed as dissertation research in 1978-80. Thirty years later, the increase in the amount and quality of the comparative material from sites throughout Belize, Guatemala and Mexico necessitated a revision of the typology and the sequence. In this work the unusually high frequency of primary deposition events has shaped the chronology, but, more importantly, made possible a focus on the role of function and context in the classification of the ceramic material. That focus has been enhanced by the digitization of the records and catalogs from the site undertaken by Debra Walker. Her work has enabled the integration of various data bases with the ceramics, all of which were excavated in an environment without electricity and recorded and analyzed with paper and pencil. The resulting model has implications for our understanding and documentation of the Late Preclassic Maya ceramic system of production, use and disposal of pottery, illuminating the private and public domestic and civic activities that were essential to the economic, political and sacred world order as the Maya elite consolidated their authority and status.

How Recording Techniques Impact Our Knowledge of Neolithic Tomb Art: The Example of Sardinian Rock-Cut Tombs

The aim of this paper is to show how new recordings using diverse photographic techniques can significantly change our empirical knowledge of Sardinian decorated tombs. As for many rock art sites around the world, such standard modern techniques, never used before on the island, allow to revaluate already known motifs and to discover unknown motifs that are not visible with the naked eyes. Two case studies from recent fieldwork will be presented to illustrate this. The rock-cut tomb of Pubusattile 4 in Villanova Monteleone, where DStretch processing of photographs has shown new details of a painted panels and helped producing a much more accurate recording than the one published in the early 1990s. The second example is Tomba Maggiore in the S’Adde ‘e Asile necropolis in Ossi, where a recent photographic survey of the art using the VeDPOL technique has resulted in the discovery of 8 carved bull- head motifs that were unsuspected before despite frequent visits on the site. A generalization of such photographic surveys and recordings has a big potential in Sardinia where about 250 decorated tombs are known, including 65 that have never been visually recorded.

Exchange Networks and Early Holocene Ecological Change in the Southern North Sea Basin

This presentation honors Mike Jochim’s contribution to our understanding of the relationships between diachronic changes in ecology, land use, and exchange in the European Mesolithic. It focuses specifically on the long distance exchange of quartz arenites between the Paris and North Sea basins throughout the Mesolithic. During the Early Mesolithic period two distinct quartz arenite types were procured from the same outcrop region in central Belgium and distributed to different geographical regions where they were differentially utilized within different technological systems. The Middle Mesolithic witnessed the consolidation of these different industries, the disappearance of one variety from the archaeological record, and the increase in the distribution of the other variety to 80,000 km2. These changes occurred between two abrupt climate change events and the final inundation phases of the southernmost North Sea basin. This presentation proposes the hypothesis that these changes facilitated the development of a
social network that enabled hunter-gatherers to cope with a period of considerable inter-regional environmental variability and uncertainty.

Robinson, David (Texas Archeological Research Lab, UT-Austin)
Petrographic data from East Texas ceramics and from surrounding regions has been produced on a project basis controlled by the needs of cultural resource management, since the early 1970s. Syntheses of the data employed few quantitative comparisons, but remained on a summary discussion, or previous work review, basis. Comparative syntheses of greater validity have slowly emerged, since 2000. Research goals have been directed to cultural issues of locality of manufacture, cultural interaction, postmanufacture function, and trade in raw materials and finished ceramics. Greater attention to sedimentology and petrology of the East Texas geological zone can give more precision to research findings in these study areas, particularly with regard to particle sorting and detrital minerals. New research findings support this position. Additional combined research in tandem with Instrumental Neutron Activation Analysis (INAA) provides a valuable research direction for the future.

Robinson, Mark (Louisiana State University)
[277] Building Identity at Las Cuevas: Architectural Excavations in Plaza B
The site of Las Cuevas located in the Chiquibul reserve centers around a large cave system with a small to medium sized site core positioned directly above the cave. The architectural layout is closely linked to the natural landscape, incorporating elements that reveal the function and identity of the site, including a ballcourt as well as two plazas, surrounded by temples, range structures, and low linear platforms. In this paper excavations in Plaza B, at the ballcourt and a series of linear structures that ring the lip of the sinkhole, are discussed in terms of form, function, landscape and identity.

[321] Hardware with no Software: The Rapid Late Adoption of Ceramics in the Highland Jornada Mogollon of Southeastern New Mexico.
This paper considers from a comparative perspective the spread of ceramics and the widespread but highly variable pattern of a two stage adoption of pottery: an initial sparse “software horizon” followed by a transition to intensified production of more durable pottery. It first illustrates this multi-step pattern not just as an issue in the initial invention of pottery technology but as relevant particularly to later cases of the adoption of ceramic production. Second, it summarizes a set of examples from the U.S. Southwest and adjoining areas to demonstrate variation in the software horizon pattern as well as highlight some of the implications of that variation for archaeological detection of ceramic use. Finally, it suggests that the multivariate nature of pottery technology and the low visibility of the software horizon has implications regarding variation in early Southwestern farming adaptations, and applies this observation to argue for a shift in settlement patterns--but not necessarily agricultural investment--associated with the mid sixth century A.D. appearance of pottery at Jornada Mogollon settlements in the highlands of the Southeastern/Central New Mexico.

Rochette, Erick (Indiana University of Pennsylvania)
Throughout his career investigating the origins and organization of Maya civilization, Norman Hammond continually revisited the changing role of jade in ancient Maya societies. Hammond's research at Cuello, Nohmul, and in northern Belize contributed greatly to our understanding of the role of jade as a symbolic representation of Preclassic Maya cosmological beliefs and social distinction, as well as the evolving systems of ancient Maya political, economic, and social structure. Just as importantly, his role in early efforts to characterize mineralogical signatures of jade from the Motagua Valley source region proved foundational to our current understanding of ancient Maya economic systems. The present paper examines our current understanding of the role of jade in Preclassic Maya society and the ways in which new archaeological, geochemical and other data have grown from the foundational contributions made by Norman Hammond.

*A Functional Perspective on the Organization of Mobile Toolkits during the Paleoindian Period*

Considerable attention has been paid to the organization of the mobile toolkit. Tool kit design, diversity, raw material choice, and the role of curation have all been major areas of discussion. What is often left out of this discussion, or inferred strictly from morphology, is the actual use of tools within a technology. This paper will explore the relationship between mobility and technology using a sample of artifacts from thirteen Paleoindian sites in New England and the Canadian Maritimes. The artifacts were examined using microwear analysis to assess their use. Particular attention is paid to the role of expedient technology within the toolkit, an area that has often been ignored in other technology discussions. This study sheds light on the relationship between technological use and mobility, especially the role of expedient technologies within the mobile toolkit.

*Fishing-Related Imagery and Ritual among the Gulf Coast Olmec*

Considerable research has been conducted on the practical and ritual importance of maize among Gulf Coast Olmec cultures, but much less attention has been paid to the importance of aquatic resources. Organic Formative Period artifacts are usually poorly preserved, but fragmentary stingray spines and jade effigies of shellfish have been found at La Venta; Gulf Coast Olmec sculptures depicting nets and fish-like creatures also provide evidence for analysis. Further evidence is found in enigmatic artifacts from Olmec sites and caches; while numerous interpretations have been suggested for these objects, systematic examination and replication studies reveal that these most likely functioned as luxury versions of everyday tools, such as net weights. Together, analysis of these data indicates that aquatic resources held considerable practical and ritual importance for these Formative period cultures.

*“Legitimate Practice”: Time, Space, and Power within Communities of Practice*

In this introductory paper I explore the relationship between spatial scales, power and the situated learning scholarship. I begin with a summary of Jean Lave and Etienne Wenger's (1991) work "Situated Learning: Legitimate Peripheral Participation" and its impact on archaeological research. Like others, I have found the situated learning literature as an ideal way to consider not just artifact patterning, but also the reproduction of culture, the emergence of shared skillful bodily practices and networks of relational communities. Yet archaeologists considering learning and material patterning must do so with an awareness of larger spatial scales (what Wenger has called "constellations of practice"), and the potential power differentials inherent in learning communities. Lave and Wenger remind us that power relations both enable and constrain the process of "peripheral participation," and the movement into a particular community of practice may also include the "truncation" of particular possibilities. I explore these issues in my ongoing archaeological work on Formative Period settlements in the Lake Titicaca Basin, and ethnographic work in a specialized potting community in this same region of highland Bolivia. I use these case studies to specifically consider how "non-elite" actors produce political landscapes within contexts of everyday learning.

[276] Material Culture on the Northern Frontier of La Florida
Between 1566 and 1568, expeditions led by Juan Pardo established six forts and related settlements in the Carolinas and eastern Tennessee, as part of an effort to establish permanent settlements along an overland route connecting the Spanish colonial province of La Florida with New Spain and the silver mines near Zacatecas, Mexico. Pardo’s principal outpost was composed of Fort San Juan and the associated town of Cuenca, both built at the Native American town of Joara, at the northern edge of La Florida. The remnants of Joara, Cuenca, and Fort San Juan are located at the Berry site, in the upper Catawba River Valley of western North Carolina. This paper discusses the assemblage of sixteenth-century Spanish goods found at the Berry site; and it compares those finds with artifacts found at Santa Elena, the origin point of the Pardo expeditions in coastal South Carolina, and itemized lists of provisions issued to the Pardo expeditions and the forts they built. Sixteenth-century Spanish goods from the Berry site demonstrate innovation, improvisation, and impoverishment, and they contribute to our knowledge of life on the frontier of La Florida at the end of the period of Spanish entradas in the Southeast.

[199] Ongoing Investigations at Two Dry Rockshelters in Eagle Nest Canyon
Investigations of two adjacent rockshelters in the Lower Pecos Canyonlands, Skiles Shelter (41VV165) and Kelley Cave (41VV164), seek to evaluate and tap their research potential. Both shelters have Pecos River style rock art and additional indications of contemporaneous use. The talus slopes of both shelters are strewn with fire-cracked rocks, obvious evidence that they served as earth oven facilities for baking desert succulents. Small-scale excavations in Skiles Shelter revealed disturbed upper cultural deposits resting atop a thick flood-deposited alluvium from the nearby Rio Grande. Beneath this were relatively homogenous midden deposits containing large amounts of charred fuel wood and food plants. Small-scale excavations at Kelley Cave encountered intact layers of ash and earth oven refuse. Numerous artifacts were recovered including Late Prehistoric to Middle Archaic points, scrapers, and flakes with traces of red pigment. Investigations also uncovered a modified surface, consisting of burned and cut leaves and other fibers covered by a smooth layer of fine-grain sediment. The numerous bedrock grinding features in Skiles Shelter and the extensive fiber materials found in Kelley Cave may reflect differential shelter use by hunter-gatherer populations. Radiocarbon dating and analysis of the materials recovered from both shelters is in progress.

[200] Archaeology and Ethnology, Different Paths toward the Same End: Approaching the Huichol deity Águila Joven through Material Culture
In archaeology we rarely have the opportunity to verify the truthfulness of our interpretations, especially when they involve the cosmovision of extinct populations. Yet we know that the study of material culture is not limited to these populations: it applies to societies of any time and place. Making use of this idea, this study contrasts ethnographic and archaeological data, in this case concerning the interpretation of a
Huichol deity known as Aguila Joven identified in the context of Chalchihuites, Zacatecas (A.D. 650-800). The objective of this comparison is to verify the accuracy of archaeological interpretations regarding the cosmovision of Prehispanic societies. First I discuss the material culture with the image of Aguila Joven and the interpretation that archaeology could gather from it. I then compare it with data from Huichol ethnography performed by others and by me. In this respect, it is remarkable that both methods offer similar conclusions. This is important because it is seen as an example that validates archaeological interpretation even when oral or written sources are lacking. In summary, both archaeology and ethnography show that Aguila Joven is not limited to the celestial realm as traditionally described; rather, it is closely linked to the earth and to maize.

[13] A Bayesian Approach to Investigating Age-at-Death of Subadult Archaeological Samples

Mortality profiles of children from archaeological contexts provide a sensitive indicator of overall population success. Estimating the age that subadults perished is the first step in this assessment, with dental formation remaining the most accurate aging indicator for children due to minimal environmental impact. Even the most accurate method, however, is affected by “mimicry bias”, where the age profile of the target (ancient) population “mimics” the age profile of the reference population used to develop the age estimation method. Bayesian statistics and transition analysis can control for this bias in archaeological samples through calculating the average age that transition from one phase of development to another occurs, and then estimating the probability that someone of a certain age has a given phase of development based on a sample of individuals of known age. Here, robust age ranges related to the dental formation phases of Moorrees et al. (1963) were generated using a sample 1377 children of known age (Orthodontics Case File System, Maxwell Museum of Anthropology). These ranges can be used by bioarchaeologists and forensic anthropologists wishing to control for “mimicry bias” in their mortality profiles that rely on age estimation via dental formation.

Rogers, Jerry

[151] Honor Roll to Planning Process

Federal preservation of significant places originally focused on places of outstanding national significance. After WWII, federally sponsored development projects threatening the historical, architectural, and archaeological heritage of the United States led to the National Historic Preservation Act of 1966 and a network of State Historic Preservation Officers. Practical problems implementing the Act led to Executive Order 11593, requiring federal agencies to identify and plan for properties affected by their undertakings that met National Register criteria. This necessitated appointment of preservation officers and development of professional capabilities in federal agencies that had not previously needed them. Eventually the network of preservation officers grew to include tribes and local governments. Increased contracting for archaeological surveys, data recovery, and ethnographic studies, together with tax incentives to rehabilitate historic buildings significantly broadened private sector participation in the partnership. Statutory requirements for the National Park Service and the Advisory Council on Historic Preservation to “provide leadership” to this large and complex mix led to participatory approaches within general planning systems. The dual nature of the program as honor roll and planning system was inherent in the 1966 Act and it likely to continue indefinitely.

[287] Obsidian Hydration as “Diffusion-Relaxation”: A Polymer Model for the Hydration Process

A generally accepted physical model of obsidian hydration is currently lacking. We propose a model based on capillary action, describe the physical basis of the model, and show its applicability to obsidian hydration. We demonstrate that the model reproduces the observed time-dependence for water uptake in obsidian quite well. The model also provides a first-order fit to the sigmoid form of the concentration curve, but fine structure is not correctly represented, indicating a need for refinement. These initial data show that “diffusion-relaxation” models of obsidian hydration hold promise, and hydration models based
on polymer science are worth pursuing further.

[49] Using Meta-Data as a Basis for Analyzing Communities Archaeologically

Archaeological investigations of social groups are common, but they have often lacked the strength of analogical thread needed to successfully connect past communities to material culture in the archaeological record. This paper aims to do just that. First, I systematically analyze meta-data about variables of archaeological interest to establish patterns of how archaeologists have previously related material culture to group identity and social differentiation. Then, I develop a frame of reference for a GIS-based analysis of the Classic-period civic-ceremonial site of El Coyote, Honduras, and future work on similar topics.

[269] Pre-Columbian Toponymy in the Greater Antilles

Toponyms—or place names—are very important for examining past events as they provide us with a wealth of useful information. They often remain in place, as a type of fossil, centuries after the language they belonged to died and its speakers disappeared, indicating the actual presence, at some point in the past, of a specific linguistic / ethnic group. Even in cases when it is impossible to successfully interpret the meaning of a toponym, its structure—phonological and morphological—can give us clues as to its linguistic affiliation. Given that the pre-columbian circum-Caribbean formed an intricate and multi-directional network of trade and cultural influences whose complexity is not at this point completely understood, a methodical investigation of the toponyms in the region can help us make the distinction between cultural influences or trade, on one hand, and actual population movements, on the other, and thus elucidate some of the problems of successive migrations into the Greater Antilles. This study proposes a systematic presentation and analysis of the possible linguistic parallels between Caribbean toponyms and indigenous language families spoken in the contiguous continental regions, as well as their evaluation as possible sources of the incoming migrants.

[8] The Beginning of a Long Journey: Archaeology and Cultural Heritage Promotion along the Southeast Coast of Guerrero, Mexico

In this paper, I present the results of the Coasts of Guerrero Archaeological Atlas Project (2009-2011 seasons). I focus on an unexplored region along the Pacific coast of southern Mexico: the southeast coast of Guerrero extending from the Acapulco Bay to the Oaxaca boundary. The main objective of this project is to gain perspective on the archaeological remains in this region. Issues of cultural heritage conservation are essential for the local people as well as for the development of the project. Notwithstanding limited time and resources, I expose a set of problems and solutions concerning the initial systematizing of information from governmental databases, and decision-making in selecting potential sites or areas. Then, we use systematic explorations as an efficient means of site recording at a regional scale to generate repositories of significant information, not only for this research itself, but also for further cultural management work. Systematic explorations encompass a wide range of archaeological evidence from different periods and of different natures (Pre-Columbian sites with monumental architecture and rock art, for example). Work also included recording historical monuments, private collections of artifacts, and old manuscripts from a parish archive.

[197] Is That All You’ve Got? Social Complexity in Tisma, Central Pacific Nicaragua

The pursuit of a better understanding of the development of social complexity, with a focus on the Pacific Nicaragua chiefdoms documented in contact-period chronicles leads to less than spectacular monumental and ornamental remains. Data from the Masaya region indicates that there are clear differences among neighboring communities in terms of regional settlement patterns, development trajectories and artifact distributions from early on in the local sequence. It will be argued that chiefdom-level societies are possible even in the absence of monumental architecture and abundant fancy goods, though further exploration of how such chiefdoms functioned is warranted.
Roman-Ramirez, Edwin (The University of Texas at Austin) 

The majority of researchers who consider the process of abandonment at Maya sites concentrate on catastrophic events, such as natural disasters or warfare. However, Maya studies often overlook the slow and planned abandonment of ancient cities. This paper explores the Early Classic compound called El Diablo, located at the site of El Zotz. After being inhabited for almost two hundred years, El Diablo, the seat of the royal lineage, was abandoned and intentionally buried. This paper will propose three ways in which slow and planned abandonment is demonstrated through the archaeological record and materials recovered. First, El Diablo is surrounded by ravines that make it difficult to extend the boundaries of the city. Second, the altitude, 190 m above the Valley of Buena Vista, make it difficult for the inhabitants to access water and farm the land. And third, this paper will propose that slow abandonment at El Diablo might be related to a period of peace in the Central Peten following the arrival of the foreigner Siyah K’ak, which created a perfect atmosphere for the ruler at El Zotz to move the city to the valley of the valley of Buena Vista.

[32] Corrugated Wares and Their Potential Use as Identity Markers at the Harris Site

The original typological system of corrugated wares that Emil Haury used based on his collection of sherds from the Harris site excavations in the 1930s did not incorporate much of the variability seen today. Excavation and curation techniques only allowed for a very small percentage of the corrugated wares to be collected and analyzed. Present techniques provide a much larger database, which can be used to expand current typologies through the variability seen in the corrugated wares recovered at a given site. This research focuses on corrugated wares recovered in various contexts from 20 pithouses and their associated features at the Harris Site, which have been excavated under the direction of Dr. Barbara Roth during the 2008-2013 field seasons. Numerous partially reconstructed corrugated vessels and a large corrugated sherd assemblage have been retrieved and are the basis of this study. A combination of hands-on and statistical analysis of these wares was used to examine the wide variability seen in current typologies and to determine if differences in corrugated wares from this site can provide information regarding identity in terms of how households may have varied the wares they produced.

[213] Diaspora, Displacement and Social Reconstruction: Reconceptualizing Diasporic Archaeology

This paper critically examines archaeological approaches to diasporic populations, integrating archaeology with contemporary cultural anthropology on social transformation, migration, and displacement. Historical diasporic studies follow models of population movements in antiquity “based on migration myths and …population flows” (Cohen 1995:1, Reis 2004:45). This classical model conflates diaspora with migration, a voluntary movement of a community (Guggenheim and Cernea 1993:3). This model, however, does not adequately address waves of displacement that accompanied European economic development of the New World. This development entailed one of the largest involuntary migrations in history. Enslavement and the African Diaspora more closely resemble modern development induced displacement than the classical diasporas of old. The theoretical orientation to the study of slavery, however, has often been focused on chronology and events, with an interpretive focus drawn from history. In this paper I contextualize how slavery in the southern United States was studied in archaeology and anthropology. I then review concepts of displacement and social reconstruction. I argue that slavery and its practice can be more clearly articulated as a process, with parallels to contemporary development, disaster and conflict induced displacement. These parallels provide a theoretical framework to better understand the social processes that existed in historic displacements.

Roos, Christopher (Southern Methodist University) 
[149] Identifying Human Impacts on Fire-Prone Landscapes

Using traditional paleoecological methods, it has proven surprisingly difficult to identify human impacts on natural fire regimes. This is particularly true for semi-arid fire-prone environments. Correlations between
changes in paleofire records and archaeological evidence or paleoclimate records can be ambiguous or misleading because human activities can amplify or suppress climate impacts on fire regimes. Traditional paleofire research has often focused on sedimentary locations and contexts that are ideal for preserving long, continuous microbotanical records regardless of the spatial relationship of the sampling locale to the ancient human landscape. Selecting sampling locales based on the location and distribution of archaeological evidence for human activities, however, offers scientists an opportunity to pair spatial comparisons with time-series comparisons of archaeological, paleofire, and paleoclimate datasets. Such a spatially explicit sampling approach offers distinct benefits for investigating fire-climate-society dynamics over long time-scales.

[282] Monte Alegre, Brazil: Remote in Time, Space, Scholarly Culture, and Culture History

Contrasting perceptions and experiences of remoteness arise in the minds of both ancient people and anthropologists. In the case of the Paleoindian culture of the Monte Alegre Serras in the mainstream Brazilian Amazon, people sought out rocky crags, caves, and rockshelters above the main floodplains and lakes for camping, foraging, stone-tool-shaping, rock-painting, and observations of heavenly bodies. Though western scholars long considered their tropical forest riverine habitat a wilderness remote from centers of human development, forest fruits and fish actually attracted migrants very early. Though physically remote from the probable first entry point of people into the Americas, the locality is in the center of a wide region where people of similar lithic culture roamed. And though remote from the best known Paleoindian cultures of western North America and South America, the Monte Alegre people were nearly contemporaneous. But the descendants of these early Amazonians did, in fact, keep their distance from some of the bio-cultural biological changes people experienced in other regions, thereby preserving more closeness to their ancestors than those in some other regions deemed more central, or nuclear, by anthropologists.

[119] The Intersections of Men and Power at the Alta California Missions

Contemporary discourse about men and masculinity in the Spanish colonial world is often connected to concepts such as machismo and linked to themes of sexual and social domination of European men over Indigenous Americans. Without denying the presence and effects of colonial Spanish patriarchy, I suggest that to be male in the colonial New World was a category of being shaped not only by one’s anatomy, but also by variety of factors, including known ethnic affiliation, marital status, and age. In mission-period California, the predominant male figure tends to be either the Spanish missionary or the Hispanic vaquero, despite being outnumbered by Indigenous men. My dissertation work at Mission San Antonio de Padua in Monterey County compares household labor practices in domestic quarters occupied, respectively, by single neophyte men, neophyte nuclear families, and mission soldiers and their families. Through the archaeological and documentary records and oral histories, I examine how different ideas about being male were enacted through daily life and illustrate how privilege and oppression could operate simultaneously for male members of mission communities.

[220] Ceramic Production on the Late Prehistoric Central Plains

Analysis of vessel form, descriptive and technological characteristics, and petrographic data for late prehistoric Central Plains pottery is allowing us to address how pottery production was organized and the material manufactured. We argue for local manufacture and household production, probably on an as-needed basis. Pottery clay was procured from alluvial sources near the household location, tempering material from unidentified sources that nevertheless are consistent with local lithologies. Processing of both clay and temper material was minimal and may have consisted of little more than removal of large clasts. Paste recipe and vessel design reflect a reengineering compared to earlier designs and are clearly affected by functional and performance considerations under conditions of increased use of cultigens and preparation of a diverse suite of foodstuffs. Vessel diversity was moderately high, and several of the functional classes were made in multiple sizes, probably for both utilitarian reasons and in
consideration of the social contexts of food presentation. A certain uniformity of manufacturing outcome but by no means standardization is evident. This may have begun to change by early protohistoric times as previously-dispersed people were aggregating into true villages.

Rorabaugh, Adam (Washington State University)

[173] Biederbost (45SN100) Re-examined: A Marpole Aged (2500-1500 B.P.) House Structure in Puget Sound

The development of large plank houses in the Salish Sea during the Marpole period (2500-1500 BP) has been central to theorizing issues of social inequality and resource use among complex foraging societies. In Puget Sound, two structures are known to date to this period of fundamental social transformations, Tualdad Altu and Biederbost. The Biederbost site, excavated by Astrida Blukis-Onat through Seattle Community College and the Washington Archaeological Conservancy in the 1960s and 1970s, has a wet and dry component. The wet site portion of the site has features interpreted as a fish trap while the dry site has post holes and hearth features that suggest a large house structure. However, the single date of 1940±80 B.P. had an unclear association with these two components. As part of a larger dissertation, eight new radiocarbon dates associated with hearths and post-hole features confirm that both components date to Marpole. An exhaustive re-examination of field records also supports interpretations of a large, likely household, structure. Despite recent re-evaluations of the temporal and spatial scope of Marpole in the Fraser Delta and Gulf Islands, it is apparent that large houses and their associated social transformations are also present in Puget Sound during Marpole.

Roscoe, Paul (University of Maine)

Ethnographic reports suggest that status competition is either universal in human society or very nearly so, and social-scientists have devoted a lot of attention to probing its forms (e.g., reputation, dominance, prestige, fame) and understanding why humans pursue them. Currently, though, hardly any empirical or analytical attention has been paid to a further issue. Why is status competition refracted into different forms – headhunting, say, as opposed to pig production, religious purity as opposed to consumerism? Evidence indicates that, in any one community, humans may accrue status through a range of channels, but a subset of these invariably receives particular cultural emphasis. Material distributions and warriorhood, for instance, seem to be especially prominent modes of status pursuit in small-scale societies, whereas consumerism is the favored channel in Anglo-American nations. Why do different communities emphasize different avenues to status? Within a community, moreover, what determines an individual’s pursuit of one mode rather than another? This paper presents data on status drawn from about 150 New Guinea communities, and suggests several factors to account for the differences.

Rose, Jeffrey and Anthony Marks (Southern Methodist University)

[26] The Origin of the Emiran and Implications for Modern Human Dispersal into the Levant

The origin of the Emiran industry is entangled with the question of modern human emergence. The Out of Africa paradigm predicts a population replacement in the Levant coinciding with the appearance of the Emiran around 50 ka B.P. There is debate, however, whether its root(s) were autochthonous or exogenous. Emiran core technology employs a distinct method of bidirectional Levallois point production that is regionally traceable. While some of these technological features appear in the preceding Levantine Mousterian, they are far more prevalent within the Afro-Arabian Nubian Technocomplex. The Emiran exhibits affinities with the late Nubian (~85 – 70 ka B.P.) and Taramsan (~70 – 50 ka B.P.) of Middle Egypt, as well as the Classic Dhofar Nubian (~100 ka B.P.) and the Mudayyan industries of southern Oman. Elongation is consistent with the Dhofar Nubian and Levantine Mousterian, but not the Nilotic assemblages. Cresting appears in the late Nubian of Egypt and Dhofar, but not within the derived Taramsan or Mudayyan. Thus, the Emiran combines indigenous Levantine Mousterian elements with the Afro-Arabian Nubian Technocomplex. A hybridization model is parsimonious with the archaeogenetic proposition for interbreeding between humans and Neanderthals in the Near East between 100 and 50 ka B.P.

Rosen, Arlene (University of Texas at Austin)

[17] Geoarchaeology at the Edge: Measuring the Pulse of Process and Human Agency at the Interface of Landscape and Site in Neolithic through Iron Age China

In much of his research, Karl Butzer has inspired generations of geoarchaeologists to investigate the
human and social aspects of landscapes and societies. This endeavor is often physically manifested at
an archaeological site by sediments representing the halo of human activity just beyond the residential
area, where the “site proper” meets the edge of a managed landscape. It is here that landscape
processes driven by natural hydrological changes in an alluvial system dovetail with socially-motivated
processes. The social processes link landscape management or mismanagement to consequent stability
or degradation. Human agency is also detectable at these interfaces in the form of agricultural fields,
terraces, canals, and other distinct features at the periphery of the residential portion of the site at any
given time. Investigations of these “geoarchaeological ecotones” in Henan and Shandong Provinces in
China illustrate small-scale agency in the management or ‘taming’ of floodplains during the Neolithic
Period by the physical evidence of sediments linking paddy fields and farm houses. ‘Processes’ in the
form of cycles of landscape stability and disruption are also evident at these interfaces by periods of soil
formation versus episodes of uncontrolled flooding, induced by Han imperial land-use policies.

[17] Basic Instabilities? Climate and Culture in the Negev over the Long Term
Settlement systems in the Negev, Israel’s southern desert, over the past 15,000 years show cycles of
demographic rise and decline. Examined at different geographic scales, these demographic cycles
should be tied to patterns of geographic expansions and contractions deriving from different culture-
geographic sources. Together this variability suggests instabilities in basic social geographic structures,
undoubtedly to be tied at some fundamental level to the difficulties of subsistence in the environmentally
harsh desert. On the other hand, if the general pattern of cycles or fluctuations should be tied to some
essential property of desert adaptation, the specific incidents of expansion and florescence, followed by
contraction and decline, should be tied to historically particularistic episodes of climatic fluctuation,
cumulative technological change, internal social and demographic trends, and to input for societies on the
desert periphery, ostensibly the sedentary core zones. Finally, if these patterns are examined at larger
chronological and geographical scales, clear patterns of long term continuity emerge, belying the idea of
essential cultural instability.

[173] A Study of Social Rank and Resource Control Using Ichthyofaunal Remains from the Cathlapotle
Plankhouse Village Site
Social inequality and inherited rank are trademarks of the social organization of Northwest Coast Native
Peoples, and faunal remains are one potential path for examining this. My thesis work tests the
relationship between prestige differentials and subsistence patterns through the analysis of fish remains
from the Cathlapotle plankhouse village site (45CL1) on the Lower Columbia River. Using models from
optimal foraging theory to develop a ranking system for fish taxa based primarily on size, I examine the
degree to which social rank designations of households and house compartments are reflected in the
spatial distribution of ichthyofaunal remains relative to their taxonomic rankings. Analyses based on NISP
comparing compartments within a household show a higher proportion of salmon relative to lower-ranked
minnows/suckers in the compartment where elite village members likely lived, indicating possible post-
harvesting control of preferred resources by the elite. Comparing between households, more of the large
chinook salmon species relative to smaller non-chinook salmon are found in the more highly-ranked
household, indicating possible household-level ownership of fish harvesting sites or runs. My research
informs on the nature of resource control in the region as well as the efficacy of drawing conclusions
about social rank through faunal remains.

Rosenswig, Robert (University at Albany)

[118] Tributary Mode of Production and Justifying Ideologies
In his definition of the tributary mode of production, Eric Wolf proposes that those societies that extract
economic surplus through political means generate religious models of the cosmos where supernatural
beings provide a metaphor of tribute relations in the human world. As Wolf (2001:349) puts it, “…public
power is thus transformed into a problem of private morality.” This is a classic Marxist assertion that
religion creates false consciousness and motivates people to act against their material interests. Rather than simply assuming this proposition is correct, anthropological data can quantitatively evaluate it. Using a broad sample of societies, this paper evaluates whether mode of production determines beliefs about the structure of the cosmos. Do all societies where tribute is extracted by political means have similar justifying ideologies? Conversely, do societies where surplus extraction occurs through kin relations lack such justifying ideologies? My goal is to evaluate Wolf’s intuitively logical proposition with anthropological data. The implications of this evaluation are at the heart of a materialist understanding of causation by empirically evaluating whether material conditions generate consistent ideational beliefs.

Rospigliosi-Campos, Cristina (Southern Illinois University) [150] Sociopolitical Organization during the Late Intermediate Period in the Peruvian North Coast: Excavations at the site of Luya

This paper presents results from excavations carried out at the Late Intermediate Period site of Luya located in the Middle Lambayeque Valley. I will discuss data obtained from excavations and preliminary pottery analysis of Late Sican period monumental architecture, public spaces and metal production areas. Following models based on the ethnohistorical record rather than neo-evolutionary approaches, I examine the regional political organization as revolving around local centers or curacazgos, rather than managed by a macro regional state apparatus. I will address how the Sican people at the site of Luya managed economically and politically this part of the valley through public meeting spaces, metalworking activities, and agricultural production areas. Finally, I will briefly describe the interaction of previous technologies from the Middle Horizon (i.e. arsenical copper production), with ancient political practices such as the consumption of alcohol (chicha) in public meetings.

Rossen, Jack (Ithaca College) [342] Revisiting Myers Farm: The 2013 Excavations at a 15th Century Cayuga Farmstead, Central New York

The second field season at the Myers Farm site, east of Cayuga Lake in central New York, was conducted during the summer of 2013. The new excavations add to the previous understanding of the site as a 15th century farmstead where communal feasting occurred. Newly revealed are a cookhouse and elaborate storage pit system. The new excavations also emphasize the presence and material culture of children. In general, this small site encourages new ways of analyzing site structure and artifact assemblages like ceramics and limestone hoe blades.

Rossi, Franco (Boston University) [3] All About Xanab: Understanding Ancient Maya footwear

Footwear is an oft-overlooked detail of Maya dress, though like any bodily adornment, it followed its own particular set of conventions, which in turn governed manufacture, use and decoration. In ancient Maya art, vivid glimpses of elaborate sandals and other footwear can be seen on various stela monuments, ceramic vessels and murals depicting high-ranking lords in costume. Many other artistic works display the simpler side of footwear, showing more basic sandals in a variety of contexts. This paper utilizes these historical representations and artistic depictions as a primary means of exploring ancient Maya footwear—first identifying various “fashionable” trends cross-regionally and through time and then fleshing out the particulars regarding manufacture and use through archaeological examples, ethnohistory and ethnohistory. As the guardians of individuals’ primary means of movement, footwear was as vital piece of adornment in antiquity as it is today, and would have been a key medium for signaling aspects of individual identity and status. By understanding how items of dress like footwear, were created, used, and represented by ancient societies, archaeologists can not only explore technologies of production and consumption, but can also access subtle windows into social hierarchies, gender dynamics and politics of display in ancient societies.

[79]  **The Life and Death of Urraca Man**
During the summer of 1970, ancient human skeletal remains were discovered in an open-air rock enclosure high on Urraca Mesa, Colfax County, NM. The individual, now known as “Urraca Man,” was found with over 18,000 glass trade beads, metal tools, knives, copper bracelets, and butchered animal bones. The artifacts place the date of death somewhere between about 1860 and 1890. Early researchers speculated that he was a “mountain man” or trapper of European descent. More than a decade later, another anthropologist concluded that the remains were those of a Native American, now making them subject to NAGPRA (25 U.S.C. 3001 et seq. 1990). However, a complete reanalysis of the skeleton using modern methods, including platymeric index and CT cross-sections of the subtrochanteric area of the femur, together with a complete reanalysis of the artifacts and re-excavation of the location of the original find, suggests that he was in fact a trader on the Taos/Rayado Trail, likely of Caucasian descent with some African admixture. Moreover, our analysis details the first assessment of the cause and manner of death. Pending ancient DNA (aDNA) results, provided DNA can be extracted and amplified, will support or refute our ancestral assessment.

[168]  **The Women of San Jose de las Huertas, NM**
Accounts of colonial interactions in the American southwest privilege the colonized (Native Americans) and the colonizers (Spanish). However, almost immediately after the Entrada a new and highly significant third group was formed. Called variously mestizo(a), hispano(a), or classified in a number of castas, this group has not received the archaeological attention it merits in the region. The roles of women are also particularly neglected in colonial situations. We will specifically consider the women who lived at San Jose de las Huertas from around 1765-1826, and their children who subsequently founded Placitas, NM. Our information comes from excavation, historical research and oral history with some descendants; a rich trove of data comes from the WPA records created in the 1930's. We will focus on women's roles, their important activities centering the community and in the network of kin relations. Although not highly visible through the archaeological research, the oral accounts demonstrate their agency and power.

Rouse, Lynne (Washington University in St. Louis)

The discovery of the Bactria-Margiana Archaeological Complex (BMAC) in modern Turkmenistan and Afghanistan revitalized study of ancient interaction networks in greater Central Asia, placing the BMAC alongside other 3rd millennium ‘core’ areas in Mesopotamia and the Indus Valley, as agrarian urban heartlands whose power was drawn from resources and populations exploited in a 'peripheral' hinterland. However, new archaeological research highlights the activities of 'peripheral' nomadic populations in their own right, revealing that the interpretation of prehistoric Central Asia as characterized by dependent core-
periphery relationships sets up fundamentally flawed notions of power, reflected in the conceptual dichotomy between urban farming communities and mobile pastoralist groups. I review the growing body of archaeological evidence, including my own work in the Murghab delta, that can contribute to a revamped conceptualization of prehistoric relationships in the region. By envisioning a socially-based network of urban/nomadic nodes and flowing connections between them, we neutralize the deterministic view of power as rooted in economic relationships and introduce multiple layers of interaction, thereby doing more justice to the reality of both prehistory and the modern era, where all types and sizes of communities actively negotiate their social, political, and economic worlds through their engagements with one another.

Sanya Paulia's Rock Shelter: Prehistoric Contexts in coastal Guinea

While investigating around a 19th century slave trading post called Sanya Paulia, on the Rio Pongo, Guinea, local villagers told Kelly about a cave where people could hide if attacked. We didn't really know what to expect but the cave's soil deposition looked extensive and some historic ceramic fragments were visible on the surface. Hypothesizing that we might recover a collection of prehistoric ceramics that could be compared to 19th century local ceramics we established a test pit in this cave. This small rock shelter turned out to be much more than just a safe retreat for the villagers. Between the 14th and the 17th of March 2013, Kelly and Rousseau, helped by Guinean students, supervised the excavation of the 1 sq. m. test pit near the main entrance, where available digging space was best and where multiple prehistoric activities usually take place. Each arbitrary 10cm layer was richer than the last and we dug until it was no longer safe, approximately at a 1.8m depth. The results: thousands of lithic flakes and ceramics sherds in an occupation that might span more than 5000 years of history. This paper presents the preliminary results of Sanya Paulia's rock shelter excavation.

Rowe, Robert [166]  
The Geomorphology of the Four Sites area along the South Platte in Northern Colorado

The excavation and installation of a natural gas liquids pipeline allowed for opportunistic investigations to be conducted along the middle South Platte River near the Cache le Poudre delta to better define the geomorphic contexts of several Paleoindian sites (Frazier, Jurgens, Klein, Powars and further to the west, Dent) within the local area. These Paleoindian sites are located on the Kersey terrace, alluvium of which was deposited during Clovis occupation and stabilized by 10,000 B.P. The alluvium of this area is the results of flooding from both rivers creating a complex soil column. Post-Clovis sites post-date aggradation and steam down-cutting may have started as early as 10,500 B.P. Subsequent floodplain development shaped by both rivers and down-cutting later formed the Kuner terrace (3000 B.P.) and the Hardin terrace (1000 B.P.), both of which limit the locations of the earlier sites. Aeolian sands began accumulating in the region by 10,000 B.P. but most are probably late Holocene deposits and are indicative of a drier post-Pleistocene climate. Understanding of the late-Quaternary geomorphic history of this portion of the South Platte could aid future archaeological research and complement geomorphic research in other reaches of the South Platte.

Rowland, Joanne and Judith Bunbury (University of Cambridge) [17]  
Environmental Change in the Western Nile Delta from the Middle Paleolithic into the Neolithic: New Considerations Regarding the Mobile and Settled Communities in the Vicinity of Merimde Beni Salama

By the Neolithic, Merimde Beni Salama became part of the shore of a lake or lagoon. The mud deposits suggest that this was relatively extensive with at least 4 km² body of water, 4 m deep, that would have been well-suited to species such as the hippopotamus, for which Merimde is well-known. The settlement at the site seems to be located around the fan and flanking terrace sediments from the mouth of the Wadi
Gamal. With time, the fresh water would have dried up as the distributary system of the Delta became more strongly channelized and the climate became drier. However, the next main event that we have evidence for is an influx of sand (that is bleached of its desert pellicle) which may indicate that it was deposited into water. Following this, the action moved away from Merimde as we see now. Earlier Pleistocene finds are probably part of earlier cycles of this type of which there were at least six during the Pleistocene. From a better understanding of environmental change in this area, we can explore further the climate cycles in the region and how this affected the habitation patterns in the Mid to Late Pleistocene.

Investigating Long-Term Patterns of Fish Use in the Interior Plateau through the Ancient DNA Analysis of Fishbone

EeRb-144 is a large Early to Late Holocene archaeological site located in the Interior Plateau of southcentral British Columbia, Canada. A multi-year excavation of the site conducted as part of the Secwepemc Cultural Education Society-Simon Fraser University Archaeological Field School has produced a large amount of heavily fragmented fishbone. This fragmentation has generally precluded the classification of these remains through traditional zooarchaeological analysis to a taxonomic level lower than class. However, ancient DNA (aDNA) analysis can be used to assign species-level identifications to even extremely fragmented archaeological fishbone. In this study, aDNA analysis was employed to assign species identifications to a sample of Middle and Late Holocene fishbone from EeRb-144. These identifications were used to investigate temporal trends in the taxonomic composition of the site’s fisheries, and the fishing strategies used by its inhabitants. The character of these trends provides insights into long-term patterns of fish use in the Interior Plateau, and the nature of large-scale cultural processes in the region.

The Hieroglyphic Platform at Kabah

In front of the western façade of the Codz Pop at Kabah is a low, four-sided platform, once faced with at least two levels of stones carved with hieroglyphs. Today, only about half of the blocks remain on the monument; the rest lie scattered in the rubble. The current placement of the stones on the platform dates to the early 1950s, when Raúl Pavón Abreu reset the loose blocks with the hope that it would preserve them for future scholars. However, due to the condition of the stones, and the disorder of the inscription, decipherment of the hieroglyphic monument has been challenging. Research in 2013 resulted in a complete catalog of the hieroglyphic blocks, enabling a new understanding of these previously enigmatic inscriptions. In this paper, we present our findings, placing the hieroglyphic monument at Kabah within the larger corpus of Terminal Classic inscriptions from the Northern Lowlands and offering a new interpretation and reconstruction of the structure.

Archaeologies of Native Production and Marketing in 19th Century New England

Research on Native Americans’ acquisition of European goods has challenged ideas about the naïveté of their consumption choices as well as assertions that they perceived the foreigners’ things as technologically superior and readily substituted them for their own. By drawing attention to Native people’s agency in the selection and redefinition of material goods in diverse Indigenous contexts, these studies have transformed the ways archaeologists think about Indigenous consumption during early colonial encounters and in later colonialism. Consequently, few today would interpret Native families’ increasing reliance on store-bought, manufactured goods in recent centuries merely as evidence of cultural loss and assimilation, or would ignore the interpretive possibilities presented by assemblages of incongruous things to confront stereotypical expectations about Native Americans’ impoverishment, incompetence with modern technology, and gullibility as consumers. However, Native peoples were not just consumers of “non-Native” goods: they also made things for European-American consumption. This paper explores Native Americans’ production and marketing of baskets and natural medicines in urban New England during the 19th century. Reversing the interpretive angle to Indigenous peoples’ tactics as
producers and sellers further contributes to destabilizing pervasive ideologies that situate them mostly at the receiving and often dependency end of consumer culture.

[282] Lonesome Landscapes as Post-Contact Refugia

The society-altering effects of Euro-American contact on Native peoples throughout North America are well documented. Native people endured devastating population losses through disease and disruption of their traditional economies. Many Native people were incorporated into new economies and their material culture reflects the incorporation of new tools and foods. There are also some documented instances of resistance and rejection of the imposed new systems in which Native people fled to remote areas. Here we present two southern California examples of likely Native refuge sites in what were then considered remote areas by the incoming Euro-American groups. The sites, located on San Clemente Island, and in the Coso Mountains of the Mojave Desert, were occupied by groups with highly distinct economies and cultures and subjected to different historical stresses by the incoming groups. Common to the two examples, however, were locations that were not desirable to Euro-American settlers until relatively late in time. Using the Ideal Free Distribution as a theoretical framework, this paper argues that the very things that made these locations “Lonesome Landscapes” allowed Native cultures to continue in traditional ways until the 1850s on the Channel Islands and the 1870s in the Coso Mountains.

[343] Swamp Tools: Late Paleocene to Early Eocene Tropical Forests and Archaeology

During the Late Paleocene and Early Eocene a tropic/sub-tropic forest in east-central Colorado was enveloped by volcanic eruptions causing the creation of the Paleosol-Dawson Arkose formation. The primary area of this geological formation is located in Elbert County, between Colorado Springs and the small town of Kiowa. Large stands of tropical wood became silicified as a result of the deposition of volcanic ejecta creating distinctly colored petrified wood. Due to erosion and uplifts of the formation, large areas of surface exposed petrified wood became an easily accessible lithic source for native populations to exploit. The distinct color of the petrified wood allows archaeologists to trace tools made with that material to the Paleosol – Dawson Arkose formation. Phase 1 surveys in support of the excavation and installation of a natural gas pipeline across the study area allowed a unique opportunity for archaeologists to map through the deposition of the silicified wood to determine the extent and type of exploitation that was taking place within the native populations.

The chronology of the different styles of open-air rock art of Iberian Peninsula has been an open question since the discovery of Levantine art 100 years ago. This naturalistic style is the cornerstone of the complex relations among the rest of styles of the area: Paleolithic, Schematic and Macroschematic. Levantine art has some formal traits of Paleolithic style, and at the same time it has a complex stratigraphic seriation with Macroschematic and Schematic styles, both of them considered of Neolithic age or younger. Our research group began a scientific dating program ten years ago trying to get the first scientific dates of Levantine art. A multidisciplinary research team has contributed since then with several AMS ¹⁴C datings of oxalate crusts in six shelters from two distinct geographical areas. M.W. Rowe and his collaborators have been in charge of processing these samples by plasma-chemical extraction or acid treatment. The results suggest that at least a part of Levantine art was of pre-Neolithic age. Some of these results suggest that oxalate datings may produce reliable maximum and minimum ages for a group of pictographs under certain conditions. We expect to go further in this research line in the near future.

Runggaldier, Astrid (University of Texas at Austin)
[61] From Village to City: Contributions from San Bartolo’s Architecture, Art, and Writing in Revealing the Development of Preclassic Lowland Maya Culture.

Over the last few decades we have come to understand the Preclassic Maya Lowlands as a complex landscape, replete not only with agricultural villages, but also with towns and cities of different sizes. At the relatively small settlement of San Bartolo in northeastern Guatemala, architecture, art, and writing coexist in cohesive programs of formal design at the scale of individual structures and up to entire groups, demonstrating that specialized architectural configurations have a deep history of development evident in codified arrangements by the start of the Late Preclassic period. E-Groups, ballcourts, triadic arrangements, and palace complexes have established forms and symbolic values, connecting small and large sites in patterns of shared meaning. In this presentation we explore the Maya center of San Bartolo from the perspective of built environments and visual programs of painting and writing that created the appropriate urban space for the early traditions of Maya kingship and statehood.

Rush, Haley (Cox|McLain Environmental Consulting)

The Rowe Valley Site (41WM437): A Study of Toyah Period Subsistence Strategies in Central Texas

In the latter half of the Late Prehistoric Period in Central Texas, the Toyah period, a drastic cultural change occurred, marked by the appearance of a unique artifact assemblage often recovered in association with bison remains. Bison remains are virtually unknown in the period that precedes the Toyah period. The change in material culture has often been linked to the reappearance of bison and the development of the Toyah people adjusting their economic strategy to one that specialized on hunting bison. Deposits at the Rowe Valley site, a large Toyah campsite, contained extensive faunal remains which included deer, antelope, and bison. The presence of a considerable amount of faunal materials along with the sites' location in the core of the Toyah area, made Rowe Valley an ideal site for study. Analyses of the archaeological materials combined with experimental studies demonstrated that the economic focus at the Rowe Valley site was not on bison. It is clear that a drastic change in material culture did occur at this time however, this study suggests the economic strategies utilized were still generalized and adapted to unique local environments.

Radiocarbon Ages of Oxtotitlan Murals

Rock art murals at Oxtotitlán Cave in southern Mexico contain iconographic elements similar to Olmec monuments on the Gulf Coast. To investigate whether the rock art could be associated with the Olmec, we conducted a study of the pigments with the goal of establishing the age of the artifacts. Paint pigments in the site were first analyzed using a portable X-ray florescence which showed that most of the black pigments did not contain manganese, and thus likely carbon-based. Samples from two murals were collected, one from a large, bi-chrome shield motif and another from the polychromatic C-1 mural that has elements similar to other Olmec artifacts. Adjacent samples were also collected to provide information on the substrate and rock coatings. Chemical studies in the laboratory demonstrated that the black pigments were made from soot, and that the natural rock coatings are primarily calcium oxalate. We extracted the carbon in the pigment using a low-temperature oxygen plasma, and the resulting CO2 was sent for radiocarbon analysis. The oxalate coatings on the paint and off-paint samples were treated using dilute phosphoric acid to remove carbonates and also sent for C-14 dating.

Russell, Will (Arizona State University)

Diachronic, Nonlocal Influence at the Mimbres Site of Galaz

Archaeological evidence from the Mimbres area has generated inferences of homogeneity in material assemblages and inter-societal interaction. New data and recent research suggest a more diverse social landscape wherein Mimbres households and villages negotiated differential access to nonlocal communities. This analysis employs data from the multi-component Mimbres site of Galaz to examine the ways in which nonlocal interaction impacted Mimbres cultural trajectories at an intra-site scale. Did households have equal access to nonlocal goods? Did the intensity, manner, or constituents of connectivity change over time? To approach these questions, I synthesize evidence of Mimbres
interaction with Hohokam and Mesoamerican sources during the Late Pithouse, Classic, and post-Classic occupations at Galaz Ruin. Evidence includes nonlocal artifacts, features, practices, and iconography. Analyses compare the relative frequencies of such indices, over time and at different scales, ultimately presenting new evidence for asymmetrical and persistent access to nonlocal communities.

[52] Preliminary Underwater Exploration of Cenote Sac Uayum, Mayapán, Mexico

In the summer of 2013, with support from The Waitt Foundation for Exploration and The National Geographic Society, the Mayapán Periphery Project concluded its first season of exploration at Cenote Sac Uayum, a sacred, water-bearing sinkhole located at the Postclassic Maya political capital of Mayapán, Yucatan, Mexico (1100-1450 A.D.). The study yielded significant new insights into the cenote that many modern inhabitants consider “alive” and believe to be guarded by a large serpent that some say has plumage and the head of a horse. The feature has drawn the attention of researchers working at the site since the first archaeological work began based on its conspicuous and apparently intentional exclusion from the city by the large city wall surrounding the bulk of the settlement. The modern belief in a feathered serpent guardian only heightened that interest. Before dive work began, we conducted a Jeets’ Lu’um or “calming of the earth” ceremony which provided new data on modern Maya cave ritual and beliefs. Our team focused on detailed underwater mapping and photography of the cenote and its contents. We recorded 15 human crania, a large number of other bones and ceramics attesting to the use of the site as a burial location.

Rutecki, Dawn (Indiana University Bloomington)

This paper discusses the alterations, innovations, and changing foci of feminist inspired education and scholarship in archaeology. Legacies of previous feminist scholars continue to influence how we incorporate these new directions into our research, but also provide the means to expand how we think and teach archaeology. Diversification of agendas has led to new approaches for integrating feminist thought into the discipline. Community building and engagement, stemming from feminist and post-colonial scholarship, extends not only to the communities with which we work, but the students and colleagues that we encounter on a daily basis. These fluid communities form sites of possibility and transformation concerning what feminist archaeologies means, how they are enacted, and the future effects they can have on the discipline.

[38] Maintaining Community in a Sociopolitical Frontier: Recent Data from Cerro Colorado de Huacho, Huaura Valley, Peru

The Chimu empire began expanding along the north and central coast of Peru during the latter part of the Late Intermediate Period (ca. A.D. 1300-1476). Preexisting social and political boundaries were reinforced and often redrawn after the Chimu successfully conquered regions. The fluctuation of these sociopolitical frontiers profoundly affected the development and maintenance of unconquered regions by creating an unstable social, political, and economic environment. The Huaura Valley, located on the southern edge of the Norte Chico geographical region, represents one example of a sociopolitical frontier in the LIP. This research is designed to address the ways in which an individual community developed and maintained itself within a frontier context at the site of Cerro Colorado de Huacho. The site consists of three large architectural features dating to the LIP and Late Horizon including a fortification, public administrative complex, and Inka tampu. Excavations in 2012 focused on the fortified walls as well as test units in areas identified as domestic zones. Site development, social interaction, and culture contact will be examined in light of new data drawn from recent excavations and artifact analysis of materials from Cerro Colorado de Huacho.

A recent theoretical emphasis on the New Animism raises important issues for the study of pictographs and petroglyphs in the interpretation of the archaeological record. This paper explores how the animistic ontologies of the Numic-speaking communities of the Great Basin and Colorado Plateau are expressed vis-à-vis ritual activities within cultural landscapes that include manifestations of volcanism such as hot springs, craters, and caves. Comparing three archaeological sites including Toquima Cave, Darrough’s Hot Spring, and Tinemaha that are inscribed with rock images and used for Ghost Dancing activities during the late nineteenth century, repeating and unique uses of animated ritual landscapes are investigated.

[32] Architecture, Alignments, and Astronomy at the Harris Site in the Mimbres Valley

Many Pueblo sites in the American Southwest have demonstrated architectural alignments to astronomical phenomena. However, few pithouse sites, in particular in the Mimbres-Mogollon area, have been investigated for similar alignments. This study attempts to change that trend by researching architectural alignments and solar events at the well-known Harris Site in the upper Mimbres Valley. The study found that many entryways were oriented to the sunrise and sunset positions on key astronomical dates (i.e., solstices and equinoxes). There were even important solar alignments between communal structures on site. These results show that the Mimbres-Mogollon were keen observers of solar movements during the Late Pithouse Period and incorporated some of their observations into their architecture.

Ryan, Philippa (The British Museum)

[22] Perspectives on Near Eastern Neolithic Basketry from the Phytolith Traces at Çatalhöyük (Central Anatolia)

Basketry found at Çatalhöyük East (7,400–6,000 cal B.C.) is mostly preserved as silica-skeleton (phytolith) traces, and more occasionally as impressions in clay or through partial charring. This paper discusses their preservation, appropriate sampling methods and some of the types of plants exploited for basketry. Traces of coiled basketry, matting and cordage are often found in well-defined domestic and burial contexts. Some of the potential uses of these objects, such as for storage, will also be considered. There is also possible evidence for changes in the use of some categories of basketry over time. The numerous silica skeleton remains at Çatalhöyük highlight the importance of basketry as an artifactual class during the Near Eastern Neolithic.

[333] Kiva Production and Community Integration in the Northern Southwest

This paper analyzes the vernacular architecture of ancestral Pueblo kivas dating from the Pueblo II (A.D. 900-1150) and Pueblo III (A.D. 1150-1300) periods in the northern, middle, and southern San Juan regions in the northern Southwest in order to shed light on communities of practice and their social, temporal, and spatial production practices. This research specifically examines kivas—or round rooms used for public and domestic activities—to address how architecture emphasized the ways in which features were actively mediated by communities of practice and how their semiotic signatures can illuminate how architecture was developed to create and maintain social structure, social identity, and community integration.

[225] Photogrammetry as a Documentation Tool during fieldwork: Research and Result Presentation Phase

Photogrammetry has been one of the rapidly advancing documentation methods in archaeology. While studies have been made on the topic of the method’s cost efficiency and precision, I believe that there are yet undiscovered (or unpublished) methods for using it in archaeology. With using the possibility of creating
orthophotos from a 3D model, we can greatly reduce the distortion from the camera lenses. At the same
time we can make photos, that otherwise would require us to be 25 feet above the excavation trench. With
using these features photogrammetry becomes a powerful, quick and therefore cost efficient method for
capturing the texture and elevation of different surfaces. I would like to share our experience, namely with
Agisoft PhotoScan, in the University of Tartu and show how photogrammetry could be used during
fieldwork, research and result presentation phases. Fieldwork use would be shown with the example of the
Haapsalu gallows hill, research phase with the smithy site of Kaku on the island of Saaremaa and
presentation phase with two Egyptian mummies.

[251] Design and Style in Sacred Bundle Baskets from the Great Mortuary at Spiro
Important components of the Great Mortuary cosmogram recently identified by James Brown at the late
prehistoric Spiro mound site in eastern Oklahoma are sacred bundles composed of double-woven lidded
baskets and associated sacra. Here we examine the interplay of basket-weave choices that contributed
to the structural integrity of the baskets and “artistic” treatments made at the discretion of the weaver. We
also compare basketry motifs and artistic motifs rendered on other media found in the Great Mortuary,
including engraved shell and carved stone. These comparisons yield exciting new information on stylistic
variation among the “communities of practice” who contributed items for inclusion within the cosmogram.

[42] Reconstructing a Great House: A Case Study from West-Central New Mexico
Despite decades of focused research on Chacoan-style great houses, the impetus for their construction
and the extent to which their users directly interacted across the Four Corners region remains poorly
understood. A key research question is whether these structures represent an articulated system with the
center of interaction at Chaco Canyon or whether they represent a regional conceptualization of
community-based activities enacted on more localized scales. The range of variability evidenced by
Chacoan-style great houses suggests that local social context played an important role in how each
community constructed and utilized these structures, and also influenced the degree of interaction
between great house communities.

Recent research in the southern Cibola region of west-central New Mexico has been directed at better
understanding the role of Chacoan-style great houses within their local and broader social contexts. We
present a case study of the Largo Gap great house in which we compare its construction and patterns of
use to Pueblo II great houses across the Southwest, examine the nature of its use within the context of its
associated support community, and evaluate its patterns of interaction with both local and more distant
great houses.

[302] Betwixt and Between: The Ceramics of Ka'Kabish, Belize
The site of Ka'Kabish is located in an area between the Booth's and La Lucha Escarpments of
Northwestern Belize, which defines the Peten ecological boundary, and the coastal environment of
Belize. The site was initially occupied in the Middle Formative and had its heyday in the Late Formative and Early Classic periods. Current research suggests that the site center did not have significant occupation after the Early Classic, although the surrounding area was heavily occupied during the Terminal Classic through the Middle Postclassic. Ka'Kabish's ceramic affiliations, particularly in relation to other sites in Northern Belize and the Northeastern Peten, will be a primary focus. Because of the scarcity of later occupation, Ka'Kabish provides an opportunity to delve into some of the ceramic identification issues in the Formative period as well as an exploration of Early Classic ceramics.

Hair Today, Gone Tomorrow: The Degradation and Conservation of Archaeological Hair Fibers

This presentation describes the degradation and conservation of archaeological hair fibers. After researching the structure of hair fibers, and their physical and chemical attributes, research focused the degradation of hair fibers in different environments. Hair fibers were left in underwater, open air, burial, and arid environments. The samples were monitored for degree of degradation and brittleness before and after environmental exposure. The degradation of the fibers in different environmental conditions showed that burial in acidic sandy clay is the most detrimental to hair fibers, while hair fibers from arid, dry environments are brittle, but well preserved aesthetically. The hair fiber types used are four commonly found in archaeological context: coarse wool, fine wool, mohair, and human hair. After weathering, conservation using polymer passivation was tested on the degraded hair fibers. When the treatment proved to be a viable conservation method, the technique was then applied to two artifacts. The two artifacts used were a Victorian era watch fob made from human hair and hair fibers mixed with tar from the excavation of Kittern in Bulgaria. The polymer passivation treatments were shown to be viable treatment methods with positive results for all of the fibers tested, including the two artifacts.

Technological Behavior in the Middle Stone Age of the Gademotta Fm., Ethiopia: Insights from the Levallois Method

The Middle Stone Age (MSA) has attracted extensive research attention over the past few decades because of its association with complex behaviors. Notwithstanding, the debate on the timing and pace of behavioral changes, a common generalization is that MSA technologies become more sophisticated through time. Previous models have emphasized the stepwise increase in specific technologies. In the present study, we use MSA sites from multiple securely-dated contexts in the Gademotta Formation of the Main Ethiopian Rift to show that trajectories of technological evolution are complex. Specifically, we examine Levallois reduction method in six MSA sites representing three different periods: >279 ka, 260-185 ka, and ~105 ka. By holding contextual factors (such as access to and quality of raw materials) constant, we examine diachronic variability within the MSA. Results indicate that diagnostic characteristics of the Levallois method are shared across these sites spanning much of the MSA. However, certain temporal trends that pertain to the major focus of the Levallois method and its end products are also observed. The almost ubiquitous nature of the Levallois method in the MSA is used here as a convenient attribute in the investigation of hominin behavior.

He Koko Pu'upu'u? (A Chiefly Gourd Net?) An Analysis of Recovered Fiber Arts from Makauwahi Cave, Kaua'i

In the summer of 2011, several well preserved pieces of a rare Hawaiian carrying net were recovered from Makauwahi cave during an archaeological field school hosted by the University of Hawai'i and the National Tropical Botanical Gardens on the south end of Kaua'i. The complexity and decorative aspects of the type of knot used for this net's construction suggest that this item may be a k6k6 pu'upu'u, or chiefly gourd net. Because of the perishable nature of common components used in customary cordage manufacture, Pacific Island rope work generally has poor representation in the archaeological record making this uncommon find appealing for detailed investigation. This paper addresses what can be learned...
from examining and comparing the physical characteristics of this rare example of Polynesian netting and proposes further research that may show promise regarding Pacific Island fiber arts. A focus on the stylistic analyses of rope construction and knot work as it is demonstrated between and within Pacific Island communities is emphasized in this study.

[60] Hilltop Settlement in the Late Prehispanic Andes: A Global Review of the Pukara Phenomenon through Ethnohistory and Geomatics

It is well known and widely documented through the Andes that settlement patterns shifted to higher altitudes during the last centuries preceding the Spanish conquest. While various reasons (climate change, territorial balkanization and sociopolitical conflict, etc.) have been proposed to explain this apparently global phenomenon in the Andes, a systematic cross-regional study on the topic does not exist so far. The Andean concept of "pukara"—generically a hilltop fortified settlement—was first documented in ethnohistorical sources and described and explained through European eyes. Thus, a critical review of ethnohistorical literature is necessary to counteract potential medieval misconceptions about the way of living uphill in the Andes. Second, hilltop settlements are very numerous in the late prehispanic Andes, and in fact a great deal of diversity exists in the architectural and locational patterns of settlements called "pukara" in the archaeological literature. For this reason we present here a comparative study of late prehispanic settlement patterns related to the pukara phenomenon across various study zones in the central Andes. Comparative analysis based on satellite imagery and 3D terrain modelling of architectural and locational characteristics offer new insights to apprehend the pukara phenomenon at an Andean scale.

[10] Luminescence Dating and Chronological Reconstructions in the Arizona Strip and Adjacent Areas in the American Southwest

The Arizona Strip and adjacent areas have been the focus of archaeological studies to understand the prehistoric trading pattern due to their widely distributed olivine-tempered ceramics. To understand the changes in the production and distribution patterns of olivine-tempered ceramics, accurate reconstructions of ceramic and site chronologies are necessary in addition to the source study. For this purpose, optically stimulated luminescence (OSL) dating was conducted on 109 sherds from Mt. Trumbull, which is the source of the olivine and the lowland Virgin area, which is one of the distant areas where the olivine-tempered pots were found. This paper addresses three basic questions: (1) how these OSL dates correspond to the 14C dates available in the study area, (2) how the distributions of these OSL dates establish the site chronology in the Mt. Trumbull and lowland Virgin areas, and (3) how these OSL dates develop a ceramic chronology in these areas. This paper also examines how the trading patterns between Mt. Trumbull and the lowland Virgin area has changed over time by combining the LA-ICP-MS chemical compositional data of 1,069 sherds with these OSL dates.

Saldana, Melanie (California State University Los Angeles)

In 1999 Dr. James Brady came to California State University, Los Angeles as the first Mesoamerican archaeologist in the university's more than fifty year history. With no infrastructure for teaching Mesoamerican archaeology, Jim created foundational courses, established a dedicated laboratory, and expanded artifact and library collections making Mesoamerican Studies a vibrant focus in the Anthropology Department. Beginning in 2001, he took students from this predominately minority campus into the field with full financial support. Under Jim's mentorship, these students have parlayed their research experiences into an impressive list of awards and honors that made Anthropology one of the elite departments on campus. With few exceptions students participating in Jim’s field projects have presented the results of their research in the annual SAA cave sessions becoming a vital part of our field’s participation in this conference. Moreover, his students have found success beyond the Cal State
system by going on to Ph.D. programs, so that the Cal State L.A. program has become an important source of new cave archaeologists. This paper takes a historic look at Jim’s contributions to Mesoamerican cave archaeology through his tenure at Cal State L.A.

Saldaña, Julio (Pontificia Universidad Catolica del Peru), Luis Jaime Castillo (Pontificia Universidad Catolica del Peru), Fernando Zvietcovich (Pontificia Universidad Catolica del Peru) and Benjamin Castañeda (Pontificia Universidad Catolica del Peru)
Several tools and equipments have been available for years in order to acquire three-dimensional models from archaeological artifacts and sites. Previous to this study, we have worked on a 3D method for the acquisition and processing that improves the accuracy and precision of the recording procedure of ceramic fragments when compared with the traditional one of drawing. Also, we have proposed a 3D reconstruction technique of complete vessels based on the mentioned fragments which has been applied to a database of profile contours taken from 3D models of paicas, large ceramic containers for liquids from the Moche of the North Coast of Peru. Preliminary results provide good and accurate estimations. Now we plan on evaluating the advantages of the application of this method in terms of how it improves the archaeological record, essential for interpretation and conservation as well as how we can now calculate the volume of vessels in order to determine the scale of ritual practices that involve the consumption of ritual drinking at the site of San Jose de More, an elite and ceremonial site in Jequetepeque Valley, Peru.

Salgado, Silvia (Universidad de Costa Rica)
[197] Interaction between the Atlantic Highlands and Lowlands in the Case of Two Chiefly Villages
Since the 1970s, there has been a constant interest in the study of complex societies in Costa Rican archaeology, which are commonly typified as chiefdoms. This interest is not only theoretical but mainly historical due to the fact that ethnohistorical studies indicate that this type of sociopolitical organization was present across the Atlantic and other regions of Costa Rica. Archaeologists, therefore, see an opportunity to explore not only prehispanic sociopolitical processes but their continuity in the Colonial and even Republican periods, as shown also by ethnographic studies of indigenous populations in the 20th century. Herein we compare and discuss the developments of two chiefly villages, the Alto del Cardal situated at a 2600 masl on the slopes of the Irazú volcano, and the Nuevo Corinto settlement situated at a 230 masl. Both villages were connected by a pathway through which people, ideas and goods interacted. We discuss aspects of chronology, territoriality and the dynamics of interaction, to contrast the archaeological interpretation from those provided by ethnohistorians on the characteristics of the chiefdoms of the area.

Sallum, Marianne (SALLUM, M.) and Plácido Cali (CALI, P.)
[323] Tupi Pre-Colonial and Colonial Pottery: Changes and Continuity (Southern Coast of Sao Paulo State/Brazil)
The current work presents a study of the pottery technology related to the indigenous Tupi people that
lived in Peruíbe – at the southern coast of São Paulo State - Brazil, during two historical occupation periods: before and concurrent with a Franciscan hamlet in the 18th century. The archaeological site occupies about four hectares and it is situated between the sea and the Abarebebê ruins – an archaeological site where the São João Batista hamlet’s old church is found. This work is focused on the Tupi’s occupation path in this region, based on the premise that there is an historic continuity between the pre-colonial Tupi peoples and those mentioned in the historic documentation. Three campfires and around 4,000 pottery fragments were dug, including many mountable pieces of pot. The ornaments include engobe painted decorations as well as ungulate, corrugated and incised decorations, associated with remnants of vegetal macro-remains, bones, animal skulls and coal. In other areas, shell concentrations were found, associated to stoneware, porcelain, glass, pipes and indigenous pottery with colonial features. Thus, there are evidences in the material culture that certify a long term history and a confluence between Tupi people and the Europeans that arrived there.

Salomon Salazar, Maria Teresa

[60] Entre los cerros del Epiclásico: el valle de Puebla-Tlaxcala

En la literatura mesoamericana se habla frecuentemente que muchos de los sitios Epiclásico (600-900 d.C.) se pueden considerar defensivos debido a una tendencia a ubicarse en elevaciones naturales que estratégicamente los convierten en fortalezas. La definición de sitios del Epiclásico en el valle de Puebla-Tlaxcala ha seguido estos modelos de interpretación, asumiendo que para este periodo el descontrol económico que causa la caída de Teotihuacán provoca el surgimiento de asentamientos defensivos. En esta ponencia pretendo evaluar la evidencia que hay al respecto, y se señalan las fortalezas y/o debilidades del argumento. En esta ocasión se compararán la ubicación y las características consideradas defensivas de sitios como Cacaxtla, Cerro Zacapotlac, Manzanilla, entre otros, con el fin de entender mucho mejor el muy polémico periodo Epiclásico en esta región.

[236] Taphonomic and Zooarchaeological Analysis of the Early Epipaleolithic Site of Tor at-Tareeq (WHS-1065), Jordan

We present the results of faunal and taphonomic analyses from the 2012 field season at the Early Epipaleolithic site of WHS 1065 (Tor at-Tareeq) in west-central Jordan. By combining the fauna with data from earlier field seasons, we are able to provide a more comprehensive view of human adaptations during the Last Glacial Maximum (25,000-18,000 cal. B.P.) at this site. We examine the subsistence adaptations of the site’s occupants using the prey choice model, and prey mortality and carcass exploitation measures. The study reveals a low intensity subsistence strategy based primarily on hunting high-ranked game like gazelle and wild ass. Several taphonomic indices reveal significantly better preservation conditions in the deeper sediments. A layer of impermeable breccia that caps the deeper sediments, protected the ecofacts from exposure to climatic and seasonal elements that damaged the bones closer to the ground surface.

Sampeck, Kathryn (Illinois State University)

[72] An Archaeology of Indigo: Modernity and the Landscape of Obrajes in the Izalcos Region of Western El Salvador

Mesoamericans used the Central American dye plant xiquilite (indigo) during the Late Postclassic period to dye cloth, and Spaniards were enamored of its relatively permanent, vibrant blue color. Colonial production of indigo is first documented in the sixteenth century in the Izalcos region of today’s western El Salvador. Trade of indigo blossomed in the seventeenth century, with indigo cakes being used as a form of payment. Indigo was a part of the colonial economy well into the nineteenth century. The process of making indigo into dye profoundly changed from its pre-Columbian roots to the colonial period, ushering in many of the processes and social relations of modernity. Each step of indigo processing involved new technologies, including water wheels, canal and drainage systems, and large vats. This mechanized
process depended on laborers, often slaves, working in a factory setting. Archaeological examples of the built environment of indigo obrajes illustrate the conditions of labor during the genesis of modernity.

**Spatial and Hierarchical Relations among Political Centers in the Intermediate Lands of South Pacific Costa Rica**

The intermediate lands in the South Pacific of Costa Rica have been the subject of several archaeological projects by the University of Costa Rica. Nucleated villages have been documented to have had different levels of complexity in architectural design and cultural elements that characterize them. A multiscalar approach has been used in order to understand and interpret the internal relationships of some of these villages, as well as to explore local and regional linkages that might have existed, particularly during the period ranging from A.D. 800 to 1500. Theoretical and methodological limitations that could have affected the results are mentioned and discussed, as well as multiple research questions that can be explored in the future to gain access to other levels of explanation about hierarchical relationships between the main villages in the South Pacific.

**Late Pleistocene Landscapes and the Clovis Occupation of Sonora, Mexico after Ten Years of Systematic Investigations**

In the last 10 years our knowledge of the Late Pleistocene occupation of Sonora, Mexico has increased exponentially, mostly due to systematic investigations carried out in the region with support of the Argonaut Archaeological Research Found (AARF). A total of 114 Clovis points have been recorded in Sonora and twelve sites have been registered in the Plains of Sonora Landscape physiographic province; geoarcheological investigations have been carried out in five of these sites. Encampments kill sites, hunting localities, and lithic quarry sites represent the Sonoran Clovis record. Probably the most important site that we have found is the El Fin del Mundo site that has been under study for the last six years. The site consists of at least 25 localities including; a buried stratified feature where Clovis peoples hunted Pleistocene elephants (gomphotheres), several camp areas, and two lithic quarries. Four Clovis points were found in situ at the gomphothere feature; in 2012 charcoal fragments were found associated to one flake and bone fragments at the western end of the gomphothere feature. A radiocarbon date was obtained from one of the charcoal fragments with a 14C-age B.P.: 11560 ± 140 (cal B.P.: 13454 ± 170).

**Beyond Pretty Pictures: The Benefits of Virtual Heritage**

Archaeology is tedious. The discipline demands exactitude, copious documentation, rigorous analyses, and prompt dissemination to peers. That rarely happens. Archaeology is also about understanding past cultures, and since the past happened in 3D, in color, and as a continuous set of actions, it would seem to make sense to study the remains of the past with similar parameters, rather than as the disconnected, 2D, black and white images that are still too common in the discipline's final excavation reports, teaching materials, and Websites. Plans, sections, and elevation drawings (the fundamental “sacred triad” of architectural documentation for millennia) have been central to archaeological visualization since the inception of the profession well over 200 years ago, and they persist despite the availability of more appropriate and more accurate alternative image types. After nearly two decades, the interactive computer
models of virtual heritage practitioners are now being used more widely than ever for hypothesis testing, fieldwork documentation, classroom exercises, museum displays, and augmented-reality-based tourism. This paper explores the benefits of virtual heritage for archaeologists and provides a glimpse into the future of archaeological visualizations.

[140] Back to Basics... Where Was the Pottery Made? A Petrographic Analysis of Chalchihuites and Aztatlán Pottery from Durango and Sinaloa, Mexico
Decorated pottery has been the key in all archaeological investigations in the state of Durango. By categorizing it, several hypotheses have been made. To begin it has been said that Chalchihuites evidence is result of diffusion and interaction with Alta Vista inhabitants, but it has also been said that Aztatlan materials in Durango are consequence of the trade routes across the Sierra. Leaving behind those interpretations, by reassessing the archaeological data from an interdisciplinary point of view, we go back to basics and start with questions such as: Where was the pottery made? What are the social implications of their provenance? In this poster we present the methodology and results of applying a petrographic method to Chalchihuites and Aztatlán vessels, starting with a microscopic view, and going to its implications related to interaction of human agents

[302] Preliminary Results of the Gallon Jug-Laguna Seca Survey and Reconnaissance in Northwestern Belize
This presentation discusses the findings of the Belize Estates Archaeological Survey Team (BEAST), an operation of the Chan Chich Archaeological Project, during the summer 2013 field season. Survey took place on cut seismic survey lines crossing the Gallon Jug and Laguna Seca property in northwestern Belize. During the 2013 season, BEAST investigated over 48 kilometers of linear survey, and conducted targeted opportunistic survey and reconnaissance, including revisits of previously recorded sites. Although the lines available for survey had been established for seismic studies, without prior consideration to archaeological potential, specific lines were chosen due to their coverage of areas spanning several different vegetation types and topographic settings. Four new named sites were recorded along with over 140 individual structures, containing several areas of dense settlement with as-of-yet unidentified site core associations.

[85] Negotiated Subjugation: The Incorporation of Chincha into the Inca Empire
Maritime adaptations are as old as the human presence on the Peruvian coast—at least 13,000 years. Complexity began to emerge in this region before 4000 BP in a context in which marine resources played an important, if debated, role. The influence of coastal opportunities in hierarchical social organization did not end with the first complex societies, however, but continued through the entire prehistoric period up to and including the conquest of the coast by the Inca in the late fifteenth and early sixteenth centuries A.D. This paper discusses the archaeological and ethnohistoric data on the Inca incorporation of the south coast kingdom of Chincha. The Chincha apparently used their expertise in seafaring to negotiate a privileged role in the Empire, providing access to the sacred Spondylus shell and perhaps other high-status goods from as-yet unconquered coastal Ecuador by acting as raft-borne merchant/agents for the highland Inca landlubbers.

[159] **New Perspectives on Human-Landscape Relations in Non-Agrarian Communities**

A growing body of evidence from around the world shows that hunter-gatherer communities often invest far more energy into transforming their surroundings than traditionally thought. A particularly intriguing aspect of research is the investigation into “monumentalized” landscapes produced by non-agrarian peoples and how these findings challenge orthodox understandings of monuments as being intrinsically related to ownership and inequality. Drawing from published accounts, as well as recent fieldwork conducted on two large-scale sites in coastal Georgia, this paper suggests a return to the original meaning of monument as related to memory and history rather than power and grandeur. This interpretive shift suggests that monument creation is a particular method of inscribing events, both experienced and imagined, into the landscape and as such creates historically-charged places marked as separate and different than their surroundings. The social impact of creating and engaging with such monuments on hunter-gatherer communities is an important archaeological question that this paper will begin to address. Additionally, the traditional methodological focus on labor-hours and energy-expenditure associated with monument creation loses its applicability when monuments are interpreted as history inscription rather than materialized power. As such, new methods are required; a topic broached, although not concluded, within this paper.

[321] **New Technological Studies of Pueblo I Glaze Paint**

Although widely employed in prehistoric Eurasia, lead glazes were produced in only two small regions of the Americas prior to European contact, both in the Southwest. The first independent invention of glaze paints was in the Upper San Juan River drainage of southwestern Colorado during the early Pueblo I period (ca. 700-850 C.E.). Despite extensive research on the later Pueblo IV glaze paints of New Mexico (ca. 1275-1600/1700 C.E.), there have been no technological analyses of the Pueblo I glaze paints. This research project presents the first analysis and technological reconstruction of the Pueblo I glaze paints using x-ray fluorescence (XRF) spectroscopy, backscattered electron (BSE) imaging and wavelength dispersive spectroscopy (WDS). Our sample was selected from sherds with good provenience and chronological data excavated during the Animas-La Plata (ALP) Project. Previous research from the ALP Project suggests that during the Pueblo I period, people with different cultural histories came together in the first attempts at village formation in the Upper San Juan. Our technological reconstruction has the potential to provide important information regarding relationships and interactions of potters and their role in negotiating differences among the various groups who were living in the Upper San Juan at that time.

[214] **Scaffolds and Links, or How to Trace Staged-Learning through a Productive Chain**

While learning has recently become a prominent area of research within archaeology, tracing its history and character through objects has proven difficult. This is particularly true when learning is considered a staged event in which novice engagement with objects is intermittent rather than sustained. Learning to make pottery is often staged in that novices assist in particular aspects of the productive chain while more experienced individuals perform other tasks. As such, individual vessels often go through multiple hands, making assignment as “novice-wares” problematic. This paper offers a way forward through the application of a constellation of techniques; each of which provides information on a discrete link in the production sequence and assess the level of skill reflected in particular attributes. By applying these methods to two pottery assemblages from neighboring contemporaneous sites, the shortcomings and potential feasibility of these techniques are highlighted and new research directions are offered.

State Formation in Eastern Peripheral Region of Japan

Sasaki, Ken-ichi (Meiji University)

In the process of state formation in Japan, highly-characteristic keyhole-shaped tumuli or burial mounds were distributed all over Japan. Many of them shared the “standard of mound construction,” and the same construction plan was adopted to keyhole-shaped tumuli in different regions away from one another. It seems that the highest-ranking chief in the central polity distributed the construction plan to local elites. Looking into detail, however, some local polities acted independently from the central polity. This was particularly the case in eastern peripheral regions of Japan. For example, the construction of keyhole-shaped tumuli reached its peak in the sixth century in eastern Japan when the construction of keyhole-shaped tumuli declined in the central polity. In northeastern Japan a part of a keyhole-shaped tumulus was destroyed in the construction process of a circular tumulus in the sixth century, although a keyhole-shaped tumulus is considered as the symbol of the highest social status in the central polity, much higher than those buried in circular tumuli. These lines of evidence indicate that, while local elites also built keyhole-shaped tumuli, there was some room for the local elites to act independently from the central polity. Japan was not fully unified in the sixth century.

Landscape Learning in Cosmic Proportions

About 3,500 years ago across the lower Southeast U.S., a community of practice coalesced around the shared experience of sea-level rise. Their forebears, over scores of generations, experienced transgressive seas that flooded ancestral homeland and pushed communities landward repeatedly. With its low gradient and sandy composition, the Gulf coastal setting of this shared history was especially vulnerable to shoreline erosion and inundation. Did living through centuries of constant change in such an environment make communities of practice capable of projecting futures far beyond the next generation? If so, the spatial, as well as temporal, scale of learning was virtually cosmic, transcendent of individual or small-scale community experience to encompass a multigenerational, translocal learning process. A variety of archaeological evidence from sites across the Gulf coast of the Southeast is marshaled to argue that futures planning was embedded in the material arrangement of both built and “natural” places, all with reference to celestial events, notably the solstices. With settlements, cemeteries, monuments, and caches positioned with reference to the movement of the sun, time was mapped onto space to anticipate, and thus cope with change—a lesson modern people might ponder in their own challenges with climate change.

Vessel Size and Feasting in three Chacoan Great House Communities

Measuring rim sherds and identifying the size of vessels is one method used to identify feasting. Larger than normal vessels may indicate larger scale food preparation for larger groups of people than the normal household. Chacoan Great Houses are thought to be used as gathering places for local communities, and to be the locus of ritual and feasting activities. If true, Great House ceramic assemblages should differ from those of smaller household residences, especially in terms of size. Here, we report vessel size data from the smaller residences and Great Houses in the southern Cibolan communities of Cox Ranch Pueblo, Cerro Pomo and Largo Gap to assess ceramic evidence for feasting.

[295] More Than Meets the Eye: Examining the Spectral Response of Sugar Cane to Subsurface Features

While the application of remotely-sensed imaging to archaeology has grown dramatically in recent years, much of this work continues to rely on the qualitative identification of archaeological features as geometric anomalies in vegetated or arid regions. There are fewer analyses of the spectral responses of archaeological features, although recent studies in Near Eastern, Mediterranean, and Mesoamerican regions are important contributions. Here we describe spectral behavior of densely vegetated sugarcane fields in response to anthrosols and archaeological features in the Chicama Valley, Peru, from the Moche-Chimu periods (ca. AD 300–1400). The extensive sugarcane cultivation in Chicama affords the opportunity to analyze the expression of water- and salinity stress in relatively homogenous vegetation landcover, and at various life stages from emergence to senescence. Using extant archaeological survey data, we relate this to anthropogenic features, including soil alterations from prehispanic agricultural and settlement systems. Previously undocumented sites are also recorded. In addition to the obvious implications for archaeological analysis, these results help interpret the legacy-effects of prehispanic land use on modern agricultural potential, and can be used to plan mitigation efforts.

[31] Cuello’s Preclassic Burials: A Unique Life History of a People as Written in Their Bones

When we joined Norman Hammond’s Cuello project in Belize in 1976, we had no inkling that we were about to encounter a veritable treasure trove of Preclassic skeletal remains. Poor skeletal preservation in the tropics may encourage an archaeologist to ignore skeletal remains or dispose of them hastily with only a cursory look. In the case of Cuello, the sample is unusually complete and well documented because Norman chose to extract every bit of information from every source (including skeletons) in every portion of the site, and he carefully excavated to bedrock. Although often eroded and fragmentary, careful excavation, reconstruction, and osteobiographic analysis of this unusually large and well documented collection of Preclassic skeletal remains yielded surprisingly good information about the people of Cuello. Population composition, disease, trauma, nutritional indicators, cranial shaping, dental decoration, activity markers, cultural behaviors - pictures gradually emerged of individuals, and later of the population as a whole.

Saunders, Michael (Tulane University)  

After completing research mapping of present-day Maya sacred site layout and documenting correlations to ideas of sacred geography known for ancient Maya, my work has concentrated on the (often crucial) ecological associations of modern sacred geography. This research uncovered not only important links to ecologically sensitive or critical areas (especially those related to water issues), but to archaeological locations as well (themselves often situated in key environmental settings). Although present sacred locations are not necessarily – and indeed are often not – archaeological sites, evidence gathered on the northern rim of Lake Atitlán, Guatemala, increasingly points to a relationship between contemporary sacred sites and archaeological remains. Such links offer insight for both archaeologists studying pre-Hispanic Maya as well as anthropologists examining modern Maya populations. Importantly, as well, recognition of the relationship between archaeological remains, local ecology, and current sacred site layout and utilization provides evidence of long-term environmental management. Demonstrating such lasting management through combining archaeological and ethnographic data can have important implications for current environmental issues. Moreover, such links indicate the novel possibility of locating archaeological remains through investigations of contemporary sacred geography.

Sauza, Maximiliano, Lourdes Budar (Universidad Veracruzana) and Sara Ladrón de Guevara
El glifo conocido como "Ojo de Reptil" es un elemento iconográfico mayormente utilizado en la plástica mesoamericana durante el periodo Clásico. El Ojo de Reptil es reconocido por muchos investigadores como de gran trascendencia debido a su asociación con Teotihuacan y ha sido interpretado la mayoría de las veces como un glifo de carácter calendárico. Sin embargo, pese a su importancia, no ha sido investigado de forma profunda. El nivel de abstracción que presenta su diseño, así como la variedad de estilos y contextos en los que fue representado, denotan que su importancia no sólo radica en la asociación al centro rector del altiplano, sino a su contenido y carga simbólica en su representación misma. En este trabajo se expondrán algunos elementos que sugieren que el Ojo de Reptil más que un glifo calendárico, es un símbolo multivalente mesoamericano.

**Savory, Samantha**

**[172] Brook Farm: A Ceramic Analysis of a Short Lived Utopia**

This research focuses on the ceramics that were used by the members of the Brook Farm site. Brook Farm was a community in Massachusetts established in 1841 and ending in 1847. Brook Farm was an experiment in social reconstruction started by reuniting man and nature in a communal and agricultural community inspired by Transcendentalism. In 1844 Brook Farm officially adopted a new social reform theory, Fourierism, which incorporated the industrialization occurring in the New England at the time. The beliefs of the Brook Farm members and their communal living situation would have required a certain ceramic assemblage in order to accommodate the volume of people living in the community. Studying the ceramics from Brook Farm will determine if the members chose certain ceramics based on their needs and beliefs while living in the community. A comparison of the Brook Farm assemblage and other New England site assemblages will determine if the Brook Farm assemblage is unique. The comparison of Brook Farm with assemblages from sites in New England will also determine if the members were bringing their own ceramics or if Brook Farm was supplying the ceramics.

**[251] Centered Pipes and Swirling Pots: The Cult of First Man and Ritual Iconography in the Mississippian Southeast**

A series of pipes known as Bowl-Giver pipes exhibit a male figure looking up while holding a clay pot with strap or loop handles. This ceramic pot also functions as the bowl of the pipe. These pipes represent a commonly understood visualization of the culture-hero known as First Man. Bowl-Giver pipes appear to be affiliated with very specific ritual practices and cult manifestations associated with First Man, the use of tobacco, and ceramic pots. Although stylistically dynamic, these pipes suggest they were linked to widespread and commonly understood rituals and an ideology concerned with centering.

**Sayers, Daniel**

**[118] Modes of Production and the Resuscitation of Historical Praxis**

Praxis has (re)emerged as a powerful concept through which we can explore past human action without necessarily engaging the very ambiguous, and tired, notions of agency and identity. Political-economic conceptualizations of praxis compel foci on thoughtful and critical individual and group actions of the past, while also being highly congruent with Mode of Production frameworks. Such frameworks, long relegated to passé status it would seem, press historical researchers to think dialectically, while also inspiring attention to political-economic conditions at multiple scales. In this paper, I discuss how my Modes of Production-focused research in the Great Dismal Swamp of Virginia and North Carolina has sought to recover evidence of the historical social praxis of swamp-dwelling people, such as African American Maroons, between ca. 1600 and 1860. Additionally, I discuss how the contemporary resuscitation of past systems of praxis can impact our future.

Sayle, Kerry [89] see Hamilton, W.
To understand the impact of self-induced climate change on present-day society, there must be interpretive distance between what is climatically produced on a landscape or biosphere as opposed to what is a consequence of human modifications to that landscape. The ancient Maya constitute one of the best-studied, deep-time bellwethers for tropical society. Maya societies existed without our technological emphasis, but were institutionally and structurally organized as nested hierarchical states in parallel to modern world culture. Approaching human-nature couplings that existed between the Maya and their environment permits a transparent assessment of significant aspects of our current convoluted and nonlinear complexity, but reduced to a scale manageable for holistic assessment of long-term environmental and social change. The charge of IHOPE-Maya is to: (i) examine regional climatic influence on the environment independently of human action or reaction; (ii) draw upon our work in identifying the controlled temporal development of the engineered landscape; and, (iii) assess the actual impact of climate on social change. Through this exercise, it is possible to identify past processes that have meaning for modern societies as we face geometrically increasing rates of environmental change.

[122] Cave Art Acoustics: The Role of Sound in the Painted Caves of Northern Spain
The Upper Paleolithic painted caves of southwest France and northern Spain provide some of the earliest evidence for human symbolic behaviors, but the potential role of sound in the activities that were undertaken in these enclosed spaces has not hitherto been adequately explored. Some 25 years ago it was suggested that the placement of the images was related to the particular resonance acoustic of those locations. That relationship has been explored by our recent acoustical study of five painted caves in Asturias and Cantabria. The results of this new work are compared with the earlier claims, and set against the background of anthropological evidence for the importance of sound in the ritual practices and belief systems of traditional societies. It is concluded that while at a general level sound probably played a part in the activities associated with the images in Upper Paleolithic painted caves, a direct connection between acoustics and images remains difficult to establish. The special acoustics of the caves are nonetheless one of the most striking features of these underground systems and the sensory experience that they provide.

[331] Local Knowledge, Local Voices: Many Ways for Decolonizing Archaeological Practice in Amazonia
Amazonian peoples have long experience with colonization, both during the colonial period, in which most of the region was under the Portuguese rule, and in the last century, when the region has suffered the imposition of large infrastructural projects that are executed without taking into account local histories and rights. The state policy for the archaeological heritage protection implies the imposition of authoritarian laws without regard for local sociocultural diversity and autonomy. Very often, unfortunately, the western science practiced by archaeologists in the field does not acknowledge cultural diversity and the rights of culturally diverse people. Drawing from field experience, this paper proposes that archaeological research in Amazonia demands both an anthropological perspective, and field projects opened to different voices and knowledge. It is also discussed ways to establish less asymmetrical relations with local people, recognizing their right to sociocultural diversity, while producing an archaeological knowledge more committed to local realities.

Schaich, Martin [154]  Combined Airborne and Terrestrial 3D Scanning and Photogrammetry Surveys with 3D Database Support for Archaeology and Cultural Heritage

The German surveying company ArcTron 3D specializes in the digital documentation of archaeological objects and historical monuments. Over the past few years, some large-scale 3D documentations with combined scanning technologies have been realized on archaeological sites in South America (Bolivia, Peru). This talk will present a technical evaluation of these projects and their advance for archaeological research. One of the core processing tools is ArcTron's own 3D information system aSPECT3D. It can combine data from various sources (total stations, GPS, 3D scanners and photogrammetry) and is especially suited for use in cultural heritage. The intuitive user surface makes it easy to handle for everyone, who wants to work with 3D data. A whole new 3D photogrammetry application (ImageScan Module) presents a low-cost alternative for creating 3D models and is very suited for archaeological objects. The presented projects used a combination of airborne photogrammetry and terrestrial laser scanning. aSPECT 3D produces photorealistic 3D models ready for scientific analysis. The main tool for this is the integrated PostgreSQL database, which systematically helps to manage 3D geometry data. 3D models can be segmented, structured and annotated—e.g., in form of damage mapping. aSPECT 3D takes archaeological data analysis into the third dimension.

Scharf, Elizabeth (University of North Dakota) and David Rhode (Desert Research Institute) [23]  Packing for the Trip: Plant Remains from High Elevation Sites in the Great Basin

High-altitude (> 3000 m) environments in the Great Basin were used almost exclusively during the late Holocene. Early use of alpine areas is primarily associated with hunting camps and hunting-related facilities, such as drive lines and hunting blinds. More recent use involved the construction of multiple residential dwellings (‘villages’) at particular locales, implying much greater investment and duration in occupation. This paper presents information on botanical remains from Midway (in the White Mountains of California) and Alta Toquima (in the Toquima Range of Nevada), both sites containing multiple occupation components in the late Holocene spanning the period of increased residential occupation. Differences in plant use between early and late occupations of these sites reveal how these late Holocene occupations were utilized and subsidized, in part, by subsistence resources from lower elevations. We use these data as a basis to consider more broadly the role of plant foods in the subsistence economies of high elevation occupation of high elevation areas within and outside the Great Basin.

Scharlotta, Ian [163]  When a “Midden” is not a midden: The “Encinitas Midden,” San Diego County, California

CA-SDI-17402, located on Moonlight Beach in Encinitas, California, was originally recorded as a meter-thick midden, consisting of dark soils with sparse artifacts, dubbed the “Encinitas Midden.” Recent development uncovered a series of ten thermal features dating to the Archaic period, further supporting the cultural origin of the deposit. Regional analysis of contemporary sites indicates that Moonlight Beach was likely a stopover point for travelers along the San Diego coast. During excavation, charcoal appeared
lacking, leading to a detailed analysis of the soils. A combination of Loss-on-ignition, FTIR, pXRF, GC-MS and microscopic analysis of charcoal remains from soils taken inside and outside of features, as well as from sterile strata produced ambiguous results. No evidence could be found to support a cultural anthrosol, black mat or similar organic formation, or contamination from petroleum derivatives. Evidence for movement of the outflowing creek explains impacts to specific features, but provides no insight into the deposit at large. Surrounding bluffs do not present a logical source for dark sediments, yet a sizeable stratum of dark soil is present, in association with hearth features, that is clearly not a midden.

[161] Non-Center Domestication in Southeast Mesoamerica

The El Gigante rock shelter holds some of the oldest stratified archaeological deposits described for Southeast Mesoamerica. The cultural adaptations of early Archaic people represented at the site highlight the diversity and dynamism of later indigenous groups such as the Lenca. This paper describes changes in the avocado (Persea americana) remains found at the site. The macrobotanical preservation of pits and rinds was excellent throughout occupational horizons. The identified specimens span the very early Archaic through the Formative periods. Metrics (length, diameter/radius) and statistics (size indices, coefficient of variation, ANOVA analysis) are presented from which the directed selection for larger fruit is inferred. The interpretations highlight connections that form and operate within an unfolding process of agricultural intensification and landscape transformation. These changes are met in part through the adoption and manipulation of both annual and perennial species. The rate and direction of selection evident in the avocado assemblage is compared with the highland Mexican collection from Tehuacan.

Scheiber, Laura (Indiana University)

[159] Archaeology as Mediator of Place, Heritage, and Tourism in the American West

The image of the contemporary American West incorporates numerous pervasive myths related to the near and distant past. The dominant narrative recalls the American Frontier, Indian Wars, Wild West shows, and a cast of colorful characters. Meanwhile past Native presence, as well as its impact on the surrounding landscape, is often disregarded in part based on successful wilderness policies in national parks and forests, which claim pristine environments untouched by humans. The tourism industry capitalizes on a history of the West that remains thus manipulated and constructed. In this paper, I discuss the way that the archaeology of modest campsites and hunting features can help bridge gaps in Western heritage that exist in part because of the Yellowstone tourist industry. According to the Crow (indigenous residents), time is not as relevant as place in history, and historical events are tied to place much more than they are to time. Archaeological data can be incorporated with oral histories about nearby prominent natural features to reveal a more in-depth engagement with the process of place-making in the past and present. Likewise, archaeology can also engage with the history of the recent past by emphasizing linkages between places and people in historically-manipulated contexts.

[90] Rock Art as a Mortuary Practice in North Patagonia

In Patagonia, some archaeological publications noted certain recurrence between the presence of human burials and rock art in Patagonia. Rizzo (2012) demonstrated that this association was not statistically significant. However, in those sites where there was rock art and human burials, the hypothesis that certain rock art, or at least certain motifs, could be associated with the presence of burials, remains untested. Here, we propose a method to test this hypothesis. For this work we will focus on a specific area of Northern Patagonia (Argentina) and a specific rock art style (known as Fret Style, Menghin 1957) which was dated from 700 AP onwards. Departing from archaeological literature and sites studied from first hand, we will build a database that records all sites where there is an association between rock art and burials and all motifs (pictographs, as this is the predominant rock expression) present in each site. The hypothesis rejection will allow considering that rock art was performed independently of the burials. But if it is corroborated certain rock art motifs could be indicating the
presence of burials, and then those motifs could be considered as a mortuary practice, accompanying the burial.

Schele, Elaine (Austin Community College)
[319] A Tale of Two Dates: A New Look at the Controversy over the Age of the Bones of K'inich Janab' Pakal I
In 1952, when Alberto Ruz discovered the magnificent tomb of K'inich Janaab’ Pakal I, the most important Classic Maya king of Palenque, Mexico, he also discovered Calendar Round (CR) dates on the edge of the tomb’s sarcophagus lid. No Long Count dates were present to anchor them in history. According to Ruz’s physical anthropologists, the king’s remains within the tomb were those of a 40 to 50 year old. In every subsequent report Ruz wrote where he referred to the dates on the lid, Ruz anchored the first inscribed date which was 8 Ahau 13 Pop at AD 603. That date was the presumed birthday of the occupant of the tomb. However, 16 years later in a 1973 publication, Ruz re-anchored this CR date to A.D. 665. 1973 was also the year that Linda Schele and Peter Mathews presented a information on the kings of Palenque using newly deciphered hieroglyphic readings at the First Palenque Roundtable where they contended that the age of Pakal was 80. Others joined in the debate and thus began a scholarly argument that lasted for several decades. This paper is a new look at the events and the personalities associated with this controversy.

Schepartz, Lynne
[303] Feasting Men, Suffering Women: Social Roles, Diet and Health at Mycenaean Pylos
The sociopolitical structure of Late Bronze Age (ca. 1675-1050 B.C.) Mycenaean is generally understood from their written records (primarily accounts of economic transactions and preparations for feasts and rituals), monumental art, and mortuary practices. In this study, bioarchaeological data from high status tholos tombs and chamber tombs at Pylos were used in conjunction with stable isotope analysis to investigate observed differences in dental health. Frequencies of caries and antemortem tooth loss (AMTL) differ significantly by sex and social stratum. Individuals from tholos tombs have significantly fewer caries and AMTL, and women have more dental pathology than men of the same rank. Greater access to animal protein from feasting activities, predicted for the highest status individuals, is hypothesized to be the reason for these differences. This was verified by carbon and nitrogen isotope studies, where individuals from the tholos tombs are clearly associated with greater access to protein and the males from those contexts have the most elevated protein values. Social rank and gender, not access to wealth, seem to have been the key factors underlying patterns of dental health among the Mycenaeans.

[192] The Boat Woman’s Dress: Net Imagery and Meaning in Moche Iconography
Fishing imagery, like all imagery of the Moche of north coastal Peru (0-800 C.E.), is laden with associated meanings that evoke the relationship between the world of humans and the supernatural world. The Boat Woman, also called the Moon Goddess, is a figure that originates in the Southern Moche but moves to prominence in the female-centered iconography of San José de Moro in the North. She wears a dress that mimics the design of nets used in Moche depictions of fishing and deer hunting. This paper explores the visual relationships among the netted dress, fishing nets, and deer nets, and postulates what these relationships might mean in the expression of gender roles, site identity, and the political relationship between Northern and Southern Moche.

[128] Border-Building and Territory-Taking in the Usumacinta River Basin
Over a decade of research on issues of borders, boundaries, and frontiers in the Middle Usumacinta River region of Chiapas, Mexico and Petén, Guatemala has shown that neighboring Classic period Maya dynasties developed distinct strategies for occupying frontiers, establishing borders and expanding the limits of royal authority. These differences reflect the particularities of history, geography, and political strategy among each kingdom. Contemporary lords had very different relationships with the territories they sought to control, the people they claimed to govern, and the networks of production and exchange that flowed in the shadow of their courts.

[253] The Passion for Mosaics in Lapidary Art at Tak'alik Ab'aj, 2000 Years Ago and Today: The Mosaic Project at Tak'alik Ab'aj

Excavations at Tak'alik Ab'aj have revealed a considerable collection of Preclassic and Early Classic lapidary art based on the technique of mosaic assemblages. Among which the most notorious are five iron pyrite mosaic reflectors and seven jadeite mosaic ceremonial miniature heads. Four reflectors and one miniature head was found in situ, as part of the royal funerary apparel of Late Preclassic Burial No. 1 located in the depth of ceremonial platform Structure 7. Hundreds of jadeite mosaics of six disassembled miniature ceremonial heads and one iron pyrite mosaic reflector, as part of Early Classic massive offerings deposited in front a staircase of Structure 86 in the West Group of Tak'alik Ab'aj and at the central sacred vertical axis at Structure 6, provide valuable primary and secondary contextual and chronological data. This, carefully documented, represent the platform for the current Mosaic Project at Tak'alik Ab'aj, which study, re-assemblage and conservation, offers information and insights about ancient design concepts, production and assemblage techniques, and signal regional Mesoamerican lapidary traditions through time.

[328] The Archaeology of Science

In their reconstruction of technologies, archaeologists have been studying the scientific knowledge produced by prehistoric peoples. This paper argues that archaeologists may also study the science of early modern and modern societies, seeking to formulate generalizations. This can be achieved by a focus on the people-artifact interactions occurring during activities that lead, for example, to discovery claims. Examples of such generalizations are provided that shed light on discovery processes.

[343] Buffalo Jumping in the Black Hills

Native Americans from the Northern Great Plains have a long history of using communal, mass kill techniques to obtain occasional surpluses. Techniques such as jumping or trapping animals in pounds were especially effective at yielding tremendous quantities of food and other products from animals, like the Plains Buffalo (Bison bison), that were otherwise difficult to kill using more individualistic hunting strategies. Buffalo jumping, where prehistoric hunters stampeded herds of buffalo over a cliff edge is typically depicted as an indiscriminant, non-selective hunting technique. A recent archaeological project at the Sanson Site in Wind Cave National Park investigated the remains of a late prehistoric multi-component site that includes a buffalo jump feature. Multiple lines of evidence indicate many different kinds of activity took place at the site over a very long time. In particular, large-scale constructed landscape features show that early hunters were highly knowledgeable about buffalo behavior and were able to guide animals to the jump. This knowledge and use of the landscape may have allowed the selection and targeting of specific subsets of the local bison population.

Schillinger, Kerstin (University of Kent), Alex Mesoudi (Durham University) and Stephen J. Lycett (University of Kent)

Cultural evolutionary approaches stress that only few social learning processes have the capacity for high-fidelity copying that reduces variation generated by unintentional copying errors. However, the question of whether contrasting social learning mechanisms generate distinct patterns of variation in the archaeological record is largely unexplored. Here, we designed an experiment using 60 participants who aimed to copy the shape of 3D "target handaxe form" from a standardized foam block. In an 'imitation condition', 30 participants were shown manufacturing techniques employed in the production of the target form and the target itself. Conversely, in an "emulation condition," 30 participants were shown only the end-state (target) form. Copying error rate in the "imitation" condition was significantly reduced compared to the "emulation" condition. Moreover, the imitation condition matched the demonstrated behaviors with significantly higher copying fidelity than the alternative condition. Our results illustrate that imitation may be imperative for the long-term perpetuation of visibly distinct archaeological traditions. We propose that the bias to faithfully copy goal-directed manufacturing techniques meets the capacity to reduce the potential for
cultural mutation in reductive manufacturing traditions. Our findings provide evidence that imitation may be required to explain the prolonged continuity of shape standardization in the Acheulean.

Schipani, Alexandra (Eastern New Mexico University)

[13] The Use of the Scapula to Determine Biological Sex
The scapula contains sexually dimorphic aspects and should thus be useful for creating a technique for determining biological sex. Forensic anthropology is a relatively new field of study with numerous under-tested methods including techniques for determining biological sex. In forensic anthropology, the pelvis and the skull are considered the most reliable areas of the human body to determine sex, however; these areas are often damaged in the archaeological record. Another method suggested by researchers, such as using the scapula, may aid in identifying the biological sex if it is further studied and documented. Researchers have proposed using the scapula to determine the sex of an individual; however, a concrete method has yet to be established and tested. This study will serve to develop concrete evidence that the scapula can be an adequate method for determining biological sex. Through the development of a guide that contains specific instructions for using the scapula to determine sex, it is hoped that the scapula will be deemed an adequate bone in the human body when compared against collections of human remains with known biological sex.

Schlanger, Sarah (Bureau of Land Management) and Signa Larralde (Bureau of Land Management)

[151] All the Gold on the Map: Public Land, Public Good, Public Trust
The Bureau of Land Management likes to describe the public lands as “all the gold on the map.” Here we use examples from personal and professional history to describe the arc of cultural resource management as it has played out in the Bureau of Land Management and on the public lands over the past four decades. Our review includes “FLPMA babies” (the cultural resource specialists hired by the Bureau to meet its obligation to comply with NHPA, ARPA, and the Federal Land Policy and Management Act of 1976, FLPMA) and their impact; the invention of Class I, II, and III inventories; and the rise and fall and re-introduction of modeling approaches to cultural resource identification. We ground our review in the present with a look at the emergence of “landscape-scale” development proposals and we conclude with some thoughts on the Bureau’s, and our, response to this challenge.

[333] Material Culture of Public and Private Spaces in the Mesa Verde Region
Material culture can inform on social integration and disintegration of communities. By comparing material culture from public and private spaces, we can better understand social relationships, including community integration and changes in integration through time. In this paper, we explore differences and similarities in material culture associated with public and private architecture in the Goodman Point Community in the Central Mesa Verde region of southwestern Colorado to better understand the integrative functions of public architecture. By exploring the distribution of various types of artifacts across the Goodman Point Community, we evaluate the connections between material culture and architecture. Are particular pottery designs, pottery vessel forms, or stone tools associated with public spaces more than private spaces? Do these patterns reflect the integrative functions of public spaces? Do patterns change with disintegration of the community, just prior to regional depopulation? In this paper, we present data on various types of artifacts, including pottery, stone tools, and ornaments, to evaluate both contemporaneous and diachronic use of public and private space within the Goodman Point Community.

Schlichtherle, Helmut (Landesamt für Denkmalpflege Baden-Wuerttemberg)

[246] Neolithic Settlement Patterns in the Federease Region, Upper Swabia (Germany)
During the Early Neolithic (following 5500 B.C.), the most intensive settlement of southwestern Germany occurred in areas of loess soils along the Danube, Neckar and Rhine river systems. The Federease area in the alpine foreland remained relatively unsettled. End Mesolithic hunter-gatherers persisted here, whereas Early to Middle Neolithic archaeological material (5300-4500 B.C.) is very scarce. But from 4200 B.C. onwards, the Federease offers an important window into Late Neolithic settlement, as sites from this period are well preserved in the wetlands here. Whereas early investigations concentrated on the reconstruction of houses and settlement plans, research from 1980 onwards, combined with dendrochronology and bioarchaeological data, have provided deeper insights into settlement structures, settlement dynamics and landscape changes. Now, repeated occupation of the Federease basin during various phases of the Late
Neolithic (4200; 4000-3850; 3745-3650; 3340-2900; 2900-2800 B.C.) can be demonstrated and new settlement system models discussed.

Schloen, David (University of Chicago)

[65] The Data Lifecycle at Zincirli (Iron Age Sam'al) in Turkey
Since 2006, a University of Chicago team has been conducting excavations and geophysical surveys at the 40-hectare site of Zincirli (the walled capital of ancient Sam'al) in southeastern Turkey. Data from the excavations and surveys, including all photographic and spatial data, is recorded and integrated via an online database system called OCHRE (Online Cultural and Historical Research Environment). This system, which is currently being used by several different archaeological projects based at different universities, is hosted and professionally managed on a database server at the University of Chicago Library. This paper will illustrate the use of the OCHRE system for field archaeology by presenting the complete data lifecycle at Zincirli, starting with initial data recording at the site via offline tablet computers and aerial photogrammetry, followed by automatic uploading of data to the Chicago database server on a daily basis, after which the data is immediately available in the dig house for online use and analysis by the field team, who can then correct and augment it as needed.

Schmader, Matthew (City of Albuquerque)

[323] Slingstones and Arrows of Contact and Conflict: Coronado in the Rio Grande Valley, 1540-1542
Instances of first contact by outsiders on indigenous peoples are uncommon historically and rare archaeologically. The Contact period in the American southwest lasted from the mid-1530s to the early 1590s. The most important expedition of the southwestern Contact period was led by Francisco Vázquez de Coronado from 1540-1542. His force of 375 Europeans and 1,300 Mexican soldiers arrived in the Rio Grande valley with disastrous consequences for the pueblo people. Investigation at one pueblo village near Albuquerque NM has identified a battle site with European weaponry and artifacts related to fighting between indigenous forces on both sides. European artifact types include lead musket balls and crossbow arrow points, which are found in context with indigenous weaponry such as projectile points and slingstones. These artifacts are found in patterns relative to site architecture, which suggests the structure of conflict-related tactics. Examination of expeditionary documents provides insight about some of these artifact distributions.

Schmaus, Tekla (Indiana University)

Was prehistoric Semirech'ye a shatter zone? Or was it a hub of power in the pastoralist world? Or another sort of place we haven't even imagined? How would we tell, and how much information would we need to feel confident in our answers to these questions? We have access to a broader range of data than our predecessors did, but we still have less material available to us than do our colleagues working in other places. How much can we say about past lifeways when our datasets are limited in scope? This paper approaches these questions using results from a study of dental annuli in domestic sheep as a starting point. The annuli data are indicators of people's seasonal occupation at three settlements in Semirech'ye during the Bronze and Iron Ages. The nature of the datasets limits what it is possible to say about people's lives beyond basic settlement patterns. However, that does not mean it is impossible to apply the information to questions of broader interest. Doing so with a clear understanding of the potential and the limits of the data may even lead to interesting new interpretations of past people's social and political entanglements.

Schmid, Magdalena (University of Iceland)

[29] The Impact of Volcanic Events on the Landnám: Did Eldgjá 938±4 A.D. Stop the Colonization of Iceland?
Traditionally, the Scandinavian migration and settlement of Iceland in the Viking Age is dated according to Íslendingabók between 870 and 930 AD. Some settlements are sandwiched between the so-called landnám tephra layers - now dated 871±2 AD by correlation to the Greenlandic Ice Sheet - and several tenth century tephra layers: K-920, E-938±4 and V-940 AD; these tephra layers at least partly confirm the historical dating. The explosive 934 AD Eldgjá basaltic flood lava eruption was the largest on Earth in the last millennium. The Eldgjá fissures produced 19.6 km3 of basalt in a prolonged eruption that featured several distinct episodes and may have lasted for 3-8 years, releasing a huge amount of sulfur into the atmosphere. This paper primarily discusses the intensity of climatic effects from the Eldgjá event and their
impact on settlement and colonization. Further, human environmental impacts and economic crisis will also be discussed in the context of the eruption, through the study of soil sediments and archaeological evidence. Conclusions will be made regarding how these factors may have led to individual settlement abandonment or even to the end of widespread colonization in Iceland.

Schmidt, Erin (New Mexico State University)

An Examination of Hacienda Architecture in Yucatán, Mexico

This paper presents archaeological and historical evidence of the changing roles of haciendas in the Mexican economy during the nineteenth century in Yucatán. Specifically, this paper looks at how haciendas changed before and just after the Caste War of Yucatán. Haciendas are agricultural estates that are maintained by a wealthy land-owner and a lower-class labor force to supply small-scale markets with goods and enhance the prestige and status of the owner. The spread of haciendas across Yucatán was a process related to changes brought on by shifts in capitalist relations among owners and workers that occurred during the Industrial Revolution. I compare the variation in the architecture of the haciendas before and after the Caste War (1847), in the areas around Yaxcabá and Valladolid. Architectural variation reveals new details about labor organization and production during the volatile nineteenth century. As knowledge regarding haciendas increases, new questions arise about their structure and functions across time and space.

Schmidt, Peter (University of Florida) and Benjamin Shegesha (Katuruka Preservation and Conservation Association)

Mutuality, Reciprocity, and Local Needs: Missing Spokes in the Collaborative Wheel?

The rhetoric of collaboration in anthropology and archaeology often masks practices that do not fall within the realm of mutuality and reciprocity. Archaeologists using this trope often employ it to reference research conditions where they take the initiative and local "participants" follow along. Mutuality is rarely integrated into collaborative programs, as research agendas continue to be Western-driven and dominated in decision-making. Such empty posturing threatens the integrity of mutual needs and reciprocity and makes diaphanous the absence of benefits accruing to local communities. I examine how such rhetorical traps may be avoided through collaborative research that meets community initiatives, desires, and articulated needs. Examples from western Tanzania show that collaboration in heritage studies and archaeological research satisfy deeply felt needs in communities searching to reconnect to their quickly atrophying heritage and seeking ways to reclaim, through local management of heritage sites, a modicum of economic stability that once marked the region as one of the most prosperous in East Africa.

Spanish Missions within California’s Indigenous Landscapes

Continuing research on the archaeology of colonialism is rethinking the ways indigenous communities in North America creatively engaged colonial programs. Examining Spanish missions in particular, archaeologists are investigating themes of social persistence and power relationships and also re-evaluating the broader geographic relationships between mission communities and the numerous outlying native spaces. Examining Spanish missions within indigenous landscapes, this paper addresses the broader footprint of missionization in California through a critical look at the exchange and circulation of marine shell and glass beads taking place between hinterland native villages and colonial sites. In rethinking and re-exploring the sites and artifacts of mission-era indigenous places, we can more fully understand-and establish more relevant archaeological projects addressing-the practices, experiences, continuities, and adjustments of post-mission California Indian communities.

[243] Reading an Ancient Face: Networks of Knowledge, Public Healing, and Conceptual Metaphor

The study of metaphor adds depth to social histories of power and scale and to intellectual histories of knowledge and its transmissions by focusing attention on conceptualization. With conceptual metaphor, the iterations that people made from one part of the common phenomenological ground on which they lived life to another, made history, language, things and society along the way. This paper develops a methodology for the historical study of conceptual metaphor in Africa’s early history. The specific case at hand—“reading” a group of terracotta figures (including a human head) and decorated pots—draws on deep, regional histories and on far-flung networks with multiple roots. The paper’s central historical conclusion finds that the practice of representing territorial spirit mediums as clay figures provided a valuable durability to communities living in the increasingly mobile worlds of 10th to the 12th century in the Lake Victoria region. But it grew risky to communities seeking to expand the scales of political economy using collective violence, in the 13th and 14th centuries when relatively richer water budgets returned to the region. So, they abandoned the practice. “They” were communities of public healers built around practices of social criticism whose improvisations transformed the scale of political affiliation.

[127] Paleoclimate during Neandertal and Anatomically Modern Human Occupations in Israel: The Stable Isotope Data

The δ13C(en) and δ18O(en) values of goat enamel carbonate indicate that Neandertals from sites in Israel (Amud and Tabun Level B) and anatomically modern humans at Qafzeh lived under different ecological conditions. Neandertals lived under wetter conditions than those in the region today. Anatomically modern humans encountered a region that was more open and arid than occurred during the Glacial Period, and more open than today’s Upper Galilee region. Climate differences affecting the distribution of plants and animals appear to be the significant factor contributing to behavior differences previously documented between Neandertals and anatomically modern humans in the region.

[66] Variability in Mimbres Food and Food Procurement

Archaeologists working in the Mimbres region have made important contributions to the study of prehistoric subsistence and social organization. Mimbres Foundation researchers were among the first to recognize temporal changes in Mimbres subsistence and link them to climate, environmental, and social change. Prehistoric changes in the Mimbres Valley included increased weedy plant ubiquity and proportions of small mammals from the Pithouse to Classic periods, and the occurrence of lasting anthropogenic soil change. They also found spatial patterns in resource availability and use, such as in soil use by farmers and spatial differences in wild plant and animal resources. Subsequent research has explored similar themes in a broader spatial and temporal context. Temporal changes in wild plants and animals from around the Mimbres region are generally consistent with patterns observed in in the Mimbres Valley, but are less pronounced in outlying areas. Farming practices also differed between eastern and western Mimbres. Post-Classic shifts in subsistence and food procurement are another topic of recent research outside the valley. Major questions about Mimbres subsistence, from both wild resources and agriculture, remain.

[193] Investigating Cultural Transmission among historic New England Gravestone Carvers with Social Network Analysis

One challenge for applying evolutionary models to culture is connecting individual learning processes with population-level cultural patterns. However, we have few examples of material culture traditions that can be tied to individual artifact producers. With this in mind, we used gravestone decoration and social network analysis techniques to model social learning pathways among gravestone carvers working in the Boston area during the seventeenth and eighteenth centuries. Surprisingly, the analysis reveals that processes of social learning differed at macro (motif) and micro (decorative element) levels of stylistic variation. Gravestones securely attributed to carvers exhibited very little decorative variation in motifs, which suggests widespread transmission among workshops. In contrast, individual stylistic elements are shared by carvers in the same workshop—a pattern that is consistent with the transmission of such traits within workshops. These results suggest that further applications of cultural transmission theory in archaeology must recognize that artifact design can result from multiple individual learning processes at work simultaneously.

[89] The Role of the State in Reducing Transaction Costs: A Case Study from the Bronze Age

In response to the dominant view held by archaeologists that defines the state in coercive terms, a growing body of research has emerged emphasizing collective action and cooperation as driving the state enterprise. From this perspective, one role of the state is to provide and maintain public goods. Among these, the maintenance of roads and the establishment of standardized measures serve to reduce transaction costs, i.e. the costs of engaging in economic exchange. Since these public goods were not excludable, they offered equal benefits to state elites as well as those outside the governmental apparatus. Using the nascent states of Mycenaean Greece as a case study, this paper examines the effect of reduced transaction costs on economic growth— one possible indicator of a successful state. I argue that instances of such “win-win” scenarios provide an under-researched complement to the “zero-sum” approaches of traditional theories of the state. Moreover, the archaeology of the Bronze Age, the period when the first states appeared, offers special insights into the emergent properties of large-scale cooperative institutions.

[161] Research on the Copper Producing Area at El Coyote, Sta Barbara, Honduras

In 2002, evidence of copper production, in the form of slag, was found on the surface of the southeastern portion of the site of El Coyote in NW Honduras. Test excavations that year revealed more slag and a piece of purified copper; soil tests also outlined the general extent of production. In the subsequent 2004 season, slag, ore, and processing facilities were located, as was evidence in other parts of the site indicating that the copper production was pre columbian. In 2013, further excavation uncovered more workshop areas, and XRF examination of ores, melting vessels, and soils further clarified the technical details of manufacture as well as defining the zone of concentrated production. Also, investigations to the north and west of the production area amplified the context for copper working here. This paper reviews the evidence for copper production at El Coyote, and places the work in both physical and temporal contexts.

[264] Geomorphic Change and the Regional Environmental Context at La Playa, Sonora, Mexico

Geoarchaeological work at the site of La Playa in Sonora, Mexico has resulted in an understanding of the formation processes and depositional environment of the site. The principal occupation of the site was during the Early Agricultural period (3650-1800 cal BP), and an extensive canal system dates to this time. The floodplain on which the site is located was formed by deposition of low-energy overbank deposits between 4000 to 1600 cal BP. The slow and steady deposition of fine-grained sediments likely contributed to the stability of the floodplain, making this an attractive location for canal agriculture. This period was followed by higher energy deposition and extensive cut and fill erosion. In the Southwest,
periods of aggradation and erosion in alluvial deposits are often correlated with regional climatic changes. This paper examines the regional environmental context of change in deposition at La Playa. The alternating episodes of higher and lower energy deposition do not correspond well to cycles of alluvial cutting and filling in the greater Southwest, but the fine-grained deposits at La Playa do correlate with low magnitude flooding in the Southwest. The fine-grained deposition may have been further controlled by the extensive canal network.

[27] Public Spaces in the Wari Empire
When the Wari Empire expanded across the Central Andes in the Middle Horizon (AD 700–1000) it built administrative facilities ranging from small structures to town–sized centers. Spaces within these facilities were given over to state functions, including elite housing, food production, storage, etc. and certain areas appear to have been devoted to more public activities including feasting and ceremonial rites. This paper explores the architectural distinctions of such spaces, their layout and spatial syntax, and the social order implied. While Wari did not have plazas in the usual sense, they did employ certain spaces to enable particular forms of ritual communication and interaction among groups of people. These spaces created and reinforced the new political and cosmological order imposed by the Wari regime.

Schroeder, Whittaker (University of Pennsylvania)

[311] Stone Spheres and Sacred Landscapes in Southwestern Costa Rica
People typically view monuments as large, static objects, designed to commemorate the activities of a person or an event. However, monuments rarely act alone, and their existence as highlighting an already meaningful place reveals the inherent bonds that form between monuments and their associated landscapes. Much of the object’s biography was created in the actions that occurred before it was placed in its “final” site, after which meanings and uses could shift repeatedly throughout its afterlife. Thus, the key to understanding monuments is through a multi-scalar landscape approach, which focuses on the transformation of space into humanized place, a process in which individuals ascribe meaning and power to the environment through its modification. In the Diquís Delta of southwestern Costa Rica, landscape archaeology can be combined with contemporary indigenous views of sacred places to reflect on the study of the stone spheres found throughout the region, adding to their site context in an attempt to reconstruct the values and meanings behind these enigmatic objects. The present study applies GIS and remote sensing techniques to the stone spheres originally documented by Doris Stone and Samuel Lothrop and examines Boruca and Bribrí concepts of space to test various interpretations regarding these monuments.

Schroeder, Jessy (Eastern New Mexico University)

Museums have long been institutions that display and educate the public on artifacts, objects, flora, fauna, and technology. Archaeological museums are one of the few reliable resources that the public has access to in order to learn about and better understand past and present human cultures. As important archaeological and educational destinations, every archaeological exhibit should be analyzed for how well they present their information. Therefore, this research will aide in answering the broader question of what and how audiences learn information put forth in archaeological museums. The intent of this study is to answer whether or not specific museums within the Llano Estacado region of the United States are effectively achieving their educational goals. Specifically: are the visitors learning what the museum curators want them to learn? And what visual aspects of explanatory labels help or hinder visitor learning? This study involves interviews with the curators, surveys completed with visitors, and visual analyses of explanatory labels in each museum. The data will be compared in order to determine whether or not each museum is effectively communicating its information, thus effectively educating the public.

Establishing 3D Unit Space from Low-Tech Field Data Acquisition Methods Using Post-Processing in GIS: A Case Study of Site MV-206 (La Quemada, Zacatecas, Mexico)

Spatial analysis of intrasite artifact distribution is essential to the discovery of activity areas. Difficulty in establishing confidence in potential activity areas increases as artifact spatial resolution decreases. In the archaeological record and at ongoing/future excavations, artifact provenience at a three-dimensional point resolution may not be possible, resulting in the excavation unit as the highest level of artifact spatial resolution. In this paper, we present methods for automating the creation of 3D unit space through post-processing. We present a methodology that utilizes Geographic Information Science (GISc), through an overall implementation of the Knowledge Discovery in Databases (KDD) process. As a case study, we use the archaeological record from MV-206, a large village outlier of La Quemada in Zacatecas, Mexico. Here, unit space was explicitly defined by a methodology that included a strict grid/artifact provenience and planar base definition. Additionally, the site’s relatively short [major] occupation manifested in shallow deposition, combined with the site’s substantial range and density of artifact types, allows for statistically significant spatial analyses at the excavation unit level. Identification of meaningful spatial patterns within low-resolution data sets presents new possibilities for intrasite analyses, and helps shape future site data acquisition methods.

Geoarchaeology, Forensics, and the Prosecution of Saddam Hussein: A Case Study from the Iraq War, 2005-2008

During the Iraq war, the U.S. government dispatched teams of forensic archaeologists and anthropologists to examine a series of mass graves, ostensibly representing the victims of genocide perpetrated by the Saddam Hussein in the latter 20th century. Prima facie evidence in support of mass graves was as compelling as it was fragmentary. The mobilization of teams in a war zone required that the strategy for making a legal case involved merging the most efficient technologies in use by archaeologists and forensic scientists. A central hypothesis in the Research Design was a landscape-based approach positing that selection of a mass burial site was well thought out. The site’s landscape elements were key to understanding planning strategies and efficient disposal of large numbers of bodies. Further, an examination of the burial fill sequence, the content of disaggregated residues, and the matrix of the overburden contained evidence bearing on grave preparation, sequential body disposals, and post-interment re-landscaping to camouflage the scene of the crime. Taken together, these data provided an evidentiary baseline for the ultimate conviction of Saddam Hussein and his henchmen. The lessons learned over the course of this study provide a blueprint for practical, critical applications of geoarchaeology going forward.

Castro Colonies Living History Center, the Jacob Biry House, Castroville, Texas: A Preliminary Investigation

Under a commission from the Republic of Texas, Castroville was founded by empresario Henri Castro in 1844. The community was settled by primarily immigrant Catholic Alsatian farmers and the connection to their Alsatian heritage remains strong to this day. The Jacob Biry property is located in the town on a 1/3 acre plot. It consists of two standing structures: a stone house and a dogtrot log cabin both reputedly dating from the 1840s and associated with the initial settlement of the town. A stone smokehouse
foundation is visible in the backyard, and local informants have described the historic presence of privies, wells, cisterns, and a garden. Preliminary archaeological and dendrochronological fieldwork was conducted in January 2013. An electromagnetic resistivity survey and systematic auger testing were utilized to determine soil horizons, and identify locations and extents of buried subsurface features. As a result, 8 subsurface features were located. A detailed architectural recording of the dogtrot cabin was performed and 46 tree-ring samples were taken to help determine the age of the structure. These initial investigations provide the groundwork for a more in-depth archaeological project at the property designed to include and engage the local community in their history and heritage.

Schumacher, Jennifer (McMaster University)

[261] Same Puzzle Pieces Different Puzzle: Extant Collections

The future of archaeology lies not only in further excavation but also in revisiting past research and excavations using innovative methodological techniques and theory. With increasing funding restraints, the re-evaluation of extant collections has become practical and therefore more attractive. Using the approaches of technological style and consumption I demonstrate how utilizing extant collections can shed new light on academic debates and the pragmatic issues concerning their use. I demonstrate this with a case study of an Ontario Early Late Woodland site, Van Besien. Since potting is a social event involving transmission of knowledge, production exists within social constraints specific to each potter and influences the technological choices he/she makes. Such technological choices cumulate in what is regarded as technological style, created by the repetition of activities or choices that create discernible patterns. These patterns allow for identification of styles that demarcate social boundaries. Due to these new approaches, levels of homogeneity unprecedented in Ontario during the Ontario Early Late Woodland were discovered as well as unexpected social divisions within a village. This study represents a successful re-evaluation of an extant collection and how with new approaches new interpretations can be discerned.

Schurr, Theodore (University of Pennsylvania)

[69] New Genetic Perspectives on the Colonization of the Americas

The key issues for understanding the prehistory of the Americas are the number of migrations that contributed to the diversity of Native American populations and the time at which the ancestral population(s) initially entered the New World. Recent analyses of mtDNA variation generally support the Beringian Incubation Model, in which the ancestral population entered the Americas some 20,000-15,000 YBP after having genetically diverged from sister populations in Asia. By contrast, recent osteology and nuclear genetic studies suggest that two or more population expansions gave rise to the biological diversity in the Americas. We re-examined these issues through high-resolution analysis of mtDNAs and Y-chromosomes from populations inhabiting the Arctic, North America and Mesoamerica. This analysis revealed distinct sets of maternal and paternal lineages in these regional populations, with new branches of Y-chromosome haplogroups Q-L54 and Q-M3 being identified in them. Those lineages observed in the circumarctic region reflected population expansions occurring over the past 5,000-10,000 years, and possibly recurrent gene flow from Beringian or Northeast Asia. These data have important implications for the timing and process of the colonization of the Americas, and, in particular, the type and number of founding genetic lineages which first reached this region.

Schurr, Mark (University of Notre Dame)

[303] The Juxtaposition of Stable Isotope and Mortuary Analyses: Illuminating Social Transformations in the Late Prehistoric Southeast

The end of the prehistoric period in the Southeastern United States was a time of regional social transformation. Throughout the region, hierarchically organized Middle Mississippian chiefdoms with ascribed ranks maintained large sites and aggregated regional populations that were replaced by less hierarchical groups with more dispersed settlements. The changes in social organization and landscape use are generally understood, but the processes that produced and accompanied these transformations remain unclear. In southwestern Indiana, on the northern border of the Southeast, the Angel chiefdom was replaced by Caborn-Welborn phase peoples across part of the Angel chiefdom’s range. Both groups (Angel and Caborn-Welborn) recruited or attracted people from other areas. Thus, regional patterns of population movement played an important role in the development of one Middle Mississippian society and its successors. Mortuary contexts and patterns of variation in human diet (as reflected in stable carbon- and nitrogen-isotopes from 282 individuals) are juxtaposed to illuminate how this type of social change occurred. The demographics of recruitment are reflected in mortuary patterns and human diet in ways that appear contradictory to what might be expected from each phase’s need for more members.

**A Regional Analysis of Ancient Maya Mortuary Practices from the North Vaca Plateau, West-central Belize**

Excavations by the Social Archaeology Research Program in the North Vaca Plateau of Belize over the past 15 years have revealed a rich mortuary record for the people that lived at the sites of Minanha, Ixchel, Martinez, and Waybil. Human remains have been discovered in a variety of contexts, spanning the Preclassic to Postclassic Periods. In this paper, we argue that the most meaningful scale of analysis of these remains is the regional scale, incorporating data from multiple sites in the region, including both large settlements (Minanha, Ixchel) and small (Martinez, Waybil). In addition to the spatial distribution of remains, careful consideration of the associated material culture and the basic mortuary patterns of grave orientation, location, and complexity of construction have given us the ability to characterize this region’s mortuary practices as distinct in some ways from other areas of the Maya world. At the same time, some overlap in these regional mortuary practices ties the Maya of the North Vaca Plateau into larger spheres of interaction with some of the big players within the Maya socio-political landscape.

Schwalenberg, Megan (University of Wisconsin - La Crosse)

**A Comparative Analysis of the Dental Health of Two Middle Woodland Burial Populations in the Lower Illinois Valley**

The Gibson and Ray sites are burial sites located in the lower Illinois Valley and dated to the Middle Woodland period, ca. 50 B.C.–A.D. 400. Through the examination of 48 skeletons, this study compares the dental health between the two sites in terms of dental pathologies and their potential correlation to either site, sex, age-at-death, or all of these. Information on dental attrition, caries, abscesses, and other dental pathologies was collected from a pre-selected sample of 24 adults from each site, and estimation of sex and age-at-death were established with two age groups: young adults (20-35) and middle-to-old adults (35-50+). These results suggest there was little to no dietary difference between the sites and that poor dental health was prevalent among middle-to-old adults. Higher attrition rates found at the Ray site can potentially be explained by a different food processing technique or a slightly different diet. This information provides insight into the dental health of the Middle Woodland people during the transition from hunting-and-gathering to horticulture in the lower Illinois Valley and a baseline that can be utilized by other researchers for comparison to later maize agriculturalists in the region.

**Vernacular Architecture of Southeast Mesoamerica: An Evaluation of Design Variations and Identity Expression from the Late and Terminal Classic Naco Valley, Honduras**

Architectural designs and site-planning principles have been well studied in Mesoamerica, however, our knowledge is based predominantly on the archaeology of large urban polities, monumental styles, and elite-associated contexts. A standardization of the architectural canons of domestic, rural, and/or household milieus remain underexplored, especially within southeastern Mesoamerica. The approach of evaluating vernacular architectural traits from this particular region of the Pre-Columbian Americas promises to initiate the decipherment and systematization of construction similarities and variations from “everyday” settings. Therefore, this paper will present an analysis of the vernacular architecture from the Late and Terminal Classic site of PVN647, located within the eastern region of the Naco Valley in northwest Honduras. Of particular focus will be the assessment of architectural feature design, location, construction quality, temporal order, and function. These aspects will be examined both within and between patio and plaza arrangements within the site. Additionally, intra- and inter-valley comparisons will be explored to reveal the extent of regional architectural design correlations. This discussion advances our understanding of the elasticity of shared identity expression to meet local ideals, as interpreted from the ancient material record, as well as the cultural and ethnic diversity from this region of southeastern Mesoamerica.

[329] Unpacking Uruk Exchange Networks: The Use of Functional, Spatial, and Bulk Stable Isotope Analyses of Bitumen Artifacts from Hacinebi Tepe, Turkey in Reconstructing Broad Economic Patterns of the Uruk Expansion

This research addresses the economic expansion of state societies from southern Mesopotamia into southwest Iran and southeast Anatolia, through the use of stable carbon and deuterium isotope analyses of bitumen artifacts. The key goal of the project was to get beyond simply the identification of trade and examine broad regional patterns in the exchange system. To this end, the methodological approach of this research was focused on the reconstruction of general exchange patterns using a large sample set. The results of these analyses suggest the utility of bulk isotopic analyses in the identification of broad regional patterns, serving as a complement to detailed isotopic and molecular work on asphaltene extractions of bitumen. The source identifications presented in the paper were further supported by gas chromatography-mass spectrometry as well as compound specific isotope analyses. Furthermore, because bitumen was employed in a variety of ways in the ancient Near East, including as a packaging material for other trade goods, a spatial-functional analysis of bitumen artifacts, combined with geochemical data allows for a range of questions to be addressed. The results of this research indicate changes in the organization of trade at the site of Hacinebi associated with the Uruk expansion.

[289] Comparing Demography and Population History between the Northern San Juan and Northern Rio Grande

Using Bayesian statistical methods, we reconstruct the population history in the two Village Ecodynamics Project study areas: a 4,569-km² area in the northern San Juan and a 6,955-km² area in the northern Rio Grande. In the north we apportion population from nearly 8,000 sites across 14 time periods between C.E. 600–1280 and examine demographic trends across 6 subregions: (1) McElmo, (2) Mesa Verde National Park, (3) Dolores, (4) Hovenweep, (5) Mancos and (6) the Ute Mountain Piedmont. In the south we apportion population from approximately 2,000 sites between 17 different time periods between C.E. 900–1760 and examine demographic trends across 5 subregions: (1) Chama, (2) Pajarito, (3) Santa Fe, (4) Cochiti, and (5) Velarde. In the north we see episodes of population growth and decline, with a smaller peak in the late 800s and a larger peak in the mid-1200s. In the south, we document population growth that coincides with the depopulation of the northern area and population decline that begins before Spanish arrival. We interpret the timing and similar magnitude of peak population between regions as evidence of migration from the northern San Juan to northern Rio Grande.

[330] The Tourist Commodity: The Value of Handicrafts in Yucatán’s Puuc Region

The steady rise in tourism in Yucatán beginning in the 1960s has made producing and selling handicrafts a profitable industry and an appealing alternative to other lines of work available. Naturally, the marketing of Maya history, the people and their traditions within the tourism industry has influenced the kinds of artistic objects that are produced and sold within Yucatán. As such, value systems are based on what tourists perceive to be ‘authentic’ remnants of Maya culture, so contemporary artisans create replicas and other pieces with stylized Maya imagery - in stone, wood, ceramic, plaster, gourd, and others - that will appeal to this notion. By focusing on the handicrafts produced in Yucatán’s Puuc region, this paper will examine them within larger fields of cultural production and will show how the agency of artisans - their strategic marketing techniques and forms of presentation and display - likewise influence and shape the way tourist outsiders view and understand contemporary Maya people and their culture. In this context, the complex network of cross-cultural encounter, social relationships, economic transactions, and the local and institutional discourses that create and assign value to handicrafts in the Puuc region will be considered.

[33] A Historical Retrospective of Mesoamerican Cave Archeology: Celebrating James Brady’s Contributions to the Field

The history of cave investigations in Mesoamerica, especially in the Maya area, cannot be written without acknowledging the corpus of work penned by James E. Brady. The more than 125 publications, spanning thirty plus years, have transformed speleoscholarship with new and unconventional ideas
about the ritual use of caves by the ancient Maya. Significant growth within the field has been influenced
by Brady's own academic interests including the study of cave pilgrimage, man-made caves, the
ethnography of cave rituals, iconography and epigraphy, and the relationships between surface
architecture and caves in the sacred landscape. His influence has touched numerous scholars leading to
several co-authored publications and has inspired many students to pursue a path into the darkness.
This presentation sets the stage for the papers that follow by providing a brief history of cave studies
along with a short literature review of Brady's bibliographic portfolio. A celebration of Jim Brady's 30
years of achievements, contributions, and scholarship would not be complete without testimonials from
colleagues, friends, and students whose destinies have also included dark passageways.

A Battlespace Model of the 1865 North Platte Campaign

Conflict is an important human behavior that leaves clear, interesting, and concrete material traces.
Archaeologists have developed means of exposing and interpreting the record of past combat. This study
presents archaeological data from battles that took place in February 1865 in the North Platte Valley of
Nebraska between Union cavalry and Cheyenne forces reeling from the Sand Creek tragedy.
Archaeological data, presented in landscape terms, arrayed with modern graphic techniques, and
interpreted with conceptual tools that address military issues, offer specific insights in to the thinking of
the people who fought these battles.

Scott, Jannie

Freedom's Institutions: The Archaeology of Antioch Colony's First School and Church

Since the late 1960s historical archaeologists have made great strides in bringing light to the lives and
conditions of Africans and their descendants in the "New World." In archaeological texts, however, focus
on Black institutions created by and for African Americans are largely absent in discussions of the history
of Black Americans in the United States. This paper focuses on the archaeology of a historic school and
church located in Antioch Colony. Antioch Colony was a vibrant rural freedmen’s community located in
Central Texas formally established in 1870. How can archaeology be used to understand the importance
of education and religion within an African American community during the early post-emancipation time
period?

Scott, Rachel (DePaul University) and Alexander Bauer (Queens College)

Archaeology Should Be Anthropology: The Benefits of Four-Field Training

The field of anthropology has become increasingly fragmented in recent years, challenging the coherence
of the four-field approach and archaeology's place within it. In opposition to this deconstruction, we argue
that four-field training provides key benefits for education, employability, and research. To illustrate these
points, we draw on our own experiences as students, researchers, and advisors. When taken as part of a
larger anthropology curriculum, archaeology courses help students to see the connections between the
past and present, encouraging their development as world citizens and preventing archaeology from
becoming an esoteric discipline. Moreover, a basic understanding of all of anthropology can improve a
graduate's chances of attaining a tenure-track position, particularly in smaller departments where a
broadly-trained applicant may be expected to teach a variety of introductory courses and communicate
with colleagues in other sub-fields. Finally, engagement with multiple aspects of anthropology enables
scholars to push the boundaries of archaeological research by asking new questions and incorporating
external methods and theories. Because of these benefits, we contend that archaeology should seek to
strengthen its bonds with the other sub-fields of anthropology rather than allowing them to disintegrate
through increasing specialization.

Ancient Blackwater Draw Sediments Reveal their Age and Clues to Paleoenvironment

Stored in a plaster jacket applied in the field, sediments removed from Blackwater Draw recently revealed
the first Clovis age radiocarbon date from this site (11095 ± 35 RCYBP). In general, pollen and phytolith
records combine to indicate paleoenvironmental conditions for the Clovis period in the Blackwater Draw
Locality and Frost Arroyo that are unlike those of today. Open or ponded water, vegetation communities reflecting marshy areas along the margins of the water, and evidence for drier habitats outside the wetlands all were noted in this study. Phytolith analysis for the Folsom Block yielded evidence of an open lake or pond teeming with algae and aquatic plants. Sedges dominated the lake margin during the earliest period of time, followed by a thriving community of common reed (Phragmites australis). The interpretation of open water is echoed in the pollen record by extreme dominance by Pinus pollen, representing wind transport of this pollen and accumulation on the water surface and by recovery of pollen from wetland plants such as cattails, sedges, common reed, and knotweed (Persicaria). Drier sagebrush vegetation communities grew adjacent to the wetlands. This description sets the stage for the Clovis occupation of Blackwater Draw.

[122] Moche Use of Multi-Media at Huaca de la Luna

Marshal McLuhan’s often-quoted “the media is the message,” insists that instead of producing new content, any new type of media creates new parameters within which human beings interact. Since human beings experience the world with all of our senses simultaneously, different types of media shape and orient the senses in particular ways and achieve particular effects via these configurations. Moche musical instruments greatly increase the range over which sound can travel, increasing the size of potential audiences and the impact of human sound. Moche architecture, such as the plazas and pyramids of Huaca de la Luna, directly control the scale of space within which people interact. Large wall murals allow groups of people to simultaneously view the same image. Smaller, portable objects, such as decorated ceramic vessels and musical instruments, allow an image to travel long distances. The semipermanence of images and architecture extend their communicative efficacy over time, while the ephemeral nature of sound connects an experience to a present action. Through the analysis of the acoustic properties of architectural space, music iconography and sound-producing objects, this paper addresses the question of what do the media of architecture, art, and sound communicate in a Moche context?

Sebastian, Lynne (SRI Foundation)

Many upper-division undergraduates and beginning graduate students in Anthropology have no clear idea about career paths other than the standard “academic teaching position” that will be available to
them when they graduate. In many academic programs, faculty members do not have the experience of
or knowledge about other career paths to enable them to guide the students in determining what future
path would suit them best. Indeed, some faculty members actively discourage students from pursuing
non-academic career paths. At the same time, private and public sector employers complain that they
cannot find new hires with even the most rudimentary knowledge about or experience in cultural resource
management. The SRI Foundation and the University of Maryland have teamed up in an
academic/private sector partnership to provide students with basic knowledge and skills, practical
experience, and the beginning of a professional network, as well as information enabling them to evaluate
a wide variety of career paths in CRM. The SRIF/UMD Summer Institute in Cultural Resource
Management, now in its fourth year, combines intensive classroom instruction and highly structured
internships, and is open to students from any college or university.

[334] Seeing Red: An Analysis of Ocher Treated Incised Stones Found within the Great Basin
Incised stones have been found at sites throughout the Great Basin dating from the Archaic period to the
Historic period. The purpose of these incised stones is unknown, although the deposition of the artifacts
does not suggest that they were used for rituals or were in any way sacred. Within the incised stone
artifact category there is a subcategory of the stones, those that have been treated with ocher. An
analysis of these rare ocher-treated incised stones, and the sites in which they were found, will try to
determine if the addition of ocher to the stones changed the meaning of the stone, or if the addition of
ocher was an artistic enhancement to the stone on par with painted stones that are found in the Great
Basin and the Southwest.

[66] Making the Transition: A Reassessment of Mimbres Pithouse-to-Pueblo Period
The Transitional (Mangas) phase, approximately A.D. 900-1000, has been a topic of some contention.
Originally, the Transitional phase, between pithouses and cobble masonry roomblocks, was defined as
small, surface cobble-adobe roomblocks associated with Mimbres Boldface (Style I-II) ceramics. Evident
in the Gila River valley, little evidence for a transitional phase was observed in the Mimbres River valley,
and the Mimbres Foundation, in its seminal chronology, omitted the phase, positing a very rapid shift from
pithouse to pueblo style sites. Later work in the Mimbres Valley revealed that Transitional period was
more diverse and widespread than originally thought. Work at NAN Ranch and the Harris site has found
evidence for the Transitional phase in the Mimbres River valley. But more substantial evidence can be
found in the upper Gila. Surface roomblocks with Boldface ceramics were found at the Saige-McFarland
site, and recent research at Woodrow Ruin is providing new insights on the Transitional phase. Woodrow
was continuously occupied from AD 550-1130, and excavation there has demonstrated that Transitional
architecture is more variable than previously expected. This paper discusses the history of research on
the Transitional phase, and examines how archaeological understanding of it has changed in light of
recent findings.

[291] Changing Conceptualizations of Kinship among Post-Meroitic and Christian Period Nubians from
the 4th Cataract Region, Sudan
Kinship systems are inextricably bound to cultural conceptions of age and sex. While recent research has
begun to emphasize the interconnections between multiple aspects of social identity, kinship has only
infrequently been used within archaeology as a lens through which to investigate changing age and gender
ideologies. This project combines data from cranial non-metric and odontometric traits with the age and
sex characteristics of individuals interred at the Ginefab School Site to investigate changes in the specific
biological relationships used to signal kin groups in the mortuary record from the Post-Meroitic period (ca.
A.D. 350-550) to the Christian (c. A.D. 550-1500) period in the Fourth Cataract Region of Upper Nubia.
Results demonstrate that genealogical relationships were emphasized in different ways in the mortuary
record of the Ginefab School Site through time, with a shift evident that temporally coincides with the
introduction of Christianity to the region. We discuss how the gender and age aspects of local kinship
systems responded to socio-political, religious, and economic transitions occurring during the Post-Meroitic
and Christian periods of ancient Nubia, as well as how these changes reflect the status of kinship as a
social identity incorporating multiple socially mediated interpretations of biological characteristics.

[276] Chemical Analysis of Chevron Beads from Early Sixteenth-Century Spanish Entradas into the Southeastern United States
Glass beads are one of the primary diagnostic material remains from the early European incursions into the New World. LA-ICP-MS (laser ablation inductively coupled plasma mass spectrometry) analysis of chevron beads provides insight into the movement of the Pánfilo de Narváez and Hernando de Soto entradas. Beads from sites associated with the Soto expedition have a relatively consistent chemical composition, which suggests a common source. Beads from the Wakulla Cemetery site (8WA15), a site suspected to be associated with the Narváez entrada, are chemically distinct from the de Soto beads. The variability in the chemical compositions of bead from the de Soto and Narváez expeditions are related to subtle differences in manufacturing techniques by individual producers. Analytical results will help trace the routes of early explorers in the Americas as well as indigenous trade routes. They also inform our understanding of 16th century bead manufacturing techniques. Our findings will shed light on nature of exchange between Europeans and indigenous groups in this early period of cultural contact.

Sejas Portillo, Alejandra (University of Pittsburgh)
[231] Changes in the Interactions Networks during the Late Period at the Southern Shore of the Poopo Lake, Bolivia
From early times Andean people have been moving between different ecological floors in order to obtain products that would complement their diet and also exotic goods for social differentiation. In this context, vessels of particular styles were circulating among different interacting communities located sometimes at considerable distances. The aim of this investigation was to study the effects of the Inka influence in the interaction network of the local population at the site of Tambo Viejo de Sevaruyo, the principal administrative site in the Southern Poopo Region, Bolivia. This poster presents the results of the technological and decorative analysis of ceramic material systematically collected at this site from the pre-Inka and Inka period; which made possible the identification of the provenance of this material with in these interacting areas.

[195] In Search of Kilns: The Forms and Functions of Annular Structures in the Bolonchen District
Over the last few decades, archaeologists have identified hundreds of annular structures throughout the Bolonchen District of the Puuc Region in the northern Yucatan Peninsula. Despite the ubiquity of these distinctive structures, which generally appear in the archaeological record as mounded rings surrounding a central pit, questions remain as to their full range of forms and the variety of functions that they might have served. Preliminary studies suggest that they were involved in the cooking process, but whether they were used in the processing of food, ceramics, quicklime, or a combination of these is yet
to be determined. Spatial analyses of the annular structures from the sites of Kiuic and Sayil indicate that at least some of the annular structures at these sites were most likely used as kilns for the processing of limestone into powdered lime. Previous studies of traditional methods for lime plaster production have demonstrated how the ancient Maya may have used open air pyres to produce powdered lime, but the identification of permanent ancient kiln structures remains unclear. If it does indeed turn out that these annular structures represent ancient kilns, they will be some of the first structures positively identified as such in Mesoamerica.

[301] Spatial Analysis of Monument Sites on the Dhufar Plateau: An Archaeological Application of Space Syntax Analysis

The early-middle Holocene of southern Arabia is difficult to discuss due to an incomplete and fragmentary record. It is known that the region was important on the larger scale because of its abundance of valuable frankincense, but without more information about the local mode of production, and their incumbent relations, we can only speculate on the role that indigenous societies played. The most prominent archaeological remains are megalithic monuments, representing social and ideological engagement with the landscape between the late fourth millennium and the late 1st centuries B.C. Investigations of neighboring regions have resulted in an intriguing scenario wherein mobile southern Arabian societies marked social transformation upon the physical landscape. This research models ancient mobility based on economic factors of production and the social configuration of space via the spatial organization of megaliths. Space-syntax analysis characterizes spatial systems on the ways in which spaces interact, which simplifies the arrangement of structures into nodes and linkages, thus describing relations of space using graph theory. Regional scale spatial analysis, surface monuments, and natural features all contribute to a mobility model. Change over time in mobility informs us as to the social context of first millennium relations of production between Arabian incense traders.

[140] Settlement Sequence at Gualupita Morelos

This poster will present the historical sequence of the Gualupita neighborhood in the city of Cuernavaca Mexico, form the Preclassic period until the establishment of the mega store COSTCO DE MEXICO SA de CV in to the region, showing the settlement sequences and the transformations that have come to pass in this area. The oldest archaeological information that we have from Gualupita neighborhood goes back to the Preclassic period (900 BC). During the archaeological excavations we were able to uncover the remains of a small Preclassic house; on the clay floor there was a large deposit of ash, indicating where the kitchen was located. Among other things we also recovered a series of Preclassic figurines, similar to those described by Suzannah B. Vaillant and George C. Vailliant during their excavations in 1934. After the Preclassic settlement, the Gualupita neighborhood was abandoned for many years, until the beginning of the construction in 1930 of the Casino de la Selva Building. This was going to be the first Casino in Mexico, but with the proclamation of the Federal law in 1947 that forbid gambling, the Casino had to close its doors.

[112] Interacción entre Xochitecatl-Cacaxtla y el Valle de Puebla-Tlaxcala durante el periodo Formativo

A traves de las evidencias arqueologicas de la cultura material del centro regional de Xochitecatl durante el periodo Formativo, intentamos explicar las dinamicas de interacción con los sitios contemporaneos del Valle de Puebla-Tlaxcala. Se trata de evidenciar las interacciones socio politicas de este centro, que
tanto por su localización, su arquitectura, la presencia de edificios ceremoniales, la variedad y cantidad
de tipos cerámicos locales y foráneos refleja una jerarquía sobre el resto de los asentamientos del valle.
Este centro regional que controla seguramente rutas de intercambio y abasto, se convierte en punto de
referencia y poder de la región durante el Formativo Tardío, hasta su desaparición por la erupción del
Popocatépetl alrededor de 200 años después de Cristo.

[295] The Application of Remote Sensing and GIS technology to Archaeological Research: Past,
Present, and Future.
Archaeology was one of the first disciplines to use aerial photography in its investigations at the turn of
the twentieth century. The low resolution of digital satellite technology that became available in the 1970s
limited its application to regional studies; however, that situation has changed. The arrival of high
resolution, multispectral capabilities of IKONOS, QuickBird, and other commercial satellites at the turn of
this century and the scheduled launch of new satellites in the next few years provides an unlimited
horizon for future archaeological research. The almost untapped potential that remote sensing, coupled
with Geographic Information System (GIS) technology and computer-aided analysis for the study of
human cultures seems beyond measure. Although many archaeologists are not comfortable with remote
sensing and GIS technology, a new generation is embracing it and archaeological projects of broader
scope than ever before envisioned are now possible as demonstrated in this session.

[198] Remote and Rugged: Historic Apache Landscape Strategies
Images of the Chiricahua Apache conjure the consummate opponent to the state, the iconic Geronimo
resisting to the end, maintaining autonomy long after others had surrendered. Their mobile lifeway
shields them from domination. The rugged and protective mountain landscape they used allowed the
Apache to avoid subjugation longer than any indigenous group in North America. Use of the international
border also benefited them, pitting two states against one another until cooperation between the US and
Mexico brought an end to that strategy. Apaches used elevation and remoteness to their advantage.
Changes in portion of landscape used and in fire-making behavior occurred as a result of changes in
pursuit strategies and commitment by opposing militaries (Spanish, Mexican, American states). The way
they distributed their housing across the landscape is directly related to expectations regarding enemy
incursions. The historic Apache are an outcome of their peripheral position relative to these states.

Seymour, Elizabeth (Utah State University)
[262] Variability in Pithouse Floor Area and Implications for Social Organization amongst the Fremont
Archaeologists use domestic architecture to enhance the study of social organization in ancient cultures.
Such investigations indicate that house floor area is one measure that proves useful in examinations of
social organization. This research compiles elements of Fremont domestic architecture routinely recorded
in archaeology and applies methods previously used in the American Southwest to examine social
organization in the Fremont culture. In particular, the variability in house floor area at Fremont residential
sites is used as a proxy for the level of participation in a corporate or network strategy. Data were
compiled by culling measurements of house floor area from cultural resource management reports and
forms at the Utah Division of State History and from published journals and theses.

Sgarlata, Cosimo (Western Connecticut State University)
[218] Evidence of Primary Forest Efficiency in Southern New England’s Late Archaic Period
In 2012 several Western Connecticut State University students participated in excavation at the Warner
site, a Late Archaic campsite in Woodbridge, Connecticut, securely dated between cal 4530 to 4420 B.P.
Analysis of stone cores, lithic debitage and tools indicated that lithic raw material was stockpiled; and
even high quality lithics were utilized almost exclusively for the production of simple, expedient flake
tools. In Southern New England, and many other parts of the Northeastern United States, the Late Archaic (6,000 to 3,700 B.P.) “fluorescence” has raised numerous questions due to the sudden and dramatic increase in documented cultural features, recovered diagnostic artifacts and reported radiocarbon dates. Analysis of lithic artifacts from the Warner site indicates that Late Archaic inhabitants practiced regularly scheduled seasonal moves, and centrally positioned camps adjacent to locations where a number of seasonally reliable resources were close at hand. However, although populations moved to new locations from season to season, evidence from the Warner site indicates that residential stability during particular seasons may have been an effective strategy allowing stockpiling of lithics. This, in turn, reduced time and labor expended searching for raw material and manufacturing formal tools, while maximizing efficiency procuring and processing foods.

Shafer, Harry (Texas A&M University Professor Emeritus) and Thomas Hester

Colha in Retrospective: Maya Lithic Craft Specialization

Colha is an ancient Maya town located in northern Belize. The economic importance of Colha is due to its setting. High-quality chert needed for axes, adzes, knives and spears, was abundant in large cobble and boulder-size masses and was easily obtained in a geographically restricted area within a very broad zone of settlements and polities. The technological tradition established at Colha may have seen its ultimate origin in the Preceramic period at the site, and expansion during the Middle and Late Preclassic led to the production of millions of stone tools that were dispersed to consumers throughout the region. Workshop production responded to supporting the needs of Terminal Classic warfare. This unique tradition became extinct with the destruction of Colha in the Terminal Classic. A new settlement was established in the Early Postclassic with an entirely different lithic tradition with origins in the Yucatan.

Unexpected Objects: Stone Tools in an Age of Gold

During the Irish Early Medieval period (ca. A.D. 400-1200), metallurgy flourished and artisans created exceptional products in silver, gold, and bronze. Trade from abroad also brought sophisticated ceramic wares from the continent and England. These spectacular items have been found during the course of excavation and have resulted in much research, while less attention has traditionally been paid to everyday, expected domestic finds such as locally made pottery and woodworking. Recent work collecting and synthesizing reports and grey literature by the Early Medieval Archaeology Project (EMAP) has made it possible to track the results of excavations dating to this time period and examine all objects, not just spectacular examples, in detail. Drawing on work by EMAP as well as the author’s own work in County Armagh, Northern Ireland, this paper examines an unexpected corpus of artifacts—lithics—utilized during this time period. Archaeologists have long assumed that lithic manufacture and use ceased during prehistory and yet increasing evidence suggests that stone tools were used well into the Medieval period, while metal tools were widespread. The use of lithics during this time is enigmatic, but may have been linked to socioeconomic status while also having ritual connotations.

Shakour, Katherine (University of Virginia)

Materialized Grieving: An Ethnoarchaeological Perspective on Village Residency, Westquarter, Inishbofin

The Irish Famine did not result in an immediate and total abandonment of rural coastal villages, rather it created the context for a complex interweaving of demographical, residential and immigration patterns that continue to unfold. Focusing on the small village of Westquarter, Inishbofin, County Galway, Ireland, this paper explores the social and residential history from around 1800 through the present day. Centered on the dynamic intergenerational shifts within and between families in the village, we track concurrent patterns of residential continuity among select family members, the relocation of other family members to other areas of Inishbofin, and the off-island migration of still other members to America, mainland Ireland, and England. Collectively the use of oral history, archaeological field research, historical maps, and local interviews provides new insights into how and why residential patterns change within a village, and the extent to which this can be linked to archaeological data sets. With these datasets we trace village history through ethnoarchaeological historical and documentary sources to understand the resulting social and political policies which created considerable, lasting social and economic changes.
Shakour, Katie [259] see Kuijt, Ian

Shankel, Sarah (Connecticut College), Tianna DiMare (Connecticut College), Anthony Graesch (Connecticut College) and David Schaepe (Stó:lo Research and Resource Management Centre)

The broader goals of household archaeology are predicated on the assumption that archaeologists can (1) discern among the material records of spatially discrete residential groups and (2) analytically isolate the constituents of living surfaces, refuse, and other behaviorally significant strata. This poster highlights research addressing the utility of soil penetrometers for recording and measuring variation in the compaction of living surfaces attributed to regular foot traffic in architectural features. Our data are drawn from subsurface investigations at Welqámex (DiRi-15), a large residential settlement spanning the Late and Contact/Colonial periods in southwestern British Columbia and featuring as many as five unique architectural styles. Variability in several hundred systematically sampled penetrometer readings is evaluated against other stratigraphic indicators of living surfaces, including non-cultural floor constituents (e.g., waterworn pebbles) and size-density profiles of frequently encountered residential trash (e.g., thermally modified rock and charcoal). We argue that penetrometers (1) provide supporting data for in-the-moment interpretations of strata revealed during plan-view excavation, and (2) show considerable promise for the analytic isolation of walkways and spatially discrete family areas in multi-family residential architecture.

Sharapov, Denis (University of Pittsburgh)

[20] Evaluating Social Developments of the Middle and Late Bronze Age periods (2100 B.C.-800 B.C.) in the Southern Urals, Russia, using Regional Settlement Pattern Evidence

This study utilizes Geographic Information Systems (GIS) techniques to analyze a regional (~4,400 km²) dataset derived from the systematic stereoscopic readings of Soviet-era aerial photographic images taken over the Kizil district of Russia (Zdanovich et al. 2003). In particular, the Kernel density function is used to evaluate the regional spatial distribution of hundreds of housing depressions, attributed to either the Middle Bronze Age (MBA) (2100BC-1800 B.C.) or the Late Bronze Age (LBA) (1800 B.C.-800 B.C.) periods, characterized by divergent patterns of social, political, and economic complexity. Comparing the settlement patterns in each period to the distribution of locally available subsistence and economic resources, utilized by the Bronze Age populations, allows to: 1) establish a link between resource-driven nucleation of the MBA populations and the resulting scalar effects associated with social complexity; 2) propose a hypothesis of gradual population disaggregation during the LBA, driven by a long-term trajectory toward extensive pastoralism.

[326] Where, Oh Where Did You Go? The Mystery of the Missing Methodist Meeting House

SWCA Environmental Consultants didn’t find the archaeological remains of the historic Methodist Meeting House, but it wasn’t for a lack of trying. The City of Hillsboro, Oregon, a suburb of Portland, hopes to construct a major road that would bring a rural area into industrial development. This project had it all: a project very high on Governor Kitzhaber’s economic development plan, a small unmarked pioneer cemetery that was thought to have Native American burials affiliated with the Nez Perce Tribe of eastern Oregon/western Idaho, and extensive negotiations surrounding how to discover or rediscover the anticipated archaeological remains, and a number of local residents concerned about the loss of historic resources. Media attention captured the high expectations of important discovery as remote sensing technologies were employed to identify hot spots where the missing meeting house foundations and associated burials might be located. The SHPO, Tribes, locals, historians all believed that there was something to be found out there. The City and State had to ‘do something’ to protect the resources expected out there. Permitting, meetings, stakeholder coordination and working in a media fish-bowl is a narrative of its own. The mystery remains but many lessons were learned along the way.

Sharon, Gonen (Prehistory Laboratory, Tel Hai College)

[26] Levallois in Acheulian Giant Cores?

The large flake Acheulian is a substantial stage within the Acheulian Techno-complex in which bifacial tools were shaped on large flake blanks detached from giant cores. While the end products of this
industry, primarily handaxes and cleavers, are astonishingly similar in shape and size world-wide, the core technology applied in their production is highly diverse. Recent research demonstrates that some of the Acheulian giant cores from very remote regions such as South Africa and India follow, at least in part, the definitions of the Levallois core method. The questions to be asked of these findings are: is the method really Levallois? Can this term apply to such large tool production or is the definition limited to small core sequences? What is the meaning of the similarity in tool shape and size versus the diversity in core technology? Most interestingly, are these highly inventive core technologies an example of convergent social evolution or is it simply a modification of a known technology for use in different conditions and with the rock types and shapes of varying regions?

Sharp, Kayeleigh (Southern Illinois University Carbondale) and Melissa Litschi (Southern Illinois University Carbondale)

[104] E-data and the Gallinazo: Exploring the Past in the Technological Present

Archaeologists working in international research settings face challenges of data accessibility, limited time frames, and optimizing data collection. The methods devised for our recent two-week field season were guided by two critical concerns: (1) given the ever-increasing difficulties of sample exportation from Peru, it was necessary to devise a rapid method of data collection that would preserve as much information as possible in the time allotted, and (2) determining future excavation locations required a custom method for data collection that would facilitate preliminary diagnostic analysis of artifacts without the physical sample. During the 2013 season, we successfully implemented and tested an innovative approach combining a digital image catalog, tablet PCs, and GIS for electronic data collection and e-transport of the sample. This approach proved highly successful in terms of data accuracy and portability. It was also useful for establishing criteria to be used in the discovery of differences between coexisting Gallinazo and Mochica technological identities as a part of our long-term research agenda. Preliminary results show that the tablets were useful for maintaining data integrity and provenience, and that the information contained in the electronic environment was easily transferred into the geodatabase structure for preliminary and future spatial analysis.

Sharp, Emily (Arizona State University) and Rebecca Bria (Vanderbilt University)

[105] Cycles of Violence and Cultures of War: An Analysis of Cranial Trauma in Recuay and Wari-Era Tombs at Hualcayán

Bioarchaeological investigations provide a deep time perspective on the causes and consequences of violent activities, and more specifically, they attest to the physical impact of violence on the body. This study investigates the association between cultural emphases on warfare and violence and the influence these developments have on cranial trauma rates. In the north-central Andes, the Recuay culture (A.D. 1-700) flourished during the Early Intermediate Period (EIP). While warfare is considered common for the Recuay era, this is one of the first in-depth studies of Recuay interpersonal conflict in the Ancash highlands. Excavations at the site of Hualcayán have uncovered human remains that date to the EIP and the subsequent time period—the Middle Horizon or Wari era. Approximately 80 crania from eight burial contexts, including above-ground and subterranean tombs, were analyzed to assess the frequency and patterning of antemortem and perimortem trauma. Osteological analyses reveal substantive evidence for violent conflicts, likely in the form of warfare and raiding. Individuals, specifically adult males, interred in Recuay tombs exhibit high rates of healed trauma. Other contexts show trauma on juvenile and adult female crania. Results indicate significant differences in trauma type and frequency across sex, age-at-death, time period, and burial location.

[251] Sacred Narratives of Cosmic Significance: The Place of the Keesee Figurine in the Mississippian Mythos

The recovery of flint-clay effigy pipes and sculptures of male figures from late prehistoric sites in the southeastern United States suggests that their distribution may represent the deliberate dissemination of important elements of sacred narratives, cultural practices, and religious rituals. Building on the scholarly efforts of James A. Brown, Thomas E. Emerson, and F. Kent Reilly, this presentation considers the contribution that the newly discovered Keesee Figurine from Phillips County, Arkansas, can make to our understanding of one or more of the sacred mythic narratives of the Mississippian world. This sculpture offers an important link between prehistoric images of supernatural figures and social, communal, and religious practices of the historic period.

Sharpe, Ashley (University of Florida)  
[113] Evidence of Preclassic Long-distance Trade at the Maya site of Ceibal, Guatemala  
Excavations over the past decade at the Maya site of Ceibal, Guatemala, have revealed new evidence of complex inter-regional interactions between the Gulf-region Olmec and southern Maya lowland civilizations, calling into question earlier arguments that the Olmec had been the “Mother Culture” or original source of cultural innovation in ancient Mesoamerica. In addition to architectural, artistic, and ritual similarities between the Preclassic (1000 B.C.-A.D. 100) Olmec and Ceibal Maya, there may also exist evidence of long-distance trade between the two regions in the form of marine resources, particularly shells. Here we present the preliminary results of the zooarchaeological material at Ceibal, assessing the type, source, context, and potential use of marine species at the site. We compare this information between Ceibal and contemporaneous Olmec sites, and discuss the potential for the long-distance trade of animal resources as a linking factor between these two regions.

[203] Personhood in Death, Personhood in Life?: Tiwanaku Infant Burials in the Moquegua Valley, Peru  
Large-scale excavation and analysis of Tiwanaku burials at Moquegua Valley sites including Chen Chen, Omo M10, Rio Muerto and Tumilaca la Chimba have been instrumental in illuminating provincial Tiwanaku burial practices through time. Allowing for subtle and limited variations, a standard set of funerary treatments that spans differences in cemetery, intra-community group, sex and age, is recognizable in Moquegua. Notably, cultural norms about how to treat the dead extended to the very youngest members of Tiwanaku towns in the valley. In Moquegua, Tiwanaku infants, neonates and miscarried fetuses were buried in community cemeteries and afforded the same mortuary treatments as their elders. This apparent inclusivity contrasts starkly with numerous cross-cultural archaeological, ethnographic and historical contexts, in which the relative absence of neonates and infants from cemeteries and their non-normative disposal is seen as evidence that the categories of person and human are often distinct, with personhood ascribed not at birth but during later rites of passage. Focusing on the funerary rites surrounding fetuses and babies in Moquegua and comparing them with other regions during the Middle Horizon, I consider the implications for our understandings of personhood in and beyond this Tiwanaku enclave.

[124] Discerning Changes in Dominican Land Use through GIS  
In this paper we examine the ways in which environment informs land use through different periods of occupation in Dominica, an island with nine active volcanoes and less that 8% flat land. The earliest papers on the archaeology of Dominica characterized the island as being unfavorable for intensive habitation and the terrain impenetrable for archaeological prospection. This paper reports on two long term projects undertaken in Dominica that contradict this view, one focused on the colonial period and one on the pre-Columbian period. Both projects utilize a variety of methods including remote sensing, GIS mapping, and extensive pedestrian surveys. A comparison of settlement patterns associated with industrial and subsistence agriculture show constructed patterns of land use are a critical factor in people’s daily lives and in broader patterns of community organization and interaction.

Sheets, Payson (University of Colorado)  
[194] The Ceren Village as a Compressed Rural Landscape  
Maya settlements ranged from isolated farming households through small and large villages to the large urban site of San Andres during the middle of the Classic Period in El Salvador’s Zapotitan valley. Before
it was buried by volcanic ash about A.D. 630, the Ceren village was much like dozens of other small
villages in the valley. Here the focus is comparing the isolated farming household to the advantages of a
score of households coalescing into a settlement. Each Ceren household overproduced something for
exchange with other households, thus avoiding the need to be largely self-sufficient economically. Each
household focused on producing an artifact or special plant material in amounts well beyond what they
would consume internally. Households were within a 5-minute walk of each other. Non-royal governance
was effective in organizing political, economic, social, and religious activities and the structures in which
they took place. Local individuals were responsible for construction and maintenance of the sacbe, and
they had considerable discretion in how they achieved their goals, within the parameters of cultural
acceptability. Compressing rural households into a village had disadvantages, including some loss of
privacy and increased concern with theft.

Sheldon, Craig and Ned Jenkins (Alabama Historical Commission)

The Hernando de Soto and Tristán de Luna Entradas and the Provinces of Talisi and Tascaluca
in Central Alabama.

Assemblages of 16th century Spanish artifacts in collections from four aboriginal sites in central Alabama
are traced to the expeditions of Hernando DeSoto and Tristán DeLuna. Most of the artifacts are mortuary
associations suggesting that they came from direct Indian-Spanish contact. Analysis indicates potential
useful distinctions between some of the artifacts of the DeSoto and DeLuna expeditions. Two of the sites
are identified as Talisi and Atahachi, principal towns visited by DeSoto in 1540. Another site is probably
the Atache described by DeLuna in 1559/1540. Each of the provinces had distinctive geographic ceramic
phases and components, which greatly assists in our interpretation of chiefdom organization in the region
and of changes in pre and post DeSoto and DeLuna settlement patterns, mound construction, display
items and other aspects of culture.

Hunts in the Ancient Roman Colosseum

The aim is to investigate spectacles in the Colosseum at which animals were killed by professionals
called "hunters." These spectacles demonstrated human triumph over the natural world, but also the
supremacy of the Roman state over distant lands. They had roots in rural events which confirmed the
ability of humans to create a secure environment for themselves. First, at annual festivals farmers
celebrated the community's success in producing food by killing animals that preyed on livestock or
consumed food plants. Second, wealthy statesmen promoted notions that aristocratic hunts on their
private estates made a man better fit for public service and helped the community by eradicating
dangerous and devouring animals. Politicians vying for urban votes brought the hunting experience to
town in the form of staged hunts. These permitted town-dwellers to take part, at least as spectators, in an
activity otherwise beyond their means. As the Romans expanded their territory, they imported species
from the most remote areas of their empire: lions from Asia Minor, elephants from Africa. Their
destruction in front of the Roman people provided concrete proof that Rome was able to subdue any force
that resisted it.

Shennan, Stephen

Demography and the Cultural Evolution of Neolithic Europe

This introductory paper will provide the background to the session. It proposes that the key basic
dimension of cultural systems is population, so the reconstruction of demographic patterns is
fundamental. Changes in population size and density are linked to economic patterns so it is necessary to
analyse the factors that affect them. In turn population patterns impact cultural patterns and processes. A
novel treatment of summed calibrated radiocarbon dates shows that the introduction of farming to Europe
was followed by a boom-and-bust pattern in the density of regional populations, not the steady population
growth to a ceiling usually assumed. Demographic patterns for 24 different regions of Central and Northwest Europe 8,000-4,000 cal. BP will be presented and it will be shown that the patterns do not appear to be related to climatic factors. Possible alternatives will be discussed.

[152] Approaching Sustainable Public Archaeology on Rapa Nui (Easter Island, Chile): Education, Conservation, Research, and Tourism

Rapa Nui, like many other locations rich with archaeological heritage, poses extreme risks and potential when attempting to combine cultural conservation with tourism. After ten years of work on Easter Island, Terevaka.net Archaeological Outreach (TAO) has developed a program to provide tourists, hotels, archaeologists, and conservationists with a vested interested in the education of high school students local to the island. Our 2013 project sheds light on both a recipe for success in sustainable archaeology on the island and our shortcomings in reaching the goals of all participating organizations.

Shephard, Christopher (College of William and Mary) and Martin Gallivan (College of William and Mary)

[338] Powhatan Sovereignty and Consumer Politics in the Algonquian Chesapeake

Powhatan sovereignty was structured around the acquisition and socialization of "foreign" materials. In the centuries preceding the arrival of Europeans, shell beads and copper-dangerous and unpredictable objects-were introduced into the Virginia Algonquian world from sources beyond the Chesapeake by priests and chiefs. Typically stored away from settled areas, these objects were intermittently brought into circulation during feasting and commemorative events that mediated relations of authorization and subjection. As outsiders, Europeans and the objects that they possessed represented a danger that also needed to be socialized. In the well-known divination of John Smith, for example, priests performed a ceremony aimed at indigenizing Smith and his compatriots, making them no longer tassantasses (strangers) but Powhatans and subjects of the paramount chief. In this paper we explore the historical processes that structured sovereign relations in the indigenous Chesapeake and the changing materiality and consumption of objects that occurred as a result. The seizure of Virginia Algonquian lands during the colonial era influenced new forms of sovereignty. The desire for objects that mitigated the destructive power of other-worldly beings continued in the Powhatan world, though guns and swords became the primary means for chiefly authorities to maintain land and to protect populations.

[190] "After the Conquest": The Archaeology of Colonial Honduras

Archaeological research in Honduras is predominantly concerned with the period before European colonization. This has contributed to an impression of discontinuity between the late prehispanic period peoples of Honduras and the histories that came after colonization. In this presentation, I reconsider what has been accomplished through excavation and research on archival documents. I point to a number of challenges for creating archaeological understanding of colonial Honduras. There is a major disconnect between the way archaeologists working even on the late prehispanic period conceptualize the units of analysis (usually, as linguistic/ethnic units with a wide geographic distribution) and how the same people were described in the first generations of colonization. It has been challenging to assign dates to colonial sites and assemblages because the default assumption has been that colonial period sites will yield European tradition materials, whereas these are rarely found in Honduran sites. There are contradictions between descriptions in documents, which describe a rich material world, and those few colonial sites that have been explored, in part due to retention of objects as property transmitted to successors. I end by demonstrating that these problems can be avoided and rich archaeological understandings of the colonial period can be generated.

Shimek, Rachael (University of Wyoming) [132] What Does a Dog Cost? Factors Related to Domestic Dog Husbandry and a Cost-Benefit Analysis of Dogs as Hunting Aides

Domestic dogs are frequently associated with human populations throughout the world beginning in the Upper Paleolithic, but their physical remains are few and far between in the archaeological record. Therefore, archaeologists pursuing the subject of human-dog interactions in prehistory must utilize other sources of information to help generate an understanding of dog husbandry. This paper uses historic and contemporary ethnographic data regarding dog use among hunter-gatherer groups to examine some of the anthropological and ecological factors associated with dog husbandry. Anthropological factors such as average annual mobility and ecological factors such as environmental productivity are expected to condition and constrain how domestic dogs are utilized by humans. A more detailed examination of the use of dogs as hunting aides is explored from a behavioral ecology perspective. A theoretical optimality model of the costs and benefits of using dogs to hunt helps generate expectations for dog use both in the present and in the past. Such alternative paths to the anthropological study of human-dog interactions are complimentary to traditional archaeological methods reliant on the recovery and analysis of canid skeletal material.

Shiratori, Yuko (The Graduate Center, CUNY), Carolyn Freiwald (The University of Mississippi) and Timothy Pugh (Queens College, CUNY) [147] Postclassic and Contact Era Animal Use in Itza Maya Households at Tayasal

The Petén Lakes region in Guatemala was occupied by distinct Maya ethnic groups during the Postclassic period (A.D. 1200-1500), and use of animal resources varied in each community. We present basic patterns of faunal use in subsistence and ritual contexts in Itza households at Tayasal, and compare them to similar contexts in households at the Kowoj capital of Zacpeten. Use of animals from different catchments - local vs. non-local, lacustrine vs. terrestrial - and distinct domestic and wild species may reflect one way of expressing group identity, or even social distinctiveness. More broadly, ethnographic analogy, ethnohistoric sources, and the frequency and distribution of different taxa provide insight into the social and economic organization of the Itza Maya from the Postclassic through the Contact periods at Tayasal.

Shoberg, Marilyn (GSAR) [318] Microwear Analysis of Stone Tools from Clovis and Older-than-Clovis Cultural Occupations at the Gault Site

Microwear analysis of stone tools from Clovis and Older-Than-Clovis occupation levels at the Gault Site provides evidence of a broad spectrum of cultural activities during both of these early occupations. Tools were used for hunting and butchering animals, and for gathering and processing plant materials. Other artifacts were manufactured from animal skins, wood, reed, and bone. Utilized tool forms include projectile points, large bifaces, prismatic blades, gravers, scrapers and modified flakes.

Shock, Myrtle [246] Resource Management in the Amazon: A View from Macrobotanical Remains

A survey of macrobotanical remains in Amazonian occupations is ongoing to investigate Pre-Columbian
resource management strategies. Locations across the Brazilian Amazon with active archaeological research projects have been investigated to distinguish contexts with preservation of charred remains. Sites date to the last two millennium and are notable for Terra Preta, a fertile anthropic soil generally associated with sedentary occupations and concentrations of ceramics. Analysis of plant remains seeks to understand foraging and farming practices in a region where agroforestry is a viable subsistence alternative. A notable, recurrent species in archaeological remains is the Brasil nut (Bertholletia excelsa) for which the modern tree distribution in groves may be the result ancient management practices.

[172] *Geophysical Investigations Meters Deep: Examination of the Johnston Site (36IN002), Indiana County, Pennsylvania*

The Johnston site (36IN002), located near the Conemaugh River in Indiana County, Pennsylvania, is a Monongahela village dating to the Johnston Phase (1450-1590) that is buried beneath a meter of alluvium soil. Excavations at Johnston began during the 1950s and resumed in the early 2000s by Indiana University of Pennsylvania (IUP). Much of the research done by IUP has focused on the location of stockades at the site. While three stockades have been discovered at the Johnston site, no research has attempted to locate features inside the stockade. Geophysical investigation using ground penetrating radar (GPR) and electrical resistivity at the Johnston site was undertaken in the fall of 2013 to examine the possibility of anomalies within the stockade. This poster summarizes the results of these investigations.

[337] *Airborne LiDAR: Optimizing the Technique for Archaeological Research in Mesoamerica*

Geodetic images (e.g., shaded relief, 3-D perspective, and color coded relief images) produced from airborne laser scanning (ALS), a.k.a. airborne light detection and ranging (LiDAR) observations are often stunning to the eyes of laypersons and scientists alike, especially when they reveal the surface features normally hidden by dense vegetation. Such images enable researchers to view landscapes at scales and resolutions never before possible, revealing natural features such as fault lines and surface erosion in intricate detail, along with such anthropogenic features as roadways, agricultural terraces, irrigation networks, and buildings, or their ruins. The information and insights derived from ALS observations have proven transformative to research in geomorphology and geophysics during the past decade, and because archaeologists share the need for similar information about landscapes, ALS may well have similar impacts on archaeological research, particularly in rainforest covered areas of Mesoamerica. ALS observations have already been used to find hundreds of additional features at known sites, and to find previously unknown sites, in Belize, Honduras, and Mexico, and the results of these early projects are being studied to find ways to improve the techniques that will be used in future archaeological projects.

Prehistoric Obsidian Use in the Truckee Meadows and its Implications for Settlement Patterns along the Sierran Front

Relationships between mobility and technological organization have been important topics in archaeology, especially in the Great Basin. The Great Basin is dominated by open air lithic scatters lacking in subsistence residues, features, and architectural remains making mobility and settlement pattern reconstruction more difficult. Using data from previous collections, reports, and my own testing, I explored obsidian patterns within the Truckee Meadows region. My research focused on two major issues: (1) testing the implications of Delacorte's (1997) model, which implies that the Truckee Meadows was part of a more extended settlement system earlier in time and a localized system later in time; (2) the ability to generate radiocarbon-hydration pairs for Sutro Springs obsidian to further our understanding of the first research question. Although my results failed to provide insight on absolute dating from radiocarbon-hydration pairs, a new obsidian pattern was identified during the Late Archaic Component for the Truckee Meadows area.

Siegel, Peter [250]
Island Historical Ecology: Socionatural Landscapes across the Caribbean Sea

Humans leave traces of their actions on landscapes in subtle and dramatic ways. First-colonizers to new places are often difficult to identify archaeologically because of the light imprint of their activities and issues of preservational bias. Understanding colonization history and subsequent developments in the Caribbean has been confounded by these problems. We address Caribbean colonization history through an aggressive data-intensive project in historical ecology. Wetlands on selected islands between Venezuela and Puerto Rico were cored to obtain microfossil and pedological data to investigate Caribbean island ecologies from the perspective of social and cultural interventions over the full range of human occupations. Through the analysis of multiple proxies, we demonstrated that the Lesser Antilles were colonized and landscapes modified during the Archaic age, considerably earlier than what many archaeologists heretofore believed. Over the ensuing millennia, subsequent people continued to manage increasingly modified landscapes. On some islands, we obtained data dramatically illustrating the effects of early European colonial occupations, especially in the context of sugarcane plantation agriculture. This chronologically and geographically extensive dataset provides us with an unique empirically based perspective on the Caribbean islands as socionatural landscapes.

When the Foreign Becomes the Familiar: Consumption Practices on Native American Reservations in New England

A significant element in studies of Native American responses to colonialism is the notion of “adoption.” Although this concept works in terms of the first introductions of the foreign into the familiar, particularly with respect to material culture, it cannot be sustained as an interpretation and frequently cannot even work in the first instance if the archaeological sites being studied do not represent actual adoption. More frequently, Native American archaeological sites during colonial eras manifest acts of ongoing consumption, and these require different analytical perspectives to account for the process of familiarizing the foreign, the actual definition of “the foreign” itself in archaeology and lived experience, and the position of such objects in individual experiences and collective memories. These processes have been studied for ten years now on the Eastern Pequot reservation (established 1683) in southeastern Connecticut as part of a long-term collaborative field school, and this paper uses that research context to examine the nature of consumption and colonialism on reservation households in Native New England and considers the implications for broader North American colonial contexts.

Salt: Mover and Shaker in Ancient Maya Society

As a basic biological resource in short supply at inland urban cities where the Classic Maya civilization developed, the coastal production and transportation of salt accorded the maritime Maya a degree of political and economic autonomy. The methods of salt production reflect the maritime landscape: the arid northern Maya lowlands were suitable for solar evaporation of salt along the Yucatan coast. Heating brine in pots over fires was more effective in the wetter climate farther south, especially along the coast of Belize. The production of salt in wooden buildings at the Paynes Creek salt works, underwater sites submerged by sea-level rise that provided stunning preservation of wooden architecture, offers a model for salt production elsewhere along the coasts of Belize and Guatemala. Changes in salt production and trade from the Preclassic through the Classic and Postclassic periods are evaluated, along with examples of production at inland salt springs.

Archaeological Sites, Natural Processes, Anthropic Activity and Conservation of the Central Plateau of Brazil

This work determines the correlation between certain events noted in the archaeological area of Serranópolis, namely natural processes, anthropization and conservationist initiatives. The correlation suggests growing impact in this archaeological area, both in the already registered sites and the potential identification of new sites occasioning a hiatus in the archaeological context. This correlation also indicates that conservationist initiatives, when bounded without technical criteria, in areas where archaeological sites have been detected, may retard or accelerate the natural and anthropic impact on the cultural heritage.

Silva, Jorge [281]

Spatial Functionality and Ritual Offerings in Lurín Valley Ychma Households

This work will make public recent findings from the excavations of the 2013 Season at the domestic sector of Panquilma, Peru, especially those from unit 09. It will attempt to identify the main characteristics of a typical household of the Ychma culture. It will also interpret the evidence recovered to propose a spatial functionality for each component of this household and its sequence of occupation. Special attention will be paid to offerings found in the unit so as to correlate different types of offerings and their characteristics to the spatial functionality of household components in this Lurín Valley site.

Silva De La Mora, Flavio

How Were They Getting Around? Looking at Communication and Exchange Routes in the Northwestern Maya Lowlands during the Classic Maya: A Study in the Palenque-Chinikihá Region

The essence of how exchange, movement of people, and goods was organized in Pre-Columbian times is poorly understood, yet exchange and the movement of commodities is believed to be a critical aspect in the establishment and development of sociopolitical relations in Mesoamerica. Previous studies in Maya archaeology have seen a tendency to interpret ancient economies under two basic models, as either a centralized prestige goods model or a decentralized subsistence goods model. The Northwestern Maya Lowlands has been an important part of archaeological inquiry and resent studies in the Palenque-Chinikihá region provide a case study of the larger regional dynamics that united and separated the local communities during the Classic period. Using sourcing analyses on obsidian tools and debitage, united with the previous investigations this presentation will delve into the regional settlement distribution, communication routes and exchange of goods in the Palenque-Chinikihá region.

Portable X-Ray Fluorescence Analysis of Paints From Prehistoric and Historic Period Native American Rock Art Sites in Southern Illinois

Over the past several years, we have initiated a research program using non-invasive portable X-ray fluorescence (pXRF) to analyze the elemental composition of manufactured pigments used to produce prehistoric pictographs from numerous sites in southern Illinois spanning the period AD 1000-1835. In this paper we present the results of our analyses as they relate to variability in prehistoric paint production and use and possible links between rock art sites, design motifs, and cultural identities in southern Illinois over a period of almost 1,000 years from the Mississippian to historic periods.

The “Ambassadors to the Past” Program on Ambergris Caye, Belize: Embracing an Archaeology for, with, and by Indigenous People

In the past decade indigenous peoples of the Americas have become increasingly involved in various aspects of archaeological research, and the development of ‘indigenous archaeology’ has taken many forms. This paper describes some of the ways that indigenous peoples of Belize have been active participants in both archaeological fieldwork and public outreach efforts in San Pedro, Ambergris Caye. As part of the ongoing “Ambassadors to the Past” program Mopan and Kekchi Maya university students have been teaching short classes on archaeology in San Pedro’s secondary schools over the past two years. The program is aimed at helping Belizean students make connections to their country’s ancient Maya heritage. The successes of the program are discussed along with the challenges the ‘ambassadors’ have faced in helping secondary school students make meaningful connections to their cultural heritage. The unique perspectives and approaches these Maya university students bring to a public archaeology program specifically aimed at indigenous peoples are examined. Finally, the roles indigenous people play as major stakeholders in illuminating their own history are considered.

Simmons, Alan (University of Nevada Las Vegas, Department of Anth)

A View from the Top: Ais Giorkis, an Early Cypriot Neolithic Village in the Uplands

Ais Giorkis is amongst a handful of early Neolithic sites on the Mediterranean island of Cyprus that have re-written our conception of Cypriot and Near Eastern prehistory and have contributed to understanding how islands are colonized. Sites belonging to the “Cypro-PPNB” are unexpectedly early (ca. 7500-8400 cal. B.C.) and are contemporary with developments on the mainland. Ais Giorkis is one of these sites, and the only excavated one that is located in the foothills; the preferred location for settlement appears to be coastal. Ais Giorkis is unusual not only for its location, but also its rich artifactual, structural, and economic materials. These include imported obsidian, a technologically refined blade technology (including refitable cores), abundant ornamentation, well-preserved paleobotanical materials that include some of the earliest directly dated domesticates in the Near East, and the second largest faunal assemblage on the island, which include small amounts of cattle, previously thought to be absent from the island until the Bronze Age. In addition, unusual oval platform structures and deep pits are present. The results of ongoing interdisciplinary investigations at Ais Giorkis are summarized here and put into a broader context.

Prospecting Epigraphical Landscapes: The Use of Traditional Geospatial-scale Tools in Analysis of Sub-millimeter Resolution 3D Data

With recent advances in technology, archaeologists have gained greater access to a wider variety of scales and resolutions in remotely sensed data. While many of these advancements were developed for other disciplines, their archaeological applications are made possible through innovative methodologies moving beyond their initially intended purposes. This paper aims to assess the potential utility of employing software and methods intended for landscape-scale to process and analyze sub-millimeter 3D scan data of the ancient inscription of Drakon’s Law on Homicide, one of the most important documents in the history of criminal law in ancient Greece. Unfortunately, its worn and degraded surface renders much of the inscription illegible. A joint team from the American School of Classical Studies at Athens and the Center for Advanced Spatial Technologies (CAST) were the first to be granted permission to study this inscription since 1969 and conducted close-range 3D scanning. While the effort yielded some promising results using 3D scan software for analysis, this paper will discuss the innovative use of 2½D GIS and airborne lidar software tools to explore additional means of deciphering new letters in the 3D scan data and gain further knowledge of what was written in Drakon’s law on homicide.

Competition and Conflict: A Reassessment of the Role of Warfare among Salado Platform Mound Communities in Central Arizona

The occurrence of prehistoric warfare in central Arizona has been a topic of much discussion in recent decades, but to advance our anthropological understanding of the role of societal conflict it is essential to contextualize the role of warfare based on theoretical and ethnographic perspectives as well as multiple lines of archaeological evidence. This research focuses on the Salado platform mound communities of the Tonto Basin in central Arizona and surrounding region during the period of A.D. 1250–1450, a time of regional population movements and aggregation. Extensive data available from the Roosevelt Archaeology Projects and other excavations in the study area are synthesized and evaluated. In addition to physical evidence of violence, the social networks within the study area are assessed based on comparative study of the archaeological collections. Results are used to evaluate alliances and competition among the platform mound communities where conflict may have occurred on individualized or internecine levels, or with external groups. Theoretical and anthropological perspectives regarding the motivations and mechanisms of warfare inform our approach to assessing evidence of conflict in the archaeological record and of attaining more complete and informed explanations of the role of conflict in prehistoric Salado society in central Arizona.

Norse Greenland Homefields as Narratives of Resilience, Collapse and Survival.

Homefields, the managed areas of land immediately around farm dwellings and often enclosed with turf and stone boundary walls, are ubiquitous features of Norse North Atlantic agricultural systems. In this paper we offer a regional radiocarbon and optically stimulated luminescence (OSL) chrono-stratigraphic framework for Norse homefields in the Easter settlement of Greenland, crossing the Viking Age to Medieval transition and ranging from inner to outer fjord locations. We go on to demonstrate that complex soil and sedimentary field- and micro- stratigraphies are associated with these homefields. These retain important records of environmental change, evidenced by contrasting phases of eroded soils and peat accumulation, and management adaptation, evidenced by soil amendments, nutrient levels and controls on soil water. Regional assessments of these soil and sedimentary records indicate varying types and intensities of environmental change faced by Norse Greenland communities and that resilience to these changes depended on a diversity of homefield management strategies specific to the environmental problems faced and contrasted with location, size and nature of the farm.

Electrical Resistance Survey of Historic Cemeteries: The Pro and Cons of the Technique

The survey of historic cemeteries has proven to be one of the more difficult archaeological site types to investigate using geophysical techniques: a conundrum for researchers given the size and obvious patterning of graves contained within the majority of cemeteries investigated. AMEC has used electrical resistance as an investigative technique at over 35 cemeteries across North America in a variety of environmental and soil conditions. These surveys have provided a wealth of insights to effectiveness of the technique based on an array of changing conditions, such as soil moisture, particle size, age of interment, and spacing between graves. These insights are explored within this presentation, as well as the pro and cons of the technique for the survey of historic cemeteries.

Simpson, Erik (Salmon Ruin - Division of Conservation Archaeology)

Identity and Ethnogenesis in the American Southwest

The role of identity and ethnicity has become an important component in an increasingly nuanced discussion of social interaction and organization. In the northern portions of the American southwest, the evolving identity of populations in the upper San Juan region of the early A.D. 700s to the late A.D. 1200s is interrelated with, but distinctive from, neighboring populations. As such they provide a contrasting view of the sweeping and far reaching social and cultural changes of the period. This peripheral yet long-lived
process of identity formation and maintenance develops in opposition to Early Pueblo Period developments occurring to the west and culminates in the dramatically homogenizing Gallina ethnogenesis.

Sims, Marsha (Nat Resources Conserv Svc)  
[166] Extinctions of Fauna in North America, A Focus on Quartzipsamments and Human-Fauna Symbiotic Relationship  
Quartzipsamments, wind-blown sandy soils high in quartz of the Entisols, developed across the world in the late Pleistocene. Previously, glacial tills and river deltas provided this type of soil. Both human remains and remains of Pleistocene fauna are recovered predominantly in areas shown as Quartzipsamments. The reasons are coincidence, high preservation in these areas, need for the same minerals by certain Pleistocene fauna, predictable areas to locate fauna, and others not listed. This research studies soil samples from three faunal sites and overlays of maps showing high correlation to Quartzipsamments for Pleistocene fauna and humans. Various factors lend credence to selection of Quartzipsamments for dietary benefit over the other choices. This paper stresses trophic levels and the symbiotic relationship of humans with fauna in North America as the driving force for extinctions. Auerbach (2012) shows wide bodies and high body mass of Paleoindians is indicative of high-latitude, arctic region, or cold-environment adaptations. As the world warmed, these humans expanded their range just as Pleistocene fauna. Quartzipsamments allowed this expansion into areas that support varied vegetation and following the fauna that left dung heaps fertilizing seeds increased the food availability and carrying capacity of humans who out completed the fauna.

Sims, Christopher  
[278] Applications of Geospatial Analysis and a Landscape Approach to Paleolithic Sites in Portugal  
Developments in the domain of landscape approaches to archaeological research have been greatly advanced by the use of geospatial technologies. Despite the boon to theory, methodology, and technology, certain questions remain where the spatial distributions of archaeological material are complicated by other factors. Geomorphic processes significantly hinder site survivability and fieldwork. Such is the case for Paleolithic archaeological sites in Portugal, where the current landscape bears little to no resemblance to environmental conditions during the Pleistocene. Therefore, approaches using landscape theory and geospatial technology must be adapted, and a reworking of conceptual frameworks regarding site distribution is necessary in order to understand locality patterns. This presentation focuses on the results of geospatial analysis of data from recent archaeological investigations in the coastal and Estremadura regions of Portugal, and places them within a conceptual framework that allows for severe environmental changes and limited site survivability.

Sims, Ashleigh (College of Wooster) and P. Nick Kardulias (College of Wooster) [300]  
A Study of National and Local Identity at the Modern Cemetery in Athienou, Cyprus  
The current study examines a modern cemetery in the village of Athienou on the island of Cyprus. This cemetery is unique because the town is very close to the border between the Republic of Cyprus and the Turkish Republic of Northern Cyprus. An analysis of the cemetery is undertaken using a combination of landscape archaeology, following Ashmore and Knapp (1999), and Saxe’s (1970) hypotheses on mortuary analysis. Data resulting from a preliminary study conducted there in 2005 are used to show how the cemetery has evolved over the past eight years. Current analysis demonstrates how the cemetery, through the attributes of the gravestones and the overall layout, exemplifies the cultural identity of the people interred there. By prominently displaying members of certain corporate groups, such as war veterans, the cemetery is used to legitimate the people of Athienou’s claim to the surrounding land. The theoretical framework adopted here is applicable to the study of archaeological cemeteries both in other parts of the Greek-speaking world and other regions. Additionally, it enhances our understanding of the cultural identity, social structure, and status of corporate groups in a given society.

Sinclair, Paul (Uppsala University), Paul Lane (Uppsala University) and Anneli Ekblom (Uppsala University)  
We report on recent work on the historical ecology of eastern and southern Africa. Long term trends in settlement aggregation and resource utilization are analyzed from a multi-scalar regional and landscape perspective. In this study, urbanism on the Zimbabwe plateau is viewed in terms of deep time interactions between ideology and governance, networks of local and interregional trade, systems of resource
procurement and responses to climate change. Our second study explores rural landscape dynamics and social transformations in the Lower Limpopo Valley and specifically present day conservation management in Kruger National Park. In both of these, long term trends in settlement aggregation and resource utilization are evident in selected areas of eastern and southern Africa. Implications of the research results for sustainable futures are compared. Finally, we report on new work on the nineteenth century ivory trade and its antecedents, and how some of the newly emergent data challenges dominant environmental narratives concerning the drivers of soil erosion and agricultural intensification, which in turn have tended to shape modern day interventions in local livelihood strategies in the name of ‘development’. This latter case study illustrates the potential contributions of historical ecology to more ‘social’ archaeological interpretations and the analytical potential of multi-sited archaeology.

Archaeology in Museums: Finding the Forgotten
This paper will explore the role museums play in the exploration of Mississippian cultural and iconographic representations—principally through the care and collection of artifacts, and facilitation of object-based research. Moreover, this paper will explore the depth of research that can still be conducted on museum collections, either through the accumulation of multiple assemblages from various collectors through purchase or donation, or via collections from old archaeological excavations. Specific examples of the research potential of museum collections emphasized in this paper include objects from the Gilcrease Museum in Tulsa, Oklahoma, with particular emphasis on a Hopewell Period bone scepter, textiles and basketry from the Spiro mounds, and fragmented engraved shell.

Ecological Modeling of Middle and Upper Paleolithic Sites in the Vezere Valley, France
This project compares the ecological setting of Middle and Upper Paleolithic sites from the Middle Vézère region of southwestern France. This region works well for this type of study because of its diverse environmental character, well understood chronology and dense archaeological record. The spatial location and chrono-cultural attribution of nearly 100 sites across the region were included in a database of relevant geological data and modern ecological characters, including measures of diversity and proximity to important resources. Within a GIS framework, these disparate data were then incorporated into models of important patterning between the Middle (Neanderthal) and Upper (Homo sapiens) Paleolithic populations of the region. Using tools from ecological niche modeling that rely on presence-only data (including MaxEnt), this project demonstrates a clear difference in the variability of environments exploited by these two groups, but also gives insight into important controls on settlement between the two time periods. It suggests a preference for more heterogeneous environments during the Middle Paleolithic, and a focus on particular resources during the early Upper Paleolithic. The analytical techniques employed here have clear application for other archaeological projects and a brief discussion of their utility will be included.

Building on Ancient Ground: Excavations at a Formative Period Mound and Sunken Court Complex in the Northern Lake Titicaca Basin
This poster presents the results from the 2013 excavations at Huayra Mocco, a Formative Period (ca. 1300 B.C.-A.D. 100) sunken court site associated with the greater Taraco complex situated in the northern Lake Titicaca Basin of Peru. We examine the construction techniques of architectural features uncovered in Unit III, located on the northwest slopes of the mound. These features include a large, Formative Period terrace face and associated canal. Evidence from lower strata suggests that the Formative Period architectural features may have been constructed directly on top of and even cutting into Archaic Period deposits. In light of these findings we propose two possible interpretations: (1) The lower strata represent terminal Archaic deposits and Huayra Mocco served as one of the few continuously occupied sites during the Archaic-Formative transition in the altiplano; (2) Huayra Mocco was selected as the site for Formative monumental architecture because of its substantial Archaic
occupation. Through exploring these hypotheses we aim to demonstrate the possibility of unprecedented long-term site occupation and re-occupation in the northern Titicaca Basin.

A Multi-Methodological Approach to the Detection of Graves

Geophysical remote sensing, a method often employed to noninvasively detect the presence of archaeological features, has been successful in the detection of human burials (De Vore, 2007; De Vore and Nickel, 2003; Jones, 2008). However, the success of geophysical techniques in the detection of human burials is dependent upon multiple factors: methodology, vertical survey depth, terrain, soil chemistry, hazards, data processing, and grave conditions to name a few. The study presented here summarizes a systematic survey of major archaeological and geophysical journal reports on human burial remote sensing studies to further evaluate the effectiveness of geophysical prospecting for burial identification. As a result of field investigations, numerous (n=22) geophysical anomalies were identified and are believed to be those associated with unmarked graves. By employing multiple geophysical techniques archaeologists were not only able to assess which techniques detected the same anomaly, but also whether different techniques can identify different burial types.

Cusqueños, Huareños, and the Wari: An Evaluation of Intense Cultural Exchange in the Middle Horizon Cusco Region of Peru

This paper applies Green and Costion’s model of cross-cultural interaction to the Wari colonial setting in the Cusco region, exploring relationships that the Wari established with peoples of this region and others in the southern Andes from approximately A.D. 600-1000. It reviews past research on Wari/Cusqueño interaction before presenting new data from the Huaro Valley, where excavation at Hatun Cotuyoc, a residential sector of settlement, has revealed houses and mortuary remains pertinent to this inquiry. Evidence for interchange between Wari and Cusqueño populations is somewhat less intensive than expected at Hatun Cotuyoc, and possible reasons for this are addressed.

Reconstructing Paleo-environments and Seasonality of Occupation through Isotopic and Trace Element Analyses at Boodie Cave, Barrow Island, Western Australia

To complement and support the Barrow Island Archaeological Project investigating the nature of early occupation on the coastal landscape of northwest Australia, this presentation outlines an approach based on the isotopic and trace element analyses of the bone (including mammalian teeth and fish otoliths) and shell assemblages excavated from dated cultural deposits within Boodie Cave (Site J08-00) to reconstruct the changing palaeoenvironment and investigate the seasonality of site occupation. In particular, the relevant theoretical frameworks, methodological complexities, procedural practicalities, ethical questions, and environmental contexts will be reviewed to argue that the proposed research presents a significant and unique opportunity to critically evaluate the relationships between humans and the dynamic climatic conditions (including the intense variability in sea levels and aridity) experienced from the earliest occupation of Barrow Island in the Pleistocene (<45,000 years ago) to its termination in the early Holocene (7,400 years ago). It is suggested that the proposed research will confirm an interpretation of prehistoric coastal communities as highly adaptive strategists responding both reactively and proactively to the dramatic transformation of climate and resource availability over substantial time depth as well as across shorter-term seasonal changes resulting from monsoonal weather patterns.

A New Look at Old Faces in Maya Caves

Representations of simple anthropomorphic faces have been documented in caves throughout the Maya region. Earlier interpretations suggested that these signs were unrelated to elite graphic communication styles and were likely the work of peasants. Current interpretations, however, are shifting. Drawing from various sources including ongoing investigations at the cave site of Aktun Kuruxtun, Yucatan, I argue that these seemingly simple faces are closely connected to royal Maya graphic forms and that they served as synecdochic humanoid embodiments of ch’ulel or the life force believed by Maya people to animate the cosmos.

They Don’t Make Them Like They Used To: Point Production and Maintenance at the Middle Stone Age Site of Marmonet Drift, Kenya

The Marmonet Drift archaeological site in Kenya’s Central Rift Valley has a stratified sequence of over 26 meters of paleosols containing six Middle Stone Age archaeological horizons and thirteen volcanic ashes. Four volcanic layers have radiogenic argon dates ranging from 244 to 94 thousand years ago (ka). Excavation in 2013 recovered almost 8000 in-situ obsidian artifacts from two archaeological horizons: one lies directly above an ash dated to 94 ka and another directly above an ash with dates of 100 and 105 ka. The younger horizon is dominated by extremely thin unifacial and parti-bifacial points and knives. The older horizon has bifacial knives, large end scrapers and burins, but no points. Both assemblages contain high percentages of thin shaping and resharpening flakes with lipped platforms, very low external platform angles and radial scar patterns on dorsal surfaces, indicating invasive soft hammer flaking of large thin flake tools. These assemblages provide new evidence for the organization of technology, specifically in relation to tool production, shaping, maintenance and discard. They expand the known range of lithic technology variation in the East African MSA, and have important implications for our understanding of role of technological organization in the evolution of Homo sapiens behavior.

The Southern Nevada Public Land Management Act: Recent Archaeological Achievements

The Southern Nevada Public Lands Management Act, or SNPLMA, provided funding for archaeological research and outreach in southern Nevada. These projects included research on extant collections, cultural resource survey/inventory, site documentation and eligibility determinations, artifact and archive curation, and public outreach. This poster, by the Cultural Resource Team of the Southern Nevada Agency Partnership (SNAP), is a brief overview of the larger projects and programs that benefited from SNPLMA. In sum, this work significantly advanced the archaeological knowledge and awareness of Southern Nevada’s diverse resources, created a site steward program and partnership with the State Historic Preservation Office, and furthered public outreach efforts within the region.

Sload, Rebecca [33]

The Cave under the Sun Pyramid at Teotihuacan as a Chicomoztoc

Chicomoztoc, literally, “seven caves,” is the legendary ancestral home of the Aztecs, with each cave representing a different Nahua group. The concept fits within the framework of ancient Mesoamerican grand mythic traditions that also includes Tollan (“place of reeds”), Coatpecc (“serpent hill”), Tonacatepetl (“sustenance mountain”), and Altepetl (“water mountain”). Each of these, including Chicomoztoc, is accepted as having a more general and long-lived meaning than the Conquest period attribution. Chicomoztoc is interpreted as the place of emergence or cave of creation. Brady’s work with artificial caves, the spatial relationships of natural and artificial caves to surface architecture, the philosophy of religion, and ethnographic data produces the hypothesis that caves combined with mountains/pyramids and water define the Center, of which one aspect is Chicomoztoc. He agrees with Doris Heyden that the cave under the Sun Pyramid at Teotihuacan may be a Chicomoztoc. Up until now most support for the idea has been cross-cultural, relying on Conquest period sources of Aztec mythology about Teotihuacan. This paper uses 1978 Teotihuacan Mapping Project excavation data from the cave under the Sun Pyramid to explore the idea that the cave was a Chicomoztoc.
Small, David (Lehigh University)
[214] Using the Mortuary Record to Spot Phase Transitions
Complexity theory in its evolutionary frame is currently enjoying increasing usage by archaeologists who
view concepts such as self organization, chaos, and phase transitions more amenable to explaining the
record of the past than past theoretical frames. Several scholars have identified what they would label as
phase transitions in the archaeological record. One of the problems with this however, is that the results
of a phase transition may well be identified, but understanding the dynamics of that transition is yet to be
realized. I propose that using the mortuary record can be of great help in further elucidating this issue.
The period right before the phase transition, the "edge of chaos" was most likely a time of social fluidity
and uncertainty as new social structure was emerging. This period can be compared to that of
transegalitarian communities which were moving from one social structure to another. In transegalitarian
societies elaborate funeral feasting was used by aggrandizers to secure positions of strength and to
move toward creating new emergent institutions. In this paper I shall focus on identified periods and
cultures which underwent phase transitions, and locate the period of chaos before that transition through
mortuary analysis.

[77] Preservation Methods Go High-Tech through 3D Scanning
We are constantly looking for ways to help protect, preserve, and maintain our cultural resources and
landscapes from environmental hazards and neighboring developments. One method that is blazing the
trail for those in involved with preservation challenges are looking into the benefits of High Definition
Survey (HDS) also known as 3D Laser Scanning used to create accurate computer images of existing
structures and landscapes. The laser scanner uses a built-in digital camera to capture photos of structures
and their natural environment in micro speed time. The Laser beam travels from each selected target and
captures images called "Cloud of Points" that map the completed scanned area. The laser scans can then
be combined to show all sides or sections of a completed structure and surface. The collected information
from the scanned areas can be utilized to create a more accurate drawing or model and can be used to
monitor environmental effects that may cause damage to historic structures, and aid in future preservation methods.

Smetana, Debra (University of Notre Dame)  
[266]  Prestige in Death: Mortuary Evidence for Social Structure in Hopewell and Mississippian Societies  
The mound-building phenomenon of the Eastern Woodlands and Southeastern United States dates back thousands of years and is shared by a wide variety of prehistoric Amerindian cultures. Two of the most well known mound-building cultures, the Hopewell and Mississippian, inhabited roughly the same area, with the Hopewell phenomenon dating to the beginning of the Common Era and the Mississippian culture occurring about a thousand years later. Although these two cultures shared a common landscape and affinity for mound building and burial, most modern archaeologists interpret the two cultures as having very different social structures. In this poster, I will examine the presence and associations of prestige goods left in mound burials from the Hopewell and Mississippian cultures. The goal of this poster is to determine whether anything can be learned in terms of Hopewell or Mississippian social structure from these grave goods.

[256]  Fragmented Production, Fractured Power: An Examination of the Colonial Mining Landscape in Huancavelica  
An over reliance on official documents can constrain our understanding of power in the colonial encounter, creating the myth that colonial states acted as unified polities with singular purposes. In the Colonial Andes, the Toledan Reforms may superficially exemplify a triumph in early modern statecraft; moving thousands of people into planned settlements and dramatically reorganizing labor relations through the dreaded mita to support Hispanic mining efforts in Potosi and Huancavelica. However, archaeological approaches provide a different perspective, emphasizing how colonial decrees do not arrive as unaltered packages, but rather are negotiated amidst competing Hispanic and indigenous institutions long before they are emplaced locally. This paper will use settlement pattern data and local archival research to examine the changing power relations associated with the colonial mercury mining in Huancavelica. Preliminary results indicate that in practice, the state-mandated Toledan Reforms did not necessarily correspond with concentrated production or state control, but instead demonstrate how state, merchant, and indigenous interests intersected to produce a fractured landscape of power.

Urbanization and Village Nucleation: Causes and Consequences of Moving into Town

I survey theoretical and comparative work on urbanization and nucleation at two analytical levels: (1) Household decisions to move into villages and cities; (2) Larger social forces that stimulate nucleation and urbanization within agrarian regional economies. Primary drivers of village nucleation include defense, political administration, economies of scale, and institutional forces. At the urban scale, I explore these and other costs and benefits. Research on ancient Mesoamerican migration and urbanization can benefit from a better understanding of processes such as chain migration, migrant adaptation to urban conditions, and the ties urban migrants maintain with their village or region of origin.

A Western Subset of the North American Oikoumene: Regional Interaction between California and the Southwest

Drastic changes occurred in both coastal California and the Southwest during the beginning of the second millennium, including the intensification of internal trade and increasing complexity in sociopolitical development. Drawing from Peregrine and Lekson’s (2006, 2011) continental perspective and the inclusion of both small and large-scale dynamics, we suggest that developments in each area are influenced by both local and regional processes. In this fashion, we see California and the Southwest as components in a continental-wide interaction system spanning North and Central America. Within this system, we argue that interaction was sustained and regular, creating parallels in economic and political developments between the two areas. We offer archaeological and ethnographic evidence for the trade of prestige goods in the form of ceramics and textiles that we suggest moved westward from the Southwest in exchange for shell beads, asphaltum, and obsidian from coastal California. By expanding the scale of regional economic interaction, we hope to demonstrate the degree of connectivity between California and the Southwest, and establish parallels in social development and change between the Southwest and the far west.

Swift Creek Design Elements and their Layouts

Elsewhere we have argued that Swift Creek core design elements and their layouts—the shared ways in which the elements were arranged on the paddle—were culturally transmitted and, thus, serve as important characteristics that reveal the histories of sets of designs. With this principle in mind, we have worked with core elements whose layouts occur in three-guide-point setups and simpler one-guide-point setups. In this poster, we visually summarize the Swift Creek design corpus in terms of layouts and elements, both core and secondary, and assess the variation we observe across these sets in fill and finish.

Cross-Cultural Interaction in the ancient Egyptian and Nubian Borderland

Ancient Egypt and Nubia have a long history of interaction that led to both cultural and biological entanglements. Cultural and political boundaries shifted over time, with Egypt absorbing parts of its southern neighbor into an eventually far reaching empire, but also with independent Nubian kingdoms dominating Egypt at different periods, at one point with its kings ruling as Pharaohs. This paper examines the influences that flowed back and forth between Egyptian colonizers and indigenous Nubians, mapping the flows and intensity of cultural and biological exchanges diachronically through the graphic model developed by Green and Costion. This model can allow us to take into account the complex nature of interactions between Egyptians and Nubians and the multifaceted role that individual agency played in creating complex outcomes that simultaneously reflect multiple groups with varied interests.

The Great Basin Paleoindian Research Unit and the Ongoing Search for the First Americans

The Sundance Archaeological Research Fund (SARF) at the University of Nevada, Reno (UNR) was created in 1994 through a generous endowment from Joe and Ruth Cramer to conduct Paleoindian research in
the Great Basin. In 2010, in part due to Joe's wishes, the SARF evolved into the Great Basin Paleoindian Research Unit (GBPRU). While there are some new faces associated with the GBPRU, its central mission remains the same: (1) search for the earliest sites in the Great Basin; (2) develop a better understanding of Paleoindian lifeways in the region; and (3) place our findings into the broader context of the peopling of the Americas. In this paper, I describe my transition from graduate student to executive director working with SARF/GBPRU and highlight our recent work in Oregon's Warner Valley, where we continue the tradition of Paleoindian research established at UNR 20 years ago with help from the Cramers.

[325] Den of Thieves or the Temple of Doom? The Creation of Mythic Landscapes at Surtshellir Cave, Iceland

Surtshellir—one of the best known and largest lava caves in the North Atlantic—has historic and folkloric references spanning more than a millennium. Throughout, the cave is associated with horror—the end of the world, social dissolution, the inversion of religious and ethical certainties, mutilation, death, and betrayals—and with accounts of Viking Age chieftains and post-medieval peasant leaders reversing these terrors to restore the balance of life, locally or globally. Two tropes dominate these tales— that the cave was a base for outlaws in the 10th, 12th, or 16th centuries, or that it was the home of Surtur, a being who existed before the world was created and would destroy it, killing the Norse gods at Ragnarök. Preliminary investigations in Surt’s Cave identified standing Viking Age structures, massive deposits of faunal remains, and intact cultural deposits. Excavations of those deposits in 2013 provide new data on Surtshellir that encourage a re-conceptualization of the cave, redefine its role within Iceland and the Viking Age, and speak to both the inscription of mythic concepts onto newly settled landscapes by island colonizers and the integration of ritual and political power in North Atlantic chiefdoms.

[131] An Investigation of the Origin of Alaskan Fluted Points and Their Role in the Early Settlement of Beringia and the Americas

After more than 60 years of inquiry, fluted technology in Eastern Beringia is now confidently dated to the terminal Pleistocene at two sites in northwest Alaska and post-dates the Clovis complex by at least 700-1000 years. Competing hypotheses regarding the role of Alaskan fluted points in the early settlement of Beringia and the Americas persist—that Alaskan fluted points represent either a backwash of Paleoindian technology transmitted northward from mid-continent North America or an example of independent invention in the far north. This paper presents the results of a comparative technological and morphological analysis that investigates the relationship between Alaskan fluted points and other North American fluted-point collections. Discussion addresses the origin of fluted points in Alaska and how fluting technology may have been transmitted culturally across the region.

[147] Late Classic Provincial Politics: Chemical and Mineral Analyses of Late Classic Polychrome Pottery Paints and Pastes

Previous epigraphic and polychrome pottery investigations have identified the site of Motul de San José as the capital or one of several capitals of the Late Classic period Ik’ polity in Petén, Guatemala. Less is known about the regional relationships between Motul de San José and other important political centers in and around Lake Petén Itzá, such as Tayasal, Flores (Nojpetén), and Zacpetén. These centers may have been part of, allied with, or politically autonomous of the Ik’ polity. This paper examines regional political-economic relationships between these Lake Petén Itzá centers as well as between the lake centers and the more politically dominant capital of Tikal through the chemical (LA-ICP-MS, INAA) and mineral analysis (ATR-FT-IR, XRD, and EXAFS) of Late Classic Maya polychrome paints and pastes.

[194] Introduction: Abundance as an Economic Principle

Archaeologists generally have focused on scarcity as the most significant economic principle governing human-material dynamics. Abundance can be characterized as an equally compelling aspect of the economic realm starting with our earliest human ancestors, who were likely to have used resource quantity as a determining criterion of settlement location and landscape investment. A cognitive predisposition to seek out bountiful locales subsequently was augmented by the capacity to produce abundance through agricultural activities and object manufacture. Masses of tangible items could be utilized by elites and non-elites alike for a variety of ritual and social purposes, including the performance of plenitude at sacrifices and feasts. The desire for and encoding of abundance can be discerned from a variety of archaeologically-visible mechanisms, from the construction of massive storage facilities to the incremental creation of middens and waste dumps. An ancient appreciation for mass quantities also can be discerned through the use of style changes to increase the visible repertoire of goods such as pottery, textiles, and metal objects that encoded dynamic social relationships of identity and group cohesion.

[198] Political Landscapes of the Upper Desaguadero River Valley, Bolivia

This paper discusses the ways in which politically marginal groups living along the Desaguadero River in the Altiplano region of the Bolivian Andes negotiated the expansion of states. Drawing on both archaeological and historical data I compare two moments in the long term historical ecology of the Upper Desaguadero River: the consolidation and expansion of the Tiwanaku state between AD 500 and 1100 and the incursion of the Spanish colonial state into the region beginning in the late 1530s. At both times, the fishers of the Desaguadero River constituted a minority in a region dominated by agropastoralists. During the Tiwanaku period, the data suggest that these communities became key nodes in the circulation of people, animals, objects, and ideas. During the Spanish colonial period, these communities resisted incorporation into the colonial state and the river became a staging ground for politically motivated raiding and rebellion. For much of the 17th century the Upper Desaguadero River was effectively an internal frontier within Spanish colonial territory. A consideration of this riverine landscape at these two moments highlights the diversity of ways in which politically marginal groups, like the fishers of the Upper Desaguadero, actively negotiated the vagaries of expansionary political formations.

[208] An Experimental Approach to Fishing Net Replication

The archaeological record provides evidence of the widespread exploitation of fish in prehistoric Eastern North America, but the amount and quality of evidence for fishing technology is limited. Although nonperishable items such as netsinkers may be common and fishhooks made of bone and other material also are known, there are few intact examples of nets that were widely used in the process of fishing. All of the remaining examples of prehistoric netting in Eastern North America were constructed of cordage, although there are representations of differing construction methods that resulted in a multitude of final products through materials, types, overall sizes, and mesh sizes. Thus, an understanding of cordage construction in general, as well as its association with net making, is essential. One potential way of understanding the range of netting technologies utilized in the Middle Atlantic region is to examine
impressions left on identified net impressed pottery and replicate these technologies. The Delaware River provides an excellent opportunity because of its history of fish-based subsistence and the presence of net marked ceramic wares, for researchers to solidify their understanding of prehistoric netting technology.

[233] Foodways in Colonial Western Pennsylvania: An Analysis of Faunal Remains from Hanna’s Town
Hanna’s Town, a historic settlement in Westmoreland County, Pennsylvania, is known for its status as the first county seat and court of justice west of the Alleghenies. This poster presents data regarding access to and treatment of food items on the frontier with a specific focus on the faunal remains from the pit features associated with the three areas known as Foreman’s Tavern, Hanna’s Tavern, and Irish House. With the cooperation of the Westmoreland County Historical Society and Indiana University of Pennsylvania, faunal remains from these three areas of the site were carefully analyzed in order to answer general questions regarding the subsistence practices and sociocultural diversity of 18th century western Pennsylvania frontier communities and their residents. Topics such as taxonomic abundance, skeletal frequencies, butchering practices, and indicators of ethnicity and socioeconomic status were addressed using standard zooarchaeological methods. For each area, proportions of domestic game versus that of wild game were discussed, as well as the ways in which the cuts of meat present and the butchering practices employed vary. This analysis addresses specific elements of Western Pennsylvania colonial frontier life that have not previously been discussed relative to the Hanna’s Town community.

[235] Spatial Autocorrelation and the Changing Organization of Social Inequality in Colonial Philippines
Spanish colonization in the Philippines brought drastic social reorganization. It arrived unevenly across the archipelago and via differing vectors, including state representatives backed by military force and missionaries who dispersed as individuals to proselytize. While new products were incorporated by the transitioning elite as indicators of status, some “prestige goods” from the pre-contact period of the 13th-16th centuries continued into the capitalist political economy beginning in the late 19th century. I summarize these material indicators of high status, namely imported Chinese and Southeast Asian ceramics, found over a four year survey and excavation project in the Malangwa watershed on Negros Oriental, Philippines. The results of a spatial autocorrelation analysis reveal significant and changing patterns in the distribution of these artifacts across time. Theories that posit identity and inequality as social process, instead of as fixed positions, help guide the interpretation of these results beyond discussion of political economy and social organization to investigating the changing cultural meanings of enduring prestige items. I also address how spatial data at community and regional scales can be interrogated to discern social patterns using global and local indicators of spatial autocorrelation.

[251] “When Frog Stole the Waters”: Mississippian Megadroughts, Migrations, and Revitalization Movements
During the colonial period, many indigenous Native American societies responded to unpredictable external stresses through large-scale migration and revitalization movements. Recent climatic models suggest that between A.D. 1250 and 1550, the interior South experienced different but equally unpredictable external stresses in the form of highly variable weather conditions, including megadroughts. Here I evaluate evidence for the time-transgressive spread of several late prehistoric “archaeological horizons” to test the hypothesis that large-scale migration and revitalization cults may be equally characteristic of the Mississippian era, albeit due to different stressors. I conclude with an evaluation of relevant indigenous folklore concerning drought and floods.

Smith, Marvin and David Hally (University of Georgia)
European artifacts, such as beads, bells, and iron cutting implements are frequently found in sixteenth-century Native American archaeological sites. How were these items obtained by Native Americans? Many mechanisms of acquisition can be identified from historical documents and the types of artifacts, but often it is the archaeological context of the artifacts that informs us the most. Mechanisms to be
investigated include European gift giving, barter (both European and Native), tribute, redistribution, theft or pilfering, combat, and shipwreck salvage.

Smith, Lisa (University of Montana)  
[290] Late Period Household Socioeconomics in the Middle Fraser Region of British Columbia and Its Implications for Understanding the Early Colonial Period  
Housepit (HP) 1 of the St’at’imc site of the Middle Fraser region in British Columbia is among a few well-sampled late precontact houses in the area, and when compared to data from later houses, it is an ideal baseline from which to measure the effects of the Fur Trade on household socioeconomics. Evidence demonstrates occupants of this multifamily dwelling were relatively egalitarian with a subsistence strategy focused on anadromous salmon. During the early colonial period, there was a notable decline in salmon reliance, as evidenced by faunal data of Housepit 54 of the Bridge River site, suggesting this keystone resource was impacted by the Fur Trade -- a finding that is also reflected in local ethnohistories and native oral traditions. Couched in Practice theory and household archaeology, this research investigates daily activities of individuals within the St’at’imc community. It provides not only greater understanding of late period households in the Mid-Fraser, it informs discussions on incorporation of traditional knowledge to generate a more nuanced narrative of the past.

Smith, Morgan (Texas A&M University)  
[315] Archaeology at Wakulla Spring: Historical Investigations and Future Directions  
Wakulla Spring, located south of Tallahassee, Florida, has long been thought to possess the potential to be a promising source of Paleoindian and potentially Pre-Clovis archaeological information. This is evidenced by cultural material that has been found in and around the spring and by the fact that the region surrounding Wakulla Spring has yielded an anomalous concentration of Paleoindian age cultural material. Past research at Wakulla Spring has been limited to biology, water chemistry, and paleontology, with archaeology having served as ancillary information in texts. In the past, several mastodons have been removed from the spring in association with stone tools. No provenience information exists from the recoveries however, and the small archaeological assemblage from Wakulla Spring consists of entirely of ex situ osseous and stone tools in private collections. Several recent developments, most notably the analysis of private archaeological collections from the spring, successful terrestrial excavations around the spring conducted by Dr. James Dunbar, and the discovery of a mastodon potentially in situ in the spring run, have made it apparent that Wakulla Spring needs to be re-evaluated as a locale to study First Americans archaeology.

Smith, Craig (Cardno ENTRIX)  
[324] Hunter-Gatherer Resource Intensification: The Uinta Phase in Southwest Wyoming  
Resource intensification has been an important concept for understanding changes in hunter-gatherer subsistence. The excavation of over 50 sites in southwest Wyoming dating to the Uinta phase, 1800-1000 years BP, provides an opportunity to explore this concept among hunter-gatherers in an environmentally marginal area. This phase when compared to proceeding phases is marked by a greater reliance on seeds from weedy species, a focus on a wide variety of large and small animals, and an increase in the number of sites. It appears to be a time of increased population, the probable constriction of territory and range, and decreased mobility.

[332] Survey on Hospital Island: Results from the 2013 Field Season on Isla del Rey, Menorca  
Isla del Rey is a small off shore islet located in the harbor of Mahón on the Balearic Island of Menorca (Spain). Nicknamed “Bloody Island” in the 18th century, the island is well known for its British naval hospital, constructed over multiple periods of British occupation. Along with strong ties to British, French, and Spanish history from the 18th to the 20th centuries, the islet is also host to a Paleochristian basilica, roughly dating to the 6th century C.E. In 2013, the Boston University Field School in Archaeology and Heritage Management began investigating the northern third of the island, which had not been previously explored. The goal of the survey was to provide a systematic analysis of this area, completing the archaeological picture of the islet, while educating field school students. Although a degree of both abundant surface remains and diachronic sample representation was expected, the final results were remarkable, potentially closing temporal gaps and expanding our knowledge of human use of Isla del Rey.
from the prehistoric to the modern era. This paper will present for the first time the results of the survey as well as related test pitting carried out in 2013.

Smith, Michele (Research Associate Haffenreffer Museum of Anthropology)

[336]  Mineralized Textiles from Viking Burials from Iceland, A.D. 874-1000
The textile corpus from Iceland’s Viking Age is far less abundant than larger collections dating from the 14th-19th century. Without mineralized textile pseudomorphs stuck to iron or bronze grave goods from Viking period burials, the Icelandic corpus would be incomplete. This mineralization provides data otherwise lacking and has helped us to establish a clearer understanding of textile traditions during Iceland’s settlement period. These pseudomorphs suggest that Viking Age textiles were woven differently than in subsequent centuries and that their closest parallels were with Norway. By the 11th century, weaving traditions had changed quite drastically suggesting that foreign influences had made their way into Icelandic weaving, possibly as the result of female slaves from the British Isles bringing with them different weaving traditions. These new traditions established the framework for the emergence of vaðmál—a cloth-currency that became the main exchange good used in Iceland throughout the Middle Ages. Without the process of decay and mineralization these important early textiles would have been lost, along with vital information they provide.

Smith, David (Anthropology, University of Toronto, Mississauga)

[342]  Singing Pots: Symmetry as Cultural Expression in Huron-Wendat Ceramics from South-Central Ontario
This paper demonstrates that symmetrical patterning is the dominant theme of both form and decoration of Huron-Wendat pottery. It is argued that Huron-Wendat potters fully understood the principles of plane pattern and three-dimensional symmetry and were able to manipulate symmetries and experiment within the parameters of a community of practice. Specific examples from the pottery assemblage of more than 5,000 pots from the Keffer site, a completely excavated late 15th century AD Huron-Wendat village situated in the Don River Valley, will be presented.

[195]  Xcoch: An Enigmatic Large Maya Center in the Puuc Region of Northern Yucatan
Xcoch was a large Preclassic center exceeded only by its Late Classic period occupation. Though water management and agricultural intensification were always critical in this drought prone hilly region, the presence of a deep water cave near the site center, a massive central acropolis, and widespread pyramid architecture make Xcoch rather unique in the settlement history of the region. This paper will discuss the cave, water and settlement features, and their relationships to cycles of drought recently reconstructed via speleothem analysis near Xcoch. The findings begin to reveal a complex picture of long, dynamic cultural development, human ecodynamics, and rapid declines in a region once thought to be relatively late and short-lived in the history of the Northern Maya Lowlands.

Snead, James (California State University Northridge)

[159]  Canonical Sites and the Legacy of Place in American Archaeology
Histories of American archaeology remain largely divorced from the places in which archaeological work has taken place. Our general preference for exploring trajectories of professionalism has left out many significant stories: the general lack of interest in landscape is particularly ironic since engagement with material contexts is fundamental to the archaeological process. At various times in our history, specific places have played critical roles in structuring archaeological interpretation. These “canonical sites” (following Rosemary Joyce’s “canonical artifacts”) were visited, studied, and attracted considerable comment. Their centrality to the narrative, however, is often completely idiosyncratic, reflecting proximity to travel routes, aesthetic appeal, or other values that are relevant only to the Euro-American viewer. This paper looks at two canonical sites of central importance to the development of American archaeology in the first half of the 19th century: the Grave Creek Mound (WV), and the Selzertown/Emerald Mound (MS). Both sites are preserved today, but in contrast to their 19th century notoriety, contribute little to the modern archaeological syntheses of their surroundings. Viewed in context, however, they provide examples for the relationship between history, place, and the canon construction in archaeological
Landscape modification due to anthropogenic burning practices has a deep history in human-environmental relationships. Although anthropogenic burning is commonly recorded in both prehistoric and ethnographic contexts, few archaeological projects engage in landscape-scale investigations of the social and environmental processes behind these practices. This project explores the complexity of anthropogenic burning by focusing on quantifiable components of a human-altered fire regime within a modeled landscape. Through exploratory agent based modeling (ABM) and geographic information systems (GIS), the human fire regime is examined through dimensions of fire intensity, extent, type, and frequency. Systematically modeling anthropogenic fire under differing conditions will allow archaeologists to explore both cultural and environmental aspects related to the dynamics of human-fire relationships in both past and present contexts.

Snow, Susan (San Antonio Missions National Historical Park) and Paul Ringenbach (Bexar County Historical Commission) [119] The Modern Cultural Landscape of the San Antonio Missions: How does it reflect the People of the Missions?

The five 18th century mission complexes of San Antonio, including over 50 structures, archaeological ruins, and landscape features, represent the most complete extant example of the Spanish empire’s efforts to expand and control using the missionary system. This paper will examine these extant remains and discuss how these features represent the indigenous peoples who built the system and the interwoven mission culture that evolved during the mission period and remains the core of the unique culture of San Antonio and south Texas today. Evidence of the influence of indigenous peoples may be represented in some of the extant architectural features. Individuals and families who identify themselves as mission descendants varyingly identify themselves as indigenous, Spanish, or both, but they all have memories of various aspects of the cultural landscape that they associate with their mission identity. As the missions are considered for World Heritage status, it is this testimony to a thriving cultural tradition that continues to keep the missions as the living center of San Antonio, the 7th largest city in the United States.

Snow, Meradeth [247] see Durand Gore, Kathy

Sobel, Elizabeth (Missouri State University) [290] Explaining Prestige Goods: Applying Helms’ Cosmological Framework in the Archaeology of the Pacific Northwest

Archaeologists studying sociopolitical complexity in the Pacific Northwest have extensively studied how two classes of objects - exotics and highly crafted items – operated as prestige goods in indigenous societies. Extant research focuses on the ways that people acquired and distributed these goods, but has not rigorously addressed the question of why people imbued these objects with prestige. Generally, when addressing this question, we uncritically use ethnographic data to identify prestige goods, and we invoke formal economics, citing the rarity and labor costs of these goods, to explain their prestige values. Mary Helms offers a higher level explanation, arguing that the prestige values attached to exotic and highly crafted goods are rooted in cosmology. Helms proposes that all non-industrial cultures ascribe extraordinary power to long-distance trade and skilled crafting, based on cosmologies that position long-distance trade and artisanship as transformative acts linking the known realm “inside” society with the unknown, supernatural, powerful realm “outside.” I use Helms’ model, and a critical evaluation of ethnohistorical data, to interpret the archaeological record of the Lower Columbia River. I then assess the
effectiveness of this approach for archaeological analyses of relationships among trade, specialized production, and sociopolitics in the broader Pacific Northwest.

Sobur, Marta (Harvard University)

Sustainability in Early Dilmun Mortuary Economy

Collapse is a well-represented theme in the study of ancient civilizations. Well-understood examples include the deforestation of Easter Island, or the dissolution of political cohesion among the Maya, while others, such as the demise of the Indus River Valley civilization, are still debated, with the likelihood that inadequate responses to environmental degradation played a key role. The archaeological narratives of collapse paint a picture of human nature as self-destructive, and overshadow the numerous efforts to achieve sustainability and manage resources, which are often expressed as small-scale activities.

Perhaps the last place to look for evidence of sustainability efforts is in the realm of mortuary rites; yet surprisingly, unique examples of recycling of scarce resources come from the burial mounds of Early Dilmun period civilization (2300-1700 B.C.) of Bahrain. The collection of over 50 soft-stone (steatite/chlorite) vessels from the cemetery at Hamad Town, curated by the Bahrain National Museum, contains evidence of recycling and repair activities. The vessels are a common funerary offering in the burial mounds and the care given to their maintenance suggests that they were heirlooms. In this paper, I will contextualize soft-stone recycling in the holistic picture of mortuary economy of the Early Dilmun civilization.

Ballcourts, Sweatbaths, and Caves: Sacred Landscape at Chawak But’o’ob

Cave 1 at Chawak But’o’ob, located in the heart of the site’s public architecture, is surrounded by a ballcourt, a sweat bath and a sinkhole. Survey and excavation conducted during the summer of 2013 by a California State University, Los Angeles project revealed a utilization of the cave that differed from other areas of the Maya lowlands. Nevertheless, analysis of the architectonic and natural elements in the Ballcourt Complex make it clear that this was intended as the focus of community identity. Caves are associated with people’s first emergence onto the earth’s surface and this forms a basis of the group’s claim to the land. Ballcourts, according to ethnohistoric sources, were the first structures built in a new community and formed the focus of community identity. Ballcourts and caves are both seen as having connections to the water and the underworld. Sweat baths are also seen as a form of cave. There is a great deal of freedom in the placement of architectonic elements but natural elements such as the cave cannot be moved. Thus, the location of the natural elements probably determined the elaboration of this space.

Solar-Valverde, Laura (INAH Zacatecas)

Coast-to-Coast: Evidence for Aztatlán’s Macro-Regional Interaction

Around 900 B.C. the Aztatlán Network, until then circumscribed to the Pacific Coastal Lowlands, enters a period of apogee. This is discernible by the incorporation of northwest inland sites to its economical and ideological system. At the same time, the Mexican Gulf region experiences a “regional development” not clearly lead by a single polity, but still articulated by what Lee Parsons (1969, 1978) called the “Peripheral Coastal Lowlands”. Ceramic and architectural complexes in both regions differ typologically. Nevertheless, we consider that simultaneous strengthening and expansion of this East and West centered network, which at one point seem to converge in the Mixtec region, is reflecting a systemic relation. To sustain that proposal, this paper outlines distinctive iconography and cultural patterns, as well as the sharing of similar artifacts and the synchronic emergence of early metallurgy in both areas. A relation between Eastern and Western polychromes was mentioned decades ago by one of Aztatlán’s main researchers, Isabel Kelly (1941). From a World Systems perspective (following Chase-Dunn and
Hall 1997), it is now suggested that these regions were once articulated by a main Prestige goods and/or Information Network, involving much the same conception of ritual’s active expressions.

[241] Species Identification in Keratinous Tissues using Mass Spectrometry: Potentials and Limitations

Keratin-made artifacts, textiles, but also objects made out of horn, baleen and tortoiseshell tissues, are rarely found in archaeological contexts unless specific conditions are met that prevent extensive biodegradation from micro-organisms. Even when these artefacts survive, processing of the raw material, use and diagenetic changes combine to make identification difficult through visual examination, therefore a minimally destructive methodology for species identification is required. Using the PMF method (Peptide Mass Fingerprinting with MALDI-TOF-MS) complemented with nanoLC-ESI-MS/MS, diagnostic peptide markers (at the genus/species levels) are presented here for a range of wool-producing species, and for tissues such as baleen, horn, quill and tortoiseshell.

Peptide mass fingerprinting is an efficient method to characterize keratinous tissues even when the recognizable structural information has not survived (the scales on hair or the striations on horn). It requires little material but the state of degradation (protein hydrolysis) is a limiting factor. By examining a range of keratinous tissues of different ages (4000 B.C. to medieval times) and preserved in variable conditions (peat-like soil, frozen soil, through mineralization or desiccation), we also explore here the limitations of the technique in regards to the degradation of fibers.

[21] Roads and Social Space: Exploring Intrasite Accessibility Using Lidar Data from Angamuco, Michoacán

The distribution of space within the built environment of the heavily urbanized site of Angamuco, Michoacan, provides the framework to explore different scales of social interaction and social organization. The placement of roads, paths and trails contributes to the delineation of physical boundaries that define social division of space at four different scales of interaction: household, complejo, neighborhood and district. Furthermore, the physical and material characteristics of this trail system contributed to a differential accessibility, which should have resulted in social interactions and negotiations when moving around the site. In this sense, we propose that trails, roads and paths are agents that help define the social configuration of this ancient city. Here we examine a vast LiDAR database of over 8km2, which allows us to examine the urban configuration of Angamuco using network-base spatial analysis from GIS to explore the differences in accessibility within the site.

Solis, Reyna (POSGRADO IIA-UNAM)

Five hundred lapidary greenstone elements have been recovered in the surrounding structures of the Great Temple at Tenochtitlan, many of them were buried inside diverse buildings and correspond to different temporalities attributed to the last Tenochcan rulers of the Triple Alliance. The purpose of this paper is to show the technological analysis and the organization of production involved in the manufacture of these pieces, using experimental archaeology, optic microscopy, and Scanning Electron Microscopy. This analysis was applied in order to determine patterns among the procedures, techniques and tools. Finally, I will compare the results obtained with those reported for the greenstone objects from the Huey Teocalli, in order to reconstruct the sequence of production of them and to know if both assemblages shared the tools and manufacturing techniques, perhaps because some of them were produced in the same workshops.

[63] An Isotopic Investigation of Lagomorph Management and Breeding at Teotihuacan, Mexico

The means by which societies produce and distribute food has important implications for their social and economic organization. To this end we investigate the acquisition of lagomorphs (rabbit and hares) at the ancient metropolis of Teotihuacan. Faunal studies suggest that lagomorphs were one of the most commonly represented vertebrates at the ancient city, and archaeological evidence suggests that certain apartment compounds may have managed or bred these small mammals as a renewable source of...
protein or for trade. Through stable isotope analyses (δ13C, δ18O, δ15N) of lagomorph bones from four locations across the ancient city, Oztoyahualco, Teopancazco, the Caves associated with the Sun Pyramid, and the fill of the Moon Pyramid, we explore dietary variation of these small mammals. Our results indicate that lagomorphs from Oztoyahualco, the residential compound with the most evidence for lagomorph breeding, display the highest δ13C values, suggesting that these animals consumed significantly more maize products than lagomorph of other contexts. These data support the hypothesis that rabbits and hares were in fact bred for consumption at Teotihuacan. Moreover, since production appears to have been conducted at the level of residential compounds, this study increases our understanding of the economic organization of New World cities.

[289] Population and Organization of a Basketmaker III Settlement in Southwest Colorado

The Basketmaker Communities Project is evaluating the surface and sub-surface signatures of a Basketmaker III settlement in the Village Ecodynamics Project study area of southwest Colorado. Seventy-one habitations were re-surveyed to refine the occupation sequence within the settlement while electrical resistivity imaging was applied to clarify the settlement's density. This study has provided insight into the organization of communities during the Basketmaker III period and provided a new method for estimating early Pueblo momentary populations in the Mesa Verde Region.

Sosa Aguilar, Danny

[174] Late Holocene Obsidian Exchange in the Baja California Peninsula

Very few studies focus their attention on obsidian artifacts from the Late Holocene in the Baja California Peninsula. The published data from San Quintín, El Rosario, Guerrero Negro, Isla Cedros, Bahía de Concepción, San Borja, Bahia de los Angeles, and San Ignacio provide valuable information pertaining to sourcing, and they are relevant to addressing possible exchange routes. In a peninsular context, obsidian appears restricted to small quantities and specific locations. Obsidian assemblages can be situated within a social and meaningful landscape. Throughout the peninsula, obsidian procurement, mobility, and interaction during the Late Holocene were affected primarily by two factors: (1) the physical constraints of the Baja California environment; and (2) the free will to situate and to imagine a cultural landscape based on agency, social relationships, and beliefs. The rich ethnohistoric record, ethnographic record, cultural histories, burials, and rock art of Baja California provide sufficient contextual information to develop a geographical picture of obsidian exchange during the Late Holocene. The development of alternative interpretations encourages the multifaceted social and cultural dimensions of small-scale societies often ignored within the hunter-gatherer literature.

[147] Middle Preclassic Pottery Use and Production at Four Sites in the Petén Lakes Area

Recent work in the Petén Lakes area of Guatemala reveals widespread occupation during the Middle Preclassic period (1000-350 BC) in areas extending from the western shore of Lake Petén Itza to Lake Salpetén. A new study of pottery from the sites of Nixtun-Ch’ich’, Tayasal, Ixíuí, and Zacpetén, reveals similarities and differences on macroscopic and compositional levels suggesting that while early pottery production in the Petén lakes area shared some characteristics, local variation in both form and paste composition is evident. This indicates that discernible community-level differences were maintained at the level of production. Contextual analysis provides indications of population differences among the sites during the Middle Preclassic period, with Nixtun-Ch’ich’ providing the largest sample of early contexts in the area. These contexts also suggest that pottery played an important role in the construction and dedication of architectural spaces during the early phases of community development. This paper explores the production characteristics and the use contexts of early pottery in the Petén Lakes area, highlighting the developing complexity of settlement and craft production during the Middle Preclassic period.

[79] Window into the Past: Two 19th-Century Unmarked Burials in Roy New Mexico

During the summer of 2013, two bodies were exhumed from burial contexts in Roy, New Mexico. The bodies, found in unmarked graves, were disturbed when a backhoe operator dug a pit to install a new
septic system. Preliminary laboratory evaluation indicated that the remains were those of two European males; one adult and one subadult. Grave goods, including coffin wood, glass, hardware, clothing, and shoes, together with a pocket watch and wooden pencil were recovered. Early analysis of the grave goods suggested that the burials date from between 1890 and 1904. Following standard bioarchaeological methods, an assessment of the remains helped determine sex, stature, and ancestry, along with evidence of pathologies and skeletal trauma. These burials became the central elements of a broader research effort – through the methods of micro-history – to understand the life, times, and general health of the early settlers of this important historic settlement on the western edge of the Great Plains.

**Positioning Swedish Rural Settlement in Preliminary Landscape Analyses: Medieval Farmstead and Historical Croft Settlement Patterns**

The southern Swedish rural landscape has been increasingly studied in the last thirty years, but relative settlement in those areas of medieval farmsteads and 17-19th century crofts should be increasingly considered. While crofts (Swedish 'torp') have been more popular in recent years in the fields of history and historical geography, the archaeological research on them is less abundant. The settlement pattern for medieval farmsteads in forested, rural areas is less well-known from all three perspectives. Pollen and archaeological records have indicated that some crofters settled in previously-inhabited areas of the Swedish uplands. Future avenues for the medieval research are shown in starting with known crofts and medieval farmsteads to compare their inhabitants’ land use choices with regards to agricultural and mixed traditional economies. If the later Swedish historical settlement choice were predicated in some degrees on the subsequent character of the post-medieval landscape, archaeologists might approach rural settlement on a more long-term scale and look for evidence of medieval farmsteads near croft remains. The potential of the ArcGIS software package for historical site survey is outlined in various methods, citing as well other successes in its use in relation to historical archaeology and for rural landscape research.

**LA-ICP-MS Sourcing of 33 Clovis Projectile Points from the Gault Site (41BL323), Salado, Texas**

A key tenet of Clovis period hunter-gatherer mobility is the utilization of large ranges based on the appearance of exotic raw materials, particularly chert, in Clovis assemblages. The identification of the sources of chert in Clovis assemblages is problematic as it has relied on macroscopic properties. Macroscopic characteristics of chert can be highly variable in a single outcrop, occur across very large areas, and have correlates in unrelated and far removed contexts. A chemical analysis approach was utilized that potentially offers advances in the capacity to link chert artifacts to their sources. Trace element data was recovered from 33 Clovis projectile points from the Gault Site using Laser Ablation – Inductively Coupled Plasma – Mass Spectrometry (LA-ICP-MS). This data was compared to trace element data from 224 primary geologic samples of chert from multiple primary sources across the Edwards Plateau in Texas and 18 secondary geologic samples of flint from the Knife River near the Sentinel Butte formation in North Dakota. The Clovis points were compared to the geologic sources using canonical discriminant analysis to establish group membership at three spatial scales: macro-regional (greater than 500 kilometers), regional (between 30 and 500 kilometers), and local (between 1 and 30 kilometers).

[70] Ancient Maya Eminent Domain: Terminal Classic Period Royal Appropriation of Actun Lak Cave, Cayo District, Belize

Jim Brady’s scholarship has revolutionized Maya cave archaeology with broad theoretical contributions as well as narrowly focused studies resulting in over 100 publications. Two overarching themes tie much of his work together. The first is that caves were highly charged ritual-political spaces. The Maya understood particular caves as the emergence places of their communities, while others to be the abodes of chthonic beings that required ritual attention. The second theme is that they were heavily modified through practices such as speleothem breakage, constructions, and caching. This presentation brings these two themes together to understand how and why Actun Lak cave came to be appropriated by a Terminal Classic period ruler of the pre-Hispanic Maya site of Pacbitun in central Belize. In particular, I discuss how changes in the artifact assemblage signify a movement away from open, public access to the cave in the Early Classic period, to its final use as a restricted royal place in the Terminal Classic. I argue that a series of architectural modifications made to the interior and exterior of the cave, in conjunction with a speleothem altar in the rear, were designed to help the king bring much-needed rain to the drought-ridden Pacbitun community.

[46] Lithic Procurement at Tsiping’uinge during the Late Coalition Period

The Late Coalition period (A.D. 1300–1350) village of Tsiping’uinge, known to the Tewa as “the village at the mountain of the chipped stone," was well situated on the flanks Cerro Pedernal to control the primary source of Pedernal chert. This important lithic material was widely used from Paleoindian times through the Historic period. I investigate whether the ancestral Tewa villagers at Tsiping’uinge controlled access, production, and distribution of Pedernal chert across the northern Rio Grande region by conducting an analysis of the site’s previously collected lithic assemblage. This includes examining raw material type and procurement and reduction technology. My analysis is then compared to lithic data from contemporary Ancestral Pueblo sites along the Rio Chama and Pajarito Plateau, as well as lithic material found at the Pedernal chert quarries, to understand the economic relationship between village and the material source. I then address the larger questions of regional patterns of interaction and ancestral Tewa landscape use.

Spence-Morrow, Giles (University of Toronto)

[59] Pillars of the Community: Household Social Reproduction, Domestic Mimesis and Cyclical Renovation of Late Moche Ceremonial Architecture at Huaca Colorada, Jequetepeque

Amongst the vast array of subjects depicted in the Moche ceramic corpus, the subset that clearly depict gable-roofed architectural spaces is widely accepted to refer to structures that have been uncovered archaeologically at the summits of numerous huacas across the North Coast of Peru. With mounting evidence that these structures served both ceremonial and residential functions for elite members of Moche society, the visual shorthand of a simple roof becomes a charged symbol of the archetypical household. Using recent excavations of precisely such a structure at Huaca Colorado as a case study, this paper will argue that through socially regenerative ritual performances involving communal efforts of reconstruction, the structures at the peaks of huacas stood as a marker of corporate affinity, a sign connecting the public with the elite. As a form of household social reproduction, such acts of construction and renovation would extend kin-based domestic models across generations, perpetually performing centralized ideology through the incorporative act of construction. By housing the ruling elite at the peak of huaca structures, the entire monument becomes a representation of an idealized central house, with personal communion with a leader or authority figure serving to legitimize and incorporate an individual into a community.

[20] Late Third Millennium B.C. Agriculture in the Foothills of Central Asia: A Mixing Zone for East and South Asian Crops

Pre-Silk Road interactions through Central Eurasia fostered the spread of agriculture throughout the eastern piedmont zone. A growing body of archaeobotanical evidence from across Eurasia is indicating that economy in the Bronze Age was complex, with people in some regions focusing pursuits more on mobile pastoralism and others on mixed agropastoralism. Areas with mixed agropastoral economies, such as the forest-steppe of Ukraine and the mountain foothills of Kazakhstan, had very different crop repertoires, and therefore, appear to have adopted agricultural technology and knowledge from different parts of the Old World. Eastern Central Asia was a melding zone for crops spreading out of China (broomcorn and foxtail millet) and South Asia (wheat and barley). In this intermediary zone a diversified economic system was developed by combining these distinct crops. As these crops spread through Central Asia, some people adapted them to fit mobile pastoral economies in other populations they replaced previously established agricultural regimes.

[278] Could Neanderthals Boil?

Neanderthal sites are largely devoid of fire-cracked rock, and boiling pits are similarly absent. These telltale signs of stone-boiling first appear in the Gravettian. Boiling technology, therefore, is generally thought to be an invention made by modern humans. Curiously, it is common knowledge among the public, but seemingly not within the archaeological community, that one can boil water in perishable containers without utilizing heated stones, placing hide, paunch, bark, or paper container directly over flames or on hot coals. Numerous wilderness survival manuals, and books of experiments that children can do in their own kitchen, describe how to boil water in a paper cup. One recent YouTube video even shows someone boiling water in a paper cup with a blowtorch! Traces of betulin-containing mastic, produced only by pyrolysis in an oxygen-free environment, has been found on several Middle Paleolithic stone tools, clearly demonstrating that Neanderthals utilized birch bark and, though speculative, increases the likelihood that they also used birch bark to make containers. The discovery of starch grains in the dental calculus of a Shanidar Neanderthal with a morphology suggestive of wet cooking makes it increasingly probable that boiling in perishable containers—without heated stones—was part of Neanderthal culinary technology.

[75] Vulnerabilities to Food Security: Contributions from the Prehistoric US Southwest Archaeologists are well positioned to contribute to the development of strong policies that establish and sustain food security. Long time spans in the prehistoric record allow us to identify the vulnerabilities that emerge and persist to undermine sustainable food security, as well as the actions that enhance it. In this paper, we identify eight vulnerabilities and illustrate how changes in vulnerability loads impact food security and the experience of food shortage. We then explore the specific role of one of those vulnerabilities: lack of adequate and scale-appropriate food storage. We show that the management of food storage at household and community scales is an enduring and a critical component of a food security portfolio. The cases explored come from the millennium of indigenous occupation in the US Southwest before European contact.

[145] A City Minute: Viewing Concepts of Temporality and Urbanism through the Lens of Poverty Point
Our conversations about urbanism are often interlaced with unstated assumptions about the temporal relationship between the place in question and the people inhabiting that space. Here, I explore how our understanding of urbanism shifts when faced with an archaeological site that meets many of the classical standards of an urban center, but was only occupied in this way for a short period of time. When the social structures and institutions often categorized as diagnostic indicators of urbanism are relatively ephemeral, how does that reflect upon our belief in their importance as indicators of the development of social complexity? The Poverty Point site, a Late Archaic mound center located in the Lower Mississippi River Valley, offers a foundation for questioning our assumptions about urbanism's place in the development of societal complexity, thereby throwing the analytical viability of these traditional archaeological markers into question.

[111] Medicine at the Mines: Worker Health and Medical Care at Hammondville, New York, 1873-1893

Hammondville was a small company-owned iron ore mining town located in the Adirondack region of Upstate New York. The Crown Point Iron Co. (C.P.I.C.), which owned and operated the village, provided most of the amenities of daily life including a company physician. This meant that the residents of Hammondville had access to a professionally trained doctor, an unusual situation for many working-class immigrant laborers in the late nineteenth century. Through an examination of documentary and archaeological sources, this paper examines how Hammondville residents viewed professional medical care and made use of the doctor's services. Local newspaper accounts and town death records provide information about the types of injuries and ailments that most commonly affected Hammondville residents and archaeological materials excavated from house yards in the village provides evidence of the types of domestic and professional medical care utilized.

[317] Experimental Archaeology: What Can We Learn in the Long Run?

Experimental archaeology can provide insights into the subsistence activities of prehistoric people. At the Range Creek Field Station, in east central Utah, students participate in timed trials of the collection and processing of “wild” dietary staples to obtain return rates. These experiments are expected to augment previous experiments but they also have an additional component. Collecting rounds of targeted patches are scattered along 20 miles and 3000’ elevation of Range Creek Canyon and are expected to provide insights on the movement of prehistoric foragers as well as the placement of their base camps and villages. Patch productivities are expected to vary depending on annual rains and temperature at each location. These constraints will be tracked using two fully equipped weather stations and numerous rain gauges to add an additional dimension to this study. The proposed time depth of this experiment is expected to yield data relevant to understanding prehistoric subsistence and will likely demonstrate significant year-to-year variance in the return rates of the available options.

[103] Histological Analysis of Skeletal Remains at St. George’s Caye, Belize

The St. George’s Caye Archaeological Project in Belize was initiated in 2009 to gain a clearer understanding of the lives and identities of the colonial population in British Honduras. Excavations of the
site have focused on the analysis of cultural and skeletal remains uncovered in a disturbed and mostly unmarked cemetery. In 2012, a total of 21 burials had been excavated. Demographic information was determined for each of the individuals using traditional morphological and metric analyses. However, the analysis was limited due to the fragmentary nature of the remains and taphonomic alteration to the site. This was particularly problematic when trying to estimate the age and ancestry from the skeletal elements. In an effort to clarify the data, skeletal samples of a subset of the individuals were removed for histological, isotopic, and genetic analyses. A comparison of the preliminary data and the results of histological age estimation as outlined in Thomson (1979) are presented here. It is our hope that this and future analysis of the site will allow for a more complete understanding of the colonial site.

[247] Mortuary Practices of Fifty-Four Individuals Recovered from a Large Virgin Branch Puebloan Habitation in Kanab, Utah

This paper examines the mortuary practices for 54 individuals recovered from 29 burial features during the Jackson Flat Reservoir Project data recovery investigations in Kanab, Utah. All of the burials were excavated from a large Virgin Branch Puebloan site—42Ka6165—that was occupied during the Basketmaker II to Pueblo I periods. The portions of the site excavated contained over 30 pithouses, dozens of massive slab-lined storage cists and bell-shaped pits, and hundreds of extramural features. Human remains were concentrated in the oldest of the site’s three habitation areas, and also in a discrete cemetery area located between the habitation loci. The presence of an “oversized” pit structure, the prevalence of worked and unworked turquoise ornaments, plus the association of turquoise ornaments primarily with infants has implications for the importance of this site within the Virgin Puebloan region and possibly within the greater Southwest.

[243] Situated Learning & Gendered Social Fields: Crafting in Contexts of Shifting Global Exchange

A genealogical approach to suites of practices and their complementarity across productive domains (e.g. diverse crafts) provides insight into how broader political economic changes over the last millennium conditioned situated learning and knowledge transmission in relation to gendered social fields in the Banda area of Ghana. Drawing on data from the long-term Banda Research Project, I explore regional networks of learning and cultural transmission in relation to shifting contexts of predation and power associated with the transition from Saharan to Atlantic exchange. Using diverse lines of evidence, the paper asks how situated learning and knowledge transmission related to the shifting scales and topologies of social networks, as well as to performative engagements with a changing array of materials. Evidence for repetition, improvisation and affiliation in practices of potting and metal working provide insight into how communities of practice were produced, reproduced and reconfigured through these transitions. These ‘ways of doing’ were enmeshed in broader political economies and constellations of practice that may have been differentially experienced by their constituent members, with implications for the transmission of knowledge across generations and between regions.

[158] The Montezuma Baldcypress Record of Moisture Variability over Mesoamerica during the Past
Millennium

Megadrought has been implicated in pre-Conquest cultural development and decline at several pre-Hispanic city-states in Mesoamerica. However, the tree-ring record in Mesoamerica has not been long enough to extend back into the pre-Hispanic era to test hypotheses about climate and cultural change, or to help improve the dating of archaeological remains. We have developed four new tree-ring chronologies for Mesoamerica using ancient Montezuma baldcypress trees (Taxodium mucronatum) from the Rio Nazas and Rio San Pedro Mezquital, Durango, Barranca de Amealco, Queretaro, and Tzimol, Chiapas, which date from 1210–2008, 1075–2012, 771–2008, and 1280–2010 C.E., respectively. These chronologies have been used to reconstruct early growing season moisture conditions and indicate that the mid-12th century drought, the worst megadrought yet identified in the North America tree-ring record for the past 1200-years, extended into central Mexico and was approximately contemporaneous with the decline of the Toltec capital of Tula. The new reconstructions indicate profound drought during the early 15th rise of the Aztec state and during the Spanish Conquest of Mexico during the early 16th century. The Tzimol chronology has been used with a shorter chronology from the Rio Lagartero to reconstruct moisture variability over Chiapas and Guatemala for the past 500 years.

Staller, John (The Field Museum)

[150] Political Economy, Ideology, and Language in Ancient Ecuador: Regional Developmental Period (ca. 300 B.C.-A.D. 800)

The cultural and ideological integration of ancient Ecuador is associated with the spread of maize, Spondylus/Strombus shell artifacts, ceramic technology, and metallurgy in the context of long-distance interaction ca. 1400-300 B.C. Coastal and highland Ecuador were unified early on by vast networks of roads, that facilitated the spread of the Quechua and Aymara language families and economically unified vast highland and coastal regions. Multidisciplinary evidence from the Regional Developmental Period suggest language, religious ideology, and adaptation to the extreme Andean verticality were critical factors in the similarities and diversity of material and architectural responses and their mosaic of cultural expressions.

[146] Paracas Period Settlement Clusters in the Upper Chincha Valley, Peru.

Three seasons of survey and excavation reveal a complex pattern of linear geoglyphs and settlements in the upper Chincha Valley of coastal Peru. Excavations indicate that the settlements are largely Paracas in date. The data indicate that the Paracas period settlement pattern in this chaupiyungas area was characterized by clusters of platform mounds, ceremonial structures, habitation sites and associated geoglyphs. This pattern predates Nasca period geoglyphs typical of valleys to the south. These data provide new information on the context in which the geoglyph-building tradition in the south developed over time.

[174] Memorialization and Memory of Southern California’s St. Francis Dam Disaster of 1928.

In studying the interrelated themes of memory, materiality, and heritage, scholars have recently focused on how landscapes, monuments, and other mnemonic devices influence the formation and maintenance of public memory. Utilizing this approach, archaeologists can examine how memory is grounded in a local community and transmitted through society, revealing the role that landscapes and objects play in the construction of memory. Resulting in the 2nd largest loss of life in the state’s history, Southern California’s largely unheard-of St. Francis Dam Disaster of 1928 provides excellent circumstances for studying catastrophe and memory, and for looking at how political, economic, and social forces impact memorialization and processes of remembering and forgetting. This poster will explore how the disaster and the dead have been commemorated both physically and conceptually throughout the landscape of
the 54-mile flood zone, and will discuss the impact that failing to memorialize has had on the social memory of this catastrophic event.

Evaluating Formative Period Yaxuna through Monumental Architecture  
Recent research focused on the monumental groups of Yaxuna, Yucatan has shed light on the scale and nature of Formative Period public architecture at this early urban center. The current data indicate that this site was established around the ninth century B.C. and quickly grew into one of the largest Middle to Late Formative centers in the central northern lowlands. This paper specifically focuses on the dating of floor sequences in two of the acropolis groups located in the core of the site, as well as in the outlying Tzacaui Acropolis, a monumental group found three kilometers to the east of central Yaxuná, but connected to the core by a raised causeway. Finally, horizontal excavations conducted in the E-Group plaza are analyzed. The implications of these data are discussed in relation to early urbanism in the northern Maya lowlands and exchange relationships to Formative Period sites in Peten.

Stapleton, Charles (Northern Illinois University) [91]  
Teotihuacan Predatory Animal Imagery Revisited  
A rich and varied repertoire of feline, canine and raptorial bird representations have been found at the Classic-period site of Teotihuacan, Mexico and other related Mesoamerican sites. These painted and sculptural sources are often seen as direct referents to the phenomena of human heart-sacrifice and warfare. The unquestionable predatory prowess of these animals in their natural habitat and a significant body of literature support this set of interpretations in many contexts. However, this corpus also holds additional, largely untapped information that invites scholars to revisit and, in some cases, reconsider their original meaning and function. This paper will focus on alternate and recontextualized interpretations of this special subset of Teotihuacan iconography.

Stapleton, Charles [183] see Stapleton, Maria

Stapleton, Maria (Northern Illinois University) and Charles Stapleton (Northern Illinois University) [183]  
Tlaloc: Persistence of an Aztec Deity into Early Colonial Mexico  
Far from disappearing, some Late Postclassic images of Aztec deities survived the early Christian evangelization of central Mexico thanks to syncretism with the symbolism and function of important Christian figures. Despite widespread social and religious changes, the Aztec rain-god Tlaloc persisted in the ideology of Mesoamerican people. Figural representations of Tlaloc and associated cult practices gradually merged with those of a new symbolic figure, Christ, a personage of central importance in Christianity, became the recipient of the all qualities previously assigned to the Aztec god Tlaloc. The study of an early sixteenth-century maize-based crucifix brings to light the Mesoamerican transmigration of Tlaloc’s qualities and attributes into an officially accepted Christian figure. This holistic study supports claims for the continuity of pre-Hispanic beliefs and a hybridization of indigenous and Christian symbols in early colonial Mexico.

Stark, Barbara (Arizona State Univ) [281]  
Are You Being Served by Formal Mesoamerican Ballcourts?  
The social roles of the Mesoamerican ballgame have been examined through settlement patterns with success, revealing likely political and social mediation among polities or communities. But who could witness a game? Lines of sight toward the formal court from surrounding architecture at centers in south-central Veracruz yield an estimate of numbers of viewers. The court viewership is compared to public plaza assembly spaces to determine whether ballgame viewership was more restricted. Comparison of these values for primary and secondary centers addresses the consistency of social separations in the political hierarchy.

Climate Change, Human Population Growth, or Both? Upper Paleolithic Subsistence Shifts in
Southern Greece

Changes in subsistence patterns during the Upper Paleolithic and Mesolithic at Klissoura Cave 1 in southern Greece indicate that some shifts track local climatic changes, while others do not. Specifically, increases in ungulate species diversity correlate with wetter periods, and greater abundances of certain dry-loving small game animals (e.g., great bustard) correspond with dry periods. Other large-scale diachronic shifts, such as the increased importance of low-return small game animals (e.g., hares and partridges), occur over the occupation of the site irrespective of environmental conditions. It was hypothesized previously that this relates to local human population growth over the course of the Paleolithic. New data from a nearby site, Kephalari Cave, augment this hypothesis. The site complements the Aurignacian and Gravettoid occupations at Klissoura and also contains a robust late Upper Paleolithic component. Ungulate species diversity is high at Kephalari, and there is a greater reliance on low-return small animals (including fish) than at Klissoura. This presentation examines changes in the faunal spectra of the two sites in the context of regional environmental change in order to determine the extent to which climatic change or population growth were the driving forces in subsistence shifts in southern Greece during the Late Pleistocene.

[36] Landscape, Community, and Human-Environment Relationships in the Lake Pátzcuaro Basin, Michoacán, Mexico: Geospatial Analysis and the Late Postclassic Tarascan Empire

The Lake Patzcuaro Basin (LPB) in Michoacan, Mexico was the prehistoric core of the Tarascan Empire, a Late Postclassic state that existed contemporaneously with the Aztec Empire. Given the importance of archaeological research in this area, it is only natural that the field of Geographic Information Science (GIS) would find a suitable role, and complement the multiple areas of research and investigation into past human behavior. This paper examines the role of GIS and geospatial analysis in these archaeological investigations of the Tarascan Empire. Specifically, it focuses on the development of prehistoric communities, human-environment relationships, and the emergence of the Tarascan state. This includes the creation of several data sets in a GIS and the utilization of spatial analyses, such as cost surfaces, cost-distance modeling and interaction analysis, to provide two things: 1) an interpretive framework for understanding community formation and coupled human-environment systems that existed over a span of 1,300 years in the lake basin, and 2) the creation of "born digital" data from these geospatial analyses, which can then be used to expand our understanding of prehistoric state emergence in Western Mexico.

[46] Investigating the Dynamic Relationship between People and Turkey in the Pueblo Southwest: The Case Study of Sapawe’uinge

Ethnographic reports of Pueblo peoples from the twentieth century suggest the use of turkeys for food was taboo, except in rare cases; however some archaeological interpretations, regarding Ancestral Pueblo sites predating A.D. 1300, have cited turkeys as being an integral part of the Puebloan diet. This project seeks to understand if and when a change in turkey-use within Puebloan diets occurred in the late prehispanic or Historic period, and why this change may have occurred. To address these issues, I examine faunal remains from the ancestral Tewa site of Sapawe’uinge (LA 306) located in the Rio Chama watershed in northern New Mexico. Sapawe’uinge, which spans the Classic period (A.D. 1350–1600), is an ideal context for understanding Puebloan subsistence due to a long occupation ranging from Tewa coalescence to Spanish colonization, as well as the site’s history of extensive archaeological excavation. By sampling midden, room, and kiva contexts, I use indices to track proportions of turkey compared to proportions of other animals often associated with subsistence through the Protohistoric period. I then relate these results to broader trends in Pueblo-turkey relationships across the American Southwest.

[199] Review of Rock Art Dates for the Lower Pecos, TX
The Lower Pecos Canyonlands was the original study area for Rowe and his Texas A&M University chemistry laboratory when developing the plasma-chemical extraction technique to radiocarbon date rock paintings. Thirty-three radiocarbon dates from eleven different sites have been determined using plasma oxidation and AMS radiocarbon dating. For the Pecos River style, thirty dates from seventeen paintings at nine different sites have been reported. There are three additional radiocarbon assays: one for a Red Monochrome painting; one for a Red Linear painting; and one for an unclassified charcoal deer. While the Lower Pecos Canyonlands have been considered to be one of the best-dated rock art regions in the world, this review suggests that further research is needed.

Managua Polychrome: The Missing Link to Mesoamerica?

First described by Samuel Lothrop in Pottery of Costa Rica and Nicaragua (1926), the distinctive ceramic type Managua Polychrome has been largely neglected by archaeologists working in Pacific Nicaragua. Commonly identified as a minor local product of the Managua-Masaya region and generally excluded from the loose grouping of supposedly “Mesoamerican-influenced” ceramics often referred to as Nicoya polychromes, Managua Polychrome in fact seems to represent a direct analog of ceramic types found much further afield, including types associated with trading centres in Chiapas and northern Honduras that ethnohistorical accounts associate either with cultural groups indigenous to Nicaragua or with ethnic enclaves of Mesoamericans. This paper will provide a detailed description of the type and discuss some of the possible implications of its apparent links to Mexico and Honduras with respect to ongoing efforts to understand the arrival of Mesoamerican peoples in Pacific Nicaragua during the Postclassic Period.

Archaeobotanical Studies in the Central Coast of Peru. The Case of the Inca site of Panquilma and its Distribution, Consumption and Manipulation of Native Andean Plants

The excellent conservation of the vegetable remains at the Inca site of Panquilma has developed a new interest in the archaeological research on this site. The information about the distribution, consumption and manipulation of certain native plants can help us to understand the social inequality established among the different groups that occupied the site. The archaeobotanical research focused on the comparison of public and domesticate sectors (respectively sectors 1 and 2). Our aim was to try to discover if there existed a distinction between the access of some or all of the plants and the reason for this. In this communication, after a brief introduction to the archaeobotany, we are going to present independently the results of the analysis of archaeobotanical remains of both sectors. Then we are going to compare the conclusions of the two areas. Finally, this will allow us to present some preliminary conclusions on the socio-economic-political relationship between both sectors.

3D Imaging Technology and Multi-scalar Analysis of Stone Tools: Morphology, Reduction, and Use-wear

Recent advances in 3D imaging technology and better access to 3D printers provide archaeologists with powerful new tools for analyzing material culture and preserving and sharing information. In particular, lithic analysts have been drawn to this technology given its many potential applications for stone tools both in the field and in the lab. For this study, we took 3D images of experimentally used stone tools made from a variety of raw materials (chert, flint, glass, obsidian and quartzite) using a laser imager (reverse engineering model) to reproduce tool morphology and to test how such images may assist in reconstructing reduction techniques. Edge damage on these tools was also examined using the images to establish whether low-power use-wear analysis was possible. The precision and accuracy of tool
surface reproduction in the 3D images is evaluated in terms of analyses at multiple scales.

[240]  Feminist Communities of Practice in Archaeological Research and Teaching
Feminist archaeology is often conflated with gender archaeology, and as such, research and teaching in which gender does not appear to be the primary focus can be seen as being outside the scope of feminism. However feminism is relevant in all aspects of teaching and research because it is about practice and action. Regularly using intersectional approaches provides opportunities to bring feminist practice to everyday work. We will describe one area, Feminist Communities of Practice, where we see potential for the constant integration of theory and practice.

The obsidian hydration layer may be measured using a variety of technologies that include optical microscopy and hydrogen depth profiling by secondary ion mass spectroscopy (SIMS). Photoacoustic spectroscopy (PAS) is a third option which uses infrared energy to quantify the amount of ambient water that has diffused into the surface of the obsidian over time as well as the quantity of structural water contained within the non-hydrated glass structure. This latter variable is the primary determinant of the hydration rate. In the method developed here, the multiple water bands collected by PAS in the mid-infrared region provide the parameters necessary for the calculation of quantitative age estimates.

[70]  A New Approach for Calculation of MNI in Commingled Remains: Mortuary Analysis of Caves Branch Rockshelter, Belize
Excavations at Caves Branch Rockshelter in the Caves Branch River valley, Belize have revealed a mortuary population spanning the Classic period. Individuals of both sexes and all age groups were represented in the mortuary sample. Like many other cave and rockshelter sites, extensive looting and repeated intrusive burials has created a matrix of highly fragmented and commingled bones. This taphonomic history severely hampers estimates of the minimum number of individuals (MNI) and the
reconstructions of mortuary rituals in caves and rockshelters. Using a new coding system to identify overlapping bone features, a digital inventory of skeletal remains was created in attempt to ascertain an accurate MNI for the Caves Branch sample. This new technique offers a more systematic way of determining MNI of burial populations when preservation and contexts are not ideal and can be applied to a myriad of poor mortuary situations.

[246] Viewing Cultural Landscapes in the Long and Short Term

Mike Jochim’s view of archaeology as long-term ethnography, with all manner of variation in year to year practices, has provided a call to focus our attention equally on ephemeral as well as large, stratified sites. Investigating variation in behavior requires analysis using techniques like GIS and simulation, in order to achieve more than simply coarse-grained generalizations. In the recent settlement records of the Canadian Arctic and Subarctic, we think we have access to a relatively fine-grained record due, in part, to favourable conditions for preservation and visibility, but also access to informant histories. Sites representing a wide range of behavior and scale of activity are represented across these landscapes. Individual as well as aggregate responses to environmental challenges and opportunities are in some manner accessible through the combination of the archaeological, documentary and oral history records. How has this favourable circumstance informed our understanding of how cultural landscapes evolve; and what is the relationship of these landscapes to individual or small-group behavior?

[328] Terror in the Desert

Since the early 1990s, the American policy along the U.S./Mexican border has explicitly used geography as a tool to deter and punish undocumented migration. Extreme environments, such as the Sonoran desert, have been left un-walled, with the intention that the harsh environment will be too painful to cross. Contrary to this assessment, over this period millions of migrants have made this crossing. At the same time, due to the harshness of the area, thousands have died. Since 2008, the Undocumented Migration Project (UMP) has used traditional archaeological techniques to find, map, and analyze the trails these migrants have used over the past fifteen years through the artifacts they have left behind. Using data collected by the UMP this paper attempts to show how American border policy has increasingly pushed migrants into crossing through increasingly remote and dangerous areas. More specifically, this paper will discuss how the Department of Homeland security has transformed the desert into a weapon for border containment, and how this weaponization is indexed in the material record. Over the past fifteen years, this record shows increasing levels of migrant injuries, increasing use of painkillers and bandages, and ultimately, increasing numbers of migrant deaths.

[245] Surf and Turf: Maritime and Agrarian Economies at the Early Horizon Center of Caylán, Nepeña Valley, Coastal Ancash

This paper explores the relationships between Andean coastal adaptations and processes of developing social complexity as viewed through the processing, consumption and discard activities related to maritime and terrestrial resources at the center of Caylán. This large urban settlement developed in the coastal portion of the Nepeña Valley, Ancash (Peru) during the Early Horizon. We integrate various lines of evidence including animal remains, macrobotanics, soil samples, coprolites, and material culture to shed light on local practices. In Nepeña, the Early Horizon marked an expansion of agrarian practices, and a continuing reliance on marine resources as common foodstuffs and raw materials. We adopt a multiscalar approach from the regional to the local, and focus on the contexts of process, consumption, and discard of different types of resources in order to understand the combined, dynamic meanings of maritime and terrestrial economies. In particular, we aim at going beyond the traditional cultural ecological debates to focus on the social and political aspects of exploitation and management of coastal resources in the context of incipient urbanism.

Finding a common band-width: Causes of convergence and diversity in Paleolithic beads

Ornaments are the most ubiquitous art form of the Late Pleistocene. This fact suggests a common, fundamental function somewhat different to other kinds of Paleolithic art. While the capacity for artistic expression could be considerably older than the record of preserved (durable) art would suggest, beads signal a novel development in the efficiency and flexibility of visual communication technology. The UP was a period of considerable regional differentiation in material culture, yet there is remarkable consistency in the dominant shapes and sizes of Paleolithic beads over >25,000 years and across vast stretches of space, even though they were crafted from diverse materials and, in the case of mollusc shells, diverse taxonomic families. Cultural and linguistic continuity cannot explain the meta-pattern. The evidence indicates that widespread adoption of beads was not only about local and sub-regional communication of personal identity or group affinity, but also an expansion in the geographic scale of social networks. The obsession with rounded basket-shaped shells in particular related in part to their light weight, wearing comfort, and visual attractiveness. The conformity of the beads grew spontaneously, in a self-organizing manner from individuals’ interest in tapping into the network as a means for managing local risk.

Calf Creek in Kansas: The Northwestern Frontier

Mid-Holocene Calf Creek sites are well documented in Arkansas, Missouri, Texas, and Oklahoma, but less so in Kansas, where most Calf Creek points are surface or creek-bed finds. However, recent studies from a stratified multi-component site, 14CW402 (Site 98), and another site that likely is stratified, 14CO120 (Grouse Creek), provide new data on the Calf Creek complex for southeast Kansas. This paper presents information on the known distribution and nature of Calf Creek sites in Kansas, data on toolstone sources and their significance, relationships to other regional archaeological manifestations, the environmental and geomorphological settings of the sites, and the effects of the Altithermal climatic episode on human activity and site preservation.

Stockett Suri, Miranda (Queens College)

Archaeology Should Be Able to Adapt

Archaeology has frequently been accused of losing its relevance—a problem which has only worsened in the years since I earned my Ph.D. and joined the ranks of working archaeologists. A lack of adaptability within the discipline and among its practitioners is a major source of this problem. We cling to the past represented by our teachers and mentors who worked in an era that bears little resemblance to the academic, political, and cultural climate of today. The tenure track positions they enjoyed are an unattainable dream for most archaeologists of my generation, teaching and education are increasingly devalued, and multi-year, big budget field projects are less and less tenable due to funding cuts and political instability in our regions of study. While most are willing to acknowledge these problems, we seem paralyzed when it comes to solving them. It is my hope that collectives, such as the one convened for the purposes of this session, may collaboratively tackle these challenges—both ideologically and practically. In short, I argue that archaeology and archaeologists must adapt to today's academic and political realities if we wish to escape obsolescence.

Stöckli, Matthias (Dep. de Antropología y Sociología, Universidad del Valle de Guatemala)

References to Sound in the Rabinal Achi, Guatemala

Alphabetic texts written by Mayan authors after the Spanish conquest contain quite a few references to the production, perception, and conceptualization of musical as well as non musical, human-made as well as natural sounds in pre-Columbian times. Such a text, originating in the Guatemalan highlands, is the Rabinal Achi, a dance-drama still performed today and therefore especially rich a musicological object of study as it consists of both actual sounds and textual references to them. In this and other colonial documents human-made vocal or instrumental sounds are often related to political power, war, and sacrifice. Again, this becomes especially clear in the Rabinal Achi where one of the protagonists has not only several sets of musical regalia to call his own but, after being captured in war and certain of his immediate death by sacrifice, also ascribes to their sounds a life-transcending power. The focus of this presentation is on those sounds and their meanings.

[247] Violent Death, Social Memory, and the Nature of Persistent Places
The role of violence in the abandonment of communities in the northern Southwest is a topic of much discussion among archaeologists and bioarchaeologists. Recent advances in behavioral taphonomy and the integration of meticulously detailed site and oral histories enhance our understanding of the processes that precipitated episodes of violence, and the phenomenological aspects of the events themselves. In this paper, I approach the long view of the impact of one of these events, the massacre at Sacred Ridge, and explore the implications for the social and spiritual history of the survivors and perpetrators, and for the nature of Ridges Basin as a historical place in social memory. If burials are a critical aspect of persistent place as the dead continue to occupy their communities, then what kind of persistent place is created by a massacre?

[303] The Utility of Intra-Community Approaches in Bioarchaeology
Bioarchaeology has developed along two independent tracks that determine research approach. Osteobiography provides a combined humanistic and forensic approach that individualizes the past, while population level analyses are more concerned with top down inferences about population affinity, demography, and health in which the individual is often minimized. Mortuary analysis can bridge these distinct research approaches by developing sampling concepts above the individual but below the community level. In this paper I present spatial analyses of phenotypic variation and data on health and diet from two 17th century Spanish mission churches. Methods are presented for identifying kin groups and documenting spatially relevant patterns of disease profiles among graves. The purpose is to demonstrate how the identification of sample groups at the intra-community level can inform inferences of health and diet that are more directly relatable to broader concepts of economic and social inequality. In addition, I discuss the relevance of identifying single interment events for informing the osteological paradox and looking for co-morbid conditions that reflect short term community stressors which may selectively affect certain segments of the population. Both case studies are contrasted with more standard population level approaches in which the site forms the basic unit of analysis.

Stokes, Robert
Emil Haury’s pioneering work at the Harris Site in the 1930s helped to establish the Mogollon culture and formed the framework for Mogollon pottery typology. San Francisco Red, Mogollon Red-on-brown, Three Circle Red-on-white, and Mimbres Boldface became diagnostic cultural markers for the Mogollon and the cornerstone for cross-serialization, useful for dating structures and sites. Although spatial, temporal, and production attribute refinements have been made to this basic typology since then, especially within the black-on-white series, the framework and underlying sociocultural and production assumptions behind it remain largely unchanged: the Pithouse period Mogollon were a localized and somewhat insular group who lacked a larger socioeconomic exchange network characteristic of the later Pueblo period groups. However, recent research at the Harris Site by the University of Nevada-Las Vegas is beginning to demonstrate that the Pithouse period Mogollon in the Mimbres region were far more sophisticated culturally, socially, and economically than previously suspected, and, as the recent ceramic analysis results suggest, maintained a strong, vibrant connection to northern, northwestern, and western groups who produced Cibola White wares and early southern Hohokam pottery. Thus, this paper presents new ceramic data that update our understanding of the cosmopolitan world of the Pithouse period Mogollon.

**[91]  The Ballgame Traditions of Prehispanic Oaxaca**

The ballgame has a long and profound history in both Oaxaca and Mesoamerica. Archaeological evidence indicates that the game was played in the Oaxacan region by the Middle Formative period, and that masonry courts appeared soon after in the Late Formative. Yet the evidence also suggests that the ballgame tradition in Oaxaca is distinct from other regions in Mesoamerica, and may in fact have had multiple traditions present throughout the Prehispanic era. In this paper, I analyze the archaeological, ethnographic and iconographic sources on the ballcourts and ballgame itself to identify the similarities and differences between different ballplaying regions of Mesoamerica. I also critically evaluate the role both the ballcourts and ballgame played in Prehispanic inter-community sociopolitical relationships, and how this role may have varied through time and by region, focusing specifically on Oaxaca. Finally, I present new research on the recently discovered ballcourts in the Nejapa Valley region of eastern Oaxaca. A multiethnic zone both in the past and today, the Nejapa Valley region may have much to tell us about the ballgame tradition within a specific regional and historical context.

**[126]  Maternal Health: The Pelvis and Embodied Social and Political Stress**

Early death for females has long been tied to poor maternal health and complications at birth within archaeological studies. But what do we really know about maternal health and obstetric death in ancient populations’ and what have we assumed? This paper examines pelvic and occupational stress data from a number of Ancestral Pueblo skeletal populations to move beyond static assessments of obstetrical death for females by understanding skeletal patterns of stress for reproductive aged females and what can be revealed about the social and political contexts of their lived experiences beyond maternity. Skeletal data is framed within ethnographic and archaeological contexts for Puebloan females to frame daily life (occupational stress) and maternal stressors. These data juxtaposed with recent research, strongly suggests that parturition exacerbates the lived experiences of pain and suffering women face. Thus understanding female’s roles in community and the structural frameworks (systems of belief, division of labor, structural violence, etc.) that result in a lifetime of embodied trauma and illness are now coming into focus. This new thinking suggests that poor maternal health and death is more of a litmus test to the larger issues females face, and this should be considered as we examine the past.

**Stone, Abigail (Washington University in St. Louis)**

**[205]  Feeding an African City: Mobility, Pastoralism, and the Development of Urbanism in Mali’s Inland Niger Delta**

This paper investigates the relationship between nomadic pastoralists and urban populations, presenting a case study of a complex, non-hierarchical relationship between mobile and sedentary populations in Mali's Inland Niger Delta (IND). The ancient city Jenne-jeno (occupied ca. 250 B.C.E. – C.E. 1400) plays a pivotal role in understanding West Africa's archaeological past and challenges conceptions of the relationship between hierarchical social structures and the development of urbanism. Until recently however, little was known about the broader Jenne-jeno urban cluster (>300 sites within 30km) or the role of mobile populations in the urban system. Drawing on four months of excavation at Tato a Sanouna and Thiel, two small sites in the urban cluster, and upon serial, intra-tooth isotopic analysis (87Sr/86Sr, δ13C, δ18O) of cattle, sheep, and goat teeth, this analysis suggests that rather than relying on a single system of mobile pastoralists sustaining a sedentary urban population, the IND population used a diverse system of local and seasonally mobile husbandry as well as import of non-local animals. These findings both corroborate and complicate previous interpretations of urban development in the IND and provide the first concrete evidence of the role of mobile populations in the Jenne-jeno urban system.

**[298]  Demography at the Chelechol ra Orrak Cemetery, Republic of Palau**

The Chelechol ra Orrak cemetery in the Republic of Palau contains one of the oldest (ca. 1700-3000 BP) and largest human skeletal assemblages in Remote Oceania. To date, elements representing a minimum of 40 individuals, including 12 articulated burials have been excavated. In an effort to better understand the life stresses impacting these early inhabitants of the archipelago, we have produced a demographic profile of the individuals represented in this death assemblage. Sex was determined for each identified and numbered individual using a combination of pelvic and cranial traits, while age was determined using epiphyseal union, tooth wear, and pelvic traits. Although there is a slight male bias (7-5) among the
articulated burials, the sexes appear to be equally represented when all skeletal remains are included. Elements have been recovered that represent individuals ranging from prenatal to middle adulthood, with at least 25 percent being younger than mid-teens. Average age at death appears to be relatively young, with the majority of numbered burials being late teens to early 30s with only one aged 40 or greater. Unlike some other cemeteries in Remote Oceania, underrepresentation of younger individuals or females does not appear to be a factor at Chelechol ra Orrak.

Stoner, Wesley (University of Missouri Research Reactor)

Research in the Classic Tuxtla Mountains of southern Veracruz Mexico has focused greatly on Matacapan and its connection to Teotihuacan. This disproportionate focus has skewed our view of cultural adaptations in the region. Recent studies at two other major centers in the region, Totocapan and Teotepec, suggest that Matacapan was not a typical representation of Classic Tuxtlas culture. The three centers were contemporaneous, and comparable in size and monumentality, but Totocapan and Teotepec did not share Matacapan’s use of central Mexican symbols. The three settlements appear to have been capitals of sovereign polities. I present an evaluation of political, cultural, and economic boundaries using a combination of GIS modeling and qualitative characterization. All three boundaries are characterized using a general model of boundary dynamics featuring seven variables designed to characterize the nature of cultural and economic interaction among the three polities. In the Tuxtlas case, the three discreet polities engaged in ceramic and obsidian exchange and some sharing of material culture styles. Other cultural traits, such as those adopted from Teotihuacan, were not shared across political boundaries. The boundary zone between Matacapan and Totocapan, however, displays a blend of economic and cultural influence from both polities.

Stoner, Edward (Western Cultural Resource Management, Inc.)

In my Master’s thesis, I told a story of a male hunting group who quarried chert nodules from limestone, reduced these into large bifaces, and took them to a nearby site in which they were heat treated. In gearing up for the hunt, the men detached flaked of suitable size and shape from the heat treated cores and made Rosegate preforms and arrow points. They maintained their workshop and cached thousands of heat treated flakes. Nowhere in my story, however, did I mention child quarries or flint knappers. This is remarkable given the sites might have been perfect classrooms for a novice to acquire those skills in an environment in which lithic raw materials were accessible, abundant, and expendable. In this paper, I reassess existing lithic data sets including the subjective and objective measures of artifact quality, attention to raw material selection, and discard patterns from the Quarry (26WP2418) and the Rosegate Site (26WP4629) and identify the material by-products of novice activities. The identification of children in the archaeological record has the potential to tell a different story of site demography and function; one that is both engendering and inclusive of the social contexts of learning.

Storey, Rebecca (University of Houston) and Randolph Widmer (University of Houston)

The skeletons from Tlajinga 33 have high prevalence of skeletal indicators of morbidity. Since this was a lower-status compound of artisans, this could be due to poor diet, as well as an unhygienic environment. Analysis of faunal remains suggests that animal remains were an important and plentiful component of the diet. However, most consist of insects, small fish, reptiles, avian eggs, and small mammals. Of particular importance is the size and nature of these dietary items, as many would be considered vermin which could be incidental in grains. It is important to employ proper recovery techniques to eliminate bias in size and nature of animal remains to obtain an accurate understanding of the total diet. We demonstrate that there was adequate animal protein in the Tlajinga 33 diet but that it was very different than what is usually considered “animal protein.” Thus, the residents had access to a nutritious and balanced diet, and this information eliminates protein deficiency as cause of the morbidity. Instead, the focus is on the urban environment and any status disadvantages faced by residents dependent on market exchange for staple foods. Food at Teotihuacan was more likely affected by social inequality than by availability.

[51] The Middle Kingdom Makes Itself: Archaeology of a Built Environment

The current period of industrialization in Chinese society is often thought of as a modern phenomenon. However, Chinese states have experienced periods of rapid growth before. During many Chinese dynasties population growth resulted in an increased demand for resources and goods, spurring the need for water management projects, extensive mining and smelting operations, and new agricultural technologies. To place the modern period of industrialization in historical context, an integrative archaeological approach is required. Historical documents, archaeological method, and geoarchaeological data are used in combination to explore past land-use histories, as well as assess the extent and type of environmental impact societies have on natural environmental conditions. Recent geoarchaeological work in Neihuang city, Henan province, China, highlights this approach. Using a deep sedimentary record, archaeological sites, and available historical documents, we attempt to reconstruct a land-use history for the study region to contextualize processes operating in the present but at a much larger scale.

[150] Multiple Lines of Evidence: Exploring diversity within the consolidation of the Late Intermediate Period in northern Chile.

The Late Intermediate Period in the San Pedro de Atacama and Río Salado subregions of northern Chile reflects many processes of similarity and difference. Architecturally, defensive settlements were built in both regions at this time. New ceramic styles are shared by both areas while burial practices, in turn, diverge. Each area displayed different amounts of nonlocal material culture in local graves, prompting authors to suggest the increased presence of individuals or cultural influence from southern Bolivia during the latter half of the period. Bioarchaeological work to date, however, belies proposed incursions from elsewhere. This paper employs ceramic evidence, mortuary analysis, and measures of biodistance based on cranial nonmetric traits to explore these coeval processes of cultural convergence and biological diversity. This juxtaposition falls in line with other local studies that show that complex material behavior was deployed in contrast to biological origin throughout prehistory. This study, therefore, breaks down the monolithic homogeneous regional cultures of the Middle Period and questions and contextualizes the ethnic fragmentation that is purported to have characterized the Late Intermediate.

[175] Measuring the Matrix II: Elemental Characterization of Sediments from HP 6, Slocan Narrows Housepit Village, British Columbia, Canada

Housepit 6 (HP6), an unusually large pithouse situated in a prehistoric village on the Slocan River in southeastern British Columbia, Canada, was home to hunter-gatherers approximately 2700 B.P. This unique dwelling holds the possibility of increasing our archaeological understanding of social organization among hunting and gathering societies in the Pacific Northwest. We examine evidence collected during the 2013 field season at Slocan Narrows from HP6 with the intention of developing insights into how the inhabitants organized themselves spatially. This project focuses on the elemental composition of sediment samples (n = 100) taken from floor and feature contexts within HP6. We prepared the samples and then analyzed them through EDXRF and WDXRF to detect potential chemical signatures of activity areas within the house. We also examined the spatial relationships of features found in, and artifacts collected from, HP6 to results of the elemental analysis. By identifying use-areas, hypotheses can be constructed about the potential social organization of HP6.

[137] Settlement Pattern Analysis at the Medicinal Trail Community, Northwestern Belize: Results of Total Station Mapping of the 2013 Season

This poster presents the results of the most recent season of total station mapping at the Medicinal Trail
Community, a Maya hinterland settlement in northwestern Belize, and integrates it with previous mapping data. Mapping during the summer of 2013 has refined our understanding of the size and distribution of households and numerous landscape features that have been, or continue to be, the focus of excavations. Refinements to total station mapping within the area has revealed (a) the largest, and most complex household groups are associated with ridge tops, (b) possible artificial drainages and reservoirs are associated with dense settlement, and (c) numerous terraces are located on the slopes of the ridges, near some of the drainage features.

[157] Advanced 3D Visualisation Workflows for GPR Archaeological Prospection Data: Case Studies from Ancient and Contemporary Urban Environments

The interpretation of GPR data is usually done on two-dimensional time slices or two-dimensional radargrams. This approach is suitable for simple archaeological contexts. However, when we are dealing with more complex contexts, multiphase approaches should be adopted to achieve a better understanding of buried deposits. GPR datasets collected in ancient and contemporary urban environments have been chosen to test the efficiency of the interpretation in a 3D environment and to compare it with 2D and 2D½ visualization of results.

[246] Magdalenian Settlement-Subsistence Systems in Cantabrian Spain

As closely influenced by Jochim's life-work in the field, this paper describes human adaptations to the environments of the late Last Glacial in Cantabrian Spain. Based on excavations in El Miron Cave in the Cantabrian Cordillera, and on analyses of data from other sites in the Ason River basin, as well as from excavations of Magdalenian (20-13k cal BP) sites throughout this narrow, high-relief, coastal region, it evaluates hypotheses proposing 1. valley-centered local band territories with short, seasonal movements between hub sites near the coast and others in the mountains; 2. local collection of food resources (notably red deer, ibex, salmon) within hub site catchment areas; 3. specialized camps, particularly montane loci for ibex hunting; 4. procurement of non-local, high-quality flints via travel to sources beyond the local valley or inter-group exchange; 5. participation in social networks beyond the Cantabrian region to include the French Pyrenees as manifested in cave and portable art. The data on faunas, lithics, site locations and structures make this one of the richest records for the last few millenia of the Pleistocene and a key source area in the recolonization of northern Europe by humans and other species after the "refugium" period of the LGM.

[60] Maintaining Soil Quality in Irrigated and Dryland Agricultural Fields: A Comparative Study of Upland and Lowland Environmental Impacts in the Hohokam Region in the U.S. Southwest

Farmers in arid environments across the world use a variety of strategies to bring water to their agricultural fields, including both irrigation from perennial rivers and constructing infrastructure, like checkdams, to divert runoff to dryland fields. These two different agricultural strategies can vary quite a bit in their impacts on soil quality. The Hohokam of southern Arizona are famous for their large-scale irrigated agricultural systems, which fed water to thousands of hectares of agricultural fields throughout the lowland valleys of southern Arizona, but also used upland regions to grow crops in rainfed fields. Both irrigated and dryland agricultural fields in the Phoenix Basin have been little studied, although researchers often hypothesize that problems within those fields, including salinization and flooding, may have led to the depopulation of the region in the mid AD 1400s. This paper will present results from large-scale soil sampling of irrigated fields from the Phoenix Basin and evaluates the impacts of long-term irrigation farming on soil quality within agricultural fields. It will also assess pilot data from soils from upland dry farmed fields and compare how the Hohokam may have used and impacted both lowland and upland agricultural areas differently in the past.

[182] I Saw the Sign: A Comparative Analysis of Warfare Indicators in Ethnographic and Archaeological
Cases
The majority of societies have at some time participated in a form of warfare. Even so, direct archaeological evidence of warfare, such as battle-related injuries and deaths, is often sparse. Archaeologists therefore often turn to comparative ethnographic research to identify other material indicators of warfare. This work has produced a suite of attributes often associated with warfare, such as defensive site locations, investment in defensive fortifications, and violent imagery, which forms the basis of many warfare models. Despite widespread use of these indicators, there has been little exploration of alternative or evolving explanations for the presence of such indicators. In this paper, we examine the relationship between suggested indicators of warfare and the archaeological record. By comparing cases from the Eastern Woodlands and the Southwest, we will examine the level of correspondence between attributes suggestive of warfare and the archaeological context in which they arise. We will then compare each case to the other cases to see if such attributes are present across the cases in similar contexts, or if their possible meaning is context specific. This work explores whether the attributes currently attributed to warfare provide adequate general insights, or if they are more valuable for understanding particular instances.

[196] Increasing the Effectiveness of GPR Mapping for Unmarked Burials: A Processing and Analysis Approach

Situations involving unmarked human burials are sadly common, incredibly complex, and often emotionally-charged. Ground-penetrating radar (GPR) is arguably still the single most effective method to locate and map unmarked burials in a non-invasive way. Yet despite many years of proven success in a variety of contexts, the use of GPR to locate and map unmarked burials remains uneven and misunderstood. I argue here that a large part of the confusion surrounding GPR in cemetery contexts can be attributed to the way GPR data are processed and displayed. In other words, both users and consumers of GPR data have come to expect the instant gratification through clear, “x-marks-the-spot” slice-maps, and lacking these, often deem these surveys “failures” prematurely. I argue that any GPR survey, and particularly those involving situations as complex as cemeteries, benefits from a varied data processing strategy and more nuanced approach to data analysis. This presentation draws upon examples from cemetery surveys around the U.S. that might have been considered “failures” had a first-pass processing attempt been dubbed sufficient. It seeks both to address common confusion with data processing and map display, and offer solutions for using these data in productive ways.

[69] The Early Peopling of the Uruguay Middle River: New Data, Recent Advances and Perspectives

Uruguay are known in academic circles by the classic Fishtail points, which have been until recently used as practically the only evidence of early settlement in the country. Systematic research to investigate the early human occupation in the North of Uruguay has been undertaken since 2000. The aims of this presentation are analyze developments of Uruguayan new data during the last 14 years of research related to the peopling of South America. Among the principal data we recorded an interesting cultural variability in different designs of projectile points: Fishtail points (ca. 13,000-12,500 yr cal B.P.), K87 Tigre points (ca. 12,280-11,200 yr cal B.P.) and Pay Paso points (10,900-9500 yr cal B.P.). In this paper I explore three major topics. First, Atlantic coast and Uruguay River as a human entry route or way for the exploration of the Southeast of South America. Second, the mobility and territory used by the different groups. Finally, I compare and discuss the Uruguayan data with those of nearby regions such as Pampa (Argentina) and Southern of Brazil.

Cholula y su paisaje. La utilización del paisaje cultural en la conformación de los calendarios de horizonte.

Cholula es conocida en el mundo por su Gran Pirámide, por su vocación religiosa y comercial, y por su hermosa cerámica policroma. Si investigamos un poco más, veremos que también se distingue por su estilo arquitectónico, pues muestra su independencia y creatividad con relación a Teotihuacán. Sin embargo existe algo que apenas se está investigado con mayor detalle, pues salvo algunas observaciones que hiciera Tichy (1976 y 1978), en donde reconoce a la ciudad y a su “pirámide solsticial” como el eje rector a partir del cual se orientaron los campos de cultivo, iglesias y asentamientos vecinos, registrando una desviación del basamento de 26° con respecto al norte, que permite, entre otras cosas, que la estructura quede alineada con la salida del sol el 21 de diciembre, y los reportes de Marquina (1975:117), quien agrega que los altares oriente y poniente están orientados con el paso cenital, poco se ha investigado sobre la utilización del paisaje oriente y poniente que se observa desde la Gran Pirámide y que proponemos fue utilizado para estructurar su calendario de horizonte.

Geochemical Composition of Obsidian from the Shirataki Source, Hokkaido, Northern Japan: Inter-laboratory Check and Its Consequence

The aims of the present study are to: (1) compare the results of quantitative analysis among independent laboratories, and (2) establish obsidian geochemical reference standards, and 3) compile the quantitative values for the Shirataki obsidian source. Four obsidians from different geologic sites were selected for this study. These were named JOSH-1, JOSA-1, JOO-1 and JOR-1 after the locations of the obsidian outcrops (Hachigosawa, Ajisai-notaki, Oketo and Rubeshibe, respectively). A variety of analytical techniques were used including the EPMA, WDXRF, ICP-MS, NAA and PGAA analyses. The EPMA analysis stands to examine the chemical homogeneity and the petrology of the samples. Other methods serve to determine the whole-rock element concentration in the samples. In this presentation, we first detail the occurrence and petrology of the obsidian. Next, the results of data compilation and their geochemical characteristics are presented. Finally, the utilization of common standards will be proposed.

Phytoliths and Paleosols of Calf Creek Times

With radiocarbon dates ranging from 4900 to nearly 5500 years ago, the Calf Creek cultural complex in Oklahoma, Kansas, and Texas appears associated with a brief interval of ameliorated climate on the Southern Plains. To better understand the nature of this climate and its effects on vegetation and landscape stability, I report the phytolith signatures incrementally recovered from four buried soils believed to correlate with the Calf Creek cultural complex. Two of these paleosols are in the uplands of northwestern Oklahoma, one is from a small watershed in central Oklahoma, and the fourth is from a tributary to the Verdigris River in the Cherokee Prairie region of northeastern Oklahoma. Calf Creek artifacts have been found near each of these paleosol localities, so the phytolith data are believed to attest directly to ecological conditions when these middle Holocene hunter-gatherers roamed the region.

Sugiyama, Nawa (Harvard University)

Faunal Acquisition, Maintenance, and Consumption: How the Teotihuacanos Got Their Meat

Understanding the role of vertebrates in Mesoamerican food systems has often been misunderstood due to the lack of large domesticated livestock that was at the center of Old World subsistence economies. This paper investigates the zooarchaeological record from one of the largest urban centers of the New World at the site of Teotihuacan, to understand the contribution of fauna to their diet. Within this arid highland ecosystem, the process of faunal acquisition, maintenance and consumption is investigated within the context of abundant archaeological, environmental, ethno-historic and ethnographic record to understand the mosaic nature of the Teotihuacan faunal economy. Such evidence is utilized to create a model of household-level management systems that tapped into the diverse local landscape. Furthermore, this system was supplemented by a market economy that imported exotic fauna.
many animals were not fully domesticated, they were often managed, tamed and controlled to create highly interdependent relationships between the local landscape and the growing human population.

[279] The Nature of Early Urbanism in Teotihuacan
I characterize the process of incipient urbanization during Late Preclassic Teotihuacan (A.D. 1 to 300). The city of Teotihuacan was created rather suddenly to an unprecedented scale around the first century A.D., developing the unique city layout and distinctive architecture style seen today by the 3rd century. I focus on materials corresponding to this foundation period: earlier structures disclosed inside the Moon Pyramid, those found recently in the Sun Pyramid, and remains existed in pre-Citadel periods. I also analyze symbolic objects found in relation to these earlier structures that suggest strong concerns on materializing their innovative worldview and related astronomy/calendar complex. In order to compare or integrate these monuments I re-interpret the symbolic city layout and modification/enlargement programs using newly created 3D architectural and topographic maps. I discuss city orientations, symmetrical/proportional spatial distribution and dimensions of the monumental zone applying my Teotihuacan measurement unit study. I tentatively propose “districts” that functioned along the Avenue of the Dead and the possible meanings encoded in early city formation. It seems urbanism in early phases at Teotihuacan developed along with innovative cosmological ideas, powerful rulership with highly organized political/military institutions that probably triggered population growth, economic activities, social hierarchy, and political conflicts.

[120] The Spectacular Polity: The Evolution of Ceremonial Practice and Political Authority from the Middle Formative through Late Formative Periods in the Chiapas Central Depression, Chiapas, Mexico.

From the Middle to the Late Formative period in the Chiapas Central Depression the layout of civic-ceremonial spaces changed substantially, from sprawling plazas, suggestive of public processional ceremonies, to increasingly smaller and less visible spaces, suggestive of more restricted ceremonial practices and a narrower intended audience. In this paper I analyze changes in the organization and use of civic ceremonial space at political centers in the Chiapas Central Depression and the implications of these changes on relationships between rulers and ruled. I also explore the notion that changing conceptions of ceremony and rulership were linked to geopolitical shifts that accompanied the decline of the Gulf Coast Olmec polity of La Venta and the concurrent rise of Lowland Maya political centers.

[157] Revealing Architectural Variation through Near-surface Geophysical Survey at a Multi-mound Civic Ceremonial Site in Northwest Arkansas
Sporadic archaeological investigations have revealed little about the breadth of architectural variation that existed among pre-colonial, aboriginal societies in the Western Ozark Highland region. The results of recent near-surface geophysical survey at the Collins Site, a possible Early and Middle Mississippian period (ca. A.D. 900-1400) multi-mound site in Northwest Arkansas, suggest that geophysical survey is an efficacious method for investigating architectural distribution and variation on a landscape level in the Ozark Highlands. Magnetic gradiometry and ground-penetrating radar yielded a preliminary view of the distribution of architectural features at the site including mound-top enclosures and a number of off-mound rectangular and possible circular structures. A comparison of the characteristics of the geophysical anomalies identified at the Collins site with features excavated at other sites in the Ozark Highlands support the interpretation of the Collins site as a paramount mound complex associated with ritual mortuary events. Because excavation is not permitted at the Collins site, the use of near-surface geophysical survey is vital to the understanding of the site within the archaeological context of the region. In addition, the work exemplifies the importance of the role of geophysical technologies in the field of archaeology.

[292] Connecting the Dots: Colha, Kichpanha, and Maax Na, Preclassic to Late Classic Interactions

Drawing on data collected in northern and northwestern Belize, this paper will examine how the interdependency between different Maya communities varies over time based on changing access to resources and the political landscape. Several broad generalizations can be posited from research in the northern Belize region. In order to achieve a complete picture of how sites interacted with one another - local and regional processes will be considered. Ceramic and other data indicate that the widespread regional exchange networks used by emerging elite groups to consolidate power in the Preclassic shrinks during the Classic period when more local autonomy and organization is observed. Data recorded from the ancient Maya sites of Colha, Kichpanha, and Maax Na, as well as settlements near these centers, are utilized in this analysis.

[156] A Mammoth Mistake: Datura Moth Imagery at the Bluff Petroglyph Site, Utah

Researchers have proposed that a petroglyph panel near Bluff, Utah, includes depictions of two mammoths. While mammoths and other Pleistocene fauna are common in European rock art, no convincing examples have been identified in the Americas. This analysis brings to bear a combination of geomorphology, zoology, ethnography, and archaeology and concludes that the petroglyphs are not mammoths, but hawk moths or sphinx moths in various stages of metamorphosis. The attributes of the animals depicted are more consistent with these moths than with mammoths. Further, the rock surface on which the petroglyphs are made was not exposed until after the mammoth went extinct in the region. Ethnographic research indicates that this moth, which pollinates datura, was important in Southwestern religion and iconography.

[231] Different Assemblages, Same People? Comparing Métis Wintering Site Assemblages on the Canadian Prairies

Relationships between artifact assemblages and cultural identities are complex and difficult to disentangle. The Canadian west during the 1800s provides an interesting historical and archaeological case study that has potential to shed light on the dynamics of settlement, material culture, and the process of identification. During the early to mid-1800s, a set of cultural identities emerged from historical processes of contact to form a new peoples: the Métis. Based originally in the Red River Settlement, some of the Métis began to expand west after 1845, forming interconnected wintering communities to participate in winter bison hunting. These wintering communities were almost entirely inhabited by Métis families, so the assemblages from wintering sites present a test case to examine the material culture(s) of the Métis during the mid- to late-1800s. In this poster, we present results from previous and new excavations of Métis wintering sites in Alberta and Saskatchewan. We compare assemblages across sites and make inferences about the complex nature of Métis identities during the nineteenth century.

[16] Mobility at the Scale of Meters

Mobility is typically conceived of as a process that operates on the scale of kilometers. Mobility, however, occurs at many different scales, and within the context of residential sites, movement very often operates at the scale of meters. Furthermore, small scale decisions about mobility and spatial positioning within residential locations are one of the fundamental drivers of the kind of archaeological spatial patterning that is regularly observed in archaeological sites. After all, archaeological excavation most often occurs at the scale meters or tens of meters. For this reason, the Dukha Ethnoarchaeological Project was designed to develop theory of human spatial behavior at small scales by shifting the focus of spatial ethnoarchaeology from the mapping of features and material refuse to the direct mapping of people within the campsites of nomadic Dukha reindeer herders in northern Mongolia. Its most general aim is to explore how people
decide where to do what they do. In this paper, I examine some of the factors governing human mobility and spatial positioning in the interior and exterior spaces of Dukha summer campsites and their implications for archaeological spatial patterning.

[245] *The Implications of Biodistance Analyses of Initial Period (1550-1250 B.C.) Human Remains from Gramalote, Peru, for Our Understanding of the Social and Economic Dynamics of Ancient Andean Maritime Communities*

The importance and distinctiveness of Peruvian fisherfolk, or pescadores, and their complementary role in coastal valley economies feature prominently in a number of early ethnographic accounts (Ramirez 1995, Rostworowski 1976, 1977), and clearly, archaeological evidence indicates that large permanent fishing communities existed for centuries before. What is unclear is the degree to which, if any, these communities remained biologically distinct from other contemporaneous inland communities. Here we report preliminary biodistance analyses for 42 individuals from the north coast early Initial Period (1550–1250 B.C.) fishing community of Gramalote and discuss their relative distinctiveness from other roughly contemporaneous and subsequent human skeletal populations from the same region.

**Sutton, Wendy**

Since the earliest research at Chimney Rock, in the 1920s, where and how the villagers of Chimney Rock’s Pueblo II High Mesa settlement group got their water has been a puzzle. The High Mesa area is located 1000 feet above the valley floor. Recent research has expanded our understanding of water control at Chimney Rock; we are beginning to recognize a complex water management strategy that included check dams and features related to both tinajas and reservoirs. These features can help us understand the complex relationship the Ancestral Puebloans had with this mountainous environment. The water management system also provides clues on how Ancestral Puebloans may have extended the agricultural season and on later migrations.

[35] *The Kadambas and Banavasi: Perspectives from Archaeology and Epigraphy*

In this paper, I discuss the results of a multi-scalar investigation of regional complexity at Banavasi, an Early Historic settlement which rose to prominence as the capital of the Kadamba polity (4th-6th centuries A.D.). Specifically, I focus on the period between the early centuries A.D. and the 7th century, and show how results from a systematic archaeological survey as well as data from inscriptions allowed me to access multiple spatial and temporal scales of analysis. First, my investigation of the archaeological landscape at the site allowed me to trace its development as a Early Historic center, linked to its location in an early trade and (Buddhist) pilgrimage network. Second, my analysis of an ‘assemblage’ of elite inscriptions enabled a regional scale of analysis placing Banavasi within the context of shifting core areas of elite authority in the Karnataka region and allowing me to discuss the nature of political authority. Ultimately, my aims in this paper are two-fold: first, to discuss the early development and organization of the complex polity centered at Banavasi during the early centuries A.D. and second, to illustrate a larger
methodological point about the complementary use of archaeological and historical/epigraphic data.

Preliminary Results from the Genomic Analysis of Southwestern US Maize Landraces

Modern domesticated crop plants provide a unique resource for understanding past plant-human interactions, cultural preferences, and a proxy for interaction between human groups. Maize is arguably the most important domesticated crop plant in the Americas, and intricately woven into the food systems and cosmologies of New World peoples. In collaboration with Native Seeds/SEARCH, we grew out 108 landrace accessions on the NSS conservation farm in Patagonia, Arizona from across north Mexico and the Southwestern United States. We characterized these accessions phenotypically, collected parental genotypes, and generated hybrid seed by crossing individuals to a common inbred tester. The hybrids will allow us to sample haplotypes from these populations for population genetic and quantitative genetic inference.

Camelid Husbandry Practices and Textile Exchange in Northern Peru

This paper presents carbon and nitrogen isotopic compositions from South American camelid tissues and textiles composed of camelid wool from several archaeological sites in northern Peru spanning the Early Intermediate to Late Intermediate Periods (200 BC to AD 1476). Marked differences in isotopic compositions are present between camelids recovered from low altitude and coastal sites in comparison to high altitude sites, suggesting markedly different animal husbandry practices in these regions. Textiles recovered from coastal contexts present isotopic compositions that are consistent with distinct production strategies for materials according to spinning and weaving tradition. These results are discussed within the context of understanding variation in animal husbandry practices and the trade in camelid products in the region.

Tactical Power, Interaction, and Landscape Control during the Late Intermediate Period (1100–1470 C.E.) in the Huanangue Valley, Peru

This paper examines the outcomes of interaction between Chancay settlers and local chaupiyunginos in the Huanangue Valley, Peru, during the Late Intermediate Period (1100-1470 C.E.). Drawing from Foucault and Eric Wolf, I will examine how social power was tied to interactions between people as well as between people and the landscape. Using data from the Huanangue Valley Survey, as well as from excavations at the chaupiyungino site of Campo Libre and the Chancay settlement of Salitre, this paper will argue that the local chaupiyunginos were able to leverage their superior knowledge of the landscape as well as their control of the irrigation intakes into organization/tactical power (sensu Wolf 1999). This, in turn, allowed them to improve their position vis-à-vis the wealthy Chancay settlers who had recently
established a foothold in the valley. This resulted in a situation in which there was little power asymmetry between groups in the valley, which in turn may have led to favorable conditions for the formation of an alliance between Chancay settlers and local chaupiyunginos.

[40] Detection of Human Landscape Modification Associated with Food Production Using Paleoecological Proxy Evidence

Regionally nuanced social interactions between agriculturalists, pastoralists and foragers have affected economic phenotypes through history in East Africa. Thus, documenting the pre-colonial production emphases of East African populations comprehensively is crucial to understanding the adaptive significance of variation in economic activities in this region. The integration of fungal proxy data with pollen and phytolith data as part of a comprehensive paleoecological analytical strategy is an approach that is just beginning to gain momentum. If paleoecological proxy evidence can be confidently aligned with known archaeological phenomena, significant insight into the ecological and cultural context of emergent agro-pastoral economies may be gained. Analyses of pollen, phytoliths, and fungi derived from sediment cores can produce valuable data, usable by archaeologists, concerning the geographic, temporal, and cultural scope of agro-pastoral economies in this region. Pilot data from Yala Swamp (Nyanza, Kenya) are discussed which confirm this potential and suggest the need for further exploration of the utility of multi-proxy paleoecological data sets in landscape scale environmental and economic reconstructions. The potential for these proxies to produce conflicting sets of information may allow researchers to gain more detailed knowledge of the probable human and environmental activities producing paleoecological assemblages.

[73] Deployment of Cultural Meanings in the Central Kalahari

Two groups of San, the G|ui and G||ana, have lived in the central part of the Kalahari Desert, although Botswana’s development program has encouraged them to live in permanent settlements and has had a major impact on their lifestyle. Their spatial cognition is complemented by a multi-scaled integration of folk knowledge that enables them to acquire ample bush food by moving frequently and flexibly within their immense living area, now encompassed by the Central Kalahari Game Reserve. When they move through the bushveld, they sometimes mark the environment. For instance, a hunter tracking an animal may leave twigs on the ground to communicate the direction of his movement to his followers. However, these modifications to surroundings are limited primarily to simple, practical signs and rarely reach the systematic articulation of sacred significance. This is because they are oriented to attuning their acute senses to the complicated spatiotemporal structure of their surroundings rather than to trying to control nature through grasping its entirety. For the G|ui and G||ana, n!oo (translated as “land”) refers to a particular place in which a variety of cultural meanings operate. The cultural meanings are continuously constructed via unfolding social interactions embedded in the natural environment.

[66] The Postclassic of Southwestern New Mexico: Regional Variation in the Mimbres Area ca. A.D. 1150-1500

During the late 1970’s, Mimbres Foundation archaeologists noted the presence of distinctive architectural styles and artifact assemblages on sites along the Mimbres River apparently post-dating the region’s infamously heavily looted Classic period pueblos, proposing two new Postclassic phases: the Animas/Black Mountain phase (ca. A.D. 1130/50-1300) and the Cliff/Salado phase (ca. A.D. 1300-1450/1500). In this paper, we discuss how Mimbres Foundation work shaped decades of subsequent
Postclassic research in the greater Mimbres region (Mimbres Valley, Eastern Mimbres, and Upper Gila). That research suggests that, just as the Classic Mimbres was far more dynamic and variable than originally proposed, so too were developments in the Postclassic. With this dynamism and variability in mind, we provide a synopsis of recent research in the greater Mimbres region, highlighting variability in settlement patterns and social interaction. We discuss new survey and excavation data that are refining Postclassic chronology, and examine ceramic and obsidian sourcing studies to gain a more detailed understanding of the reorganization of Postclassic social connections. We call for a critical reevaluation of the Postclassic phase system that incorporates this variability.

[201] Bioclimatic Modeling Approach and Long-Term Human Population Dynamics in Glacial Europe

Bioclimatic envelope or niche models have become standard tools in predicting future changes in the occurrence and abundance of plant and animal species, and a similar approach is increasingly used also to study past climate-related changes in species distribution. Given the fact that climate has an effect on human hunter-gatherer population densities, we argue that a bioclimatic modeling approach can be used to study human populations, as well. We show that by using an ethnographic dataset of terrestrial hunter-gatherers, model-based climate data, and bioclimatic modeling tools it is possible to simulate range and size dynamics of the human population in Glacial Europe between 30,000 and 13,000 years ago. Because this simulation is not archaeologically informed, it can be evaluated against the archaeological record. The simulated population size and range agree well with patterns in the archaeological population proxy based on $^{14}$C-dates. This correspondence indicates that the elementary climatic factors used in our simulation had a strong impact on long-term hunter-gatherer population dynamics. The consistency between our simulated patterns and the archaeological data is remarkable also because it suggests that the climatic envelope of terrestrial hunter-gatherers has remained more or less unaltered from the late Pleistocene to present.

[226] Progress in Land Transportation System as a Factor of the State Formation in Japan

Horses were introduced to the Japanese islands from the end of the fourth to the middle fifth centuries. The introduction was crucial in the development of land transportation system and eventually the state formation. Prior to the introduction of horses, water transportation was important. This was particularly the case because iron had to be imported from the Korean peninsula. In this sense, western Japan was advantageous in the acquisition of iron because western Japan was closer to the Korean peninsula and the Inland Sea that provided an important sea route was located in western Japan. On the contrary, eastern Japan was characterized by mountainous environment. A situation changed considerably when horses were adopted for transportation of goods by the central polity in the fifth century. Owing to this, iron became widely available in eastern Japan. Horse riding also made it easy to interact with distant or mountainous communities. This resulted in the development of spatial, rather than linear, network of communities, which made it easy for the central polity to gain control over more local communities than ever in the fifth century.

[158] Catastrophic Volcanism, Climate Change, and Ancient Urbanism in the Maya Lowlands

Maya urban centers in the southern Yucatan Peninsula were typically low-density “garden cities” largely dependent on their immediate environs for agricultural production. Catastrophic volcanism was a critical factor in the development and maintenance of Maya urban centers because it helped sustain the region’s agricultural system by helping renew regional soils. Flourishing of ancient Maya cities in a difficult environment depended on a flux of volcanic material occurring within an optimal window. Wind patterns and rainfall are seasonal, linked to the shift in the Intertropical Convergence Zone (ITCZ). During the wet season, the ITCZ sits over the Yucatan Peninsula with Trade Winds and Easterly Waves predominating and blocking ash fall from reaching the Maya Lowlands. During the dry season, the southward shift of the ITCZ allows westerly and southerly winds to bring erupted ash over the region. Ash fall occurring during
the dry season posed a risk for ancient Maya that were dependent on capturing and storing rainwater to meet their water needs because of the problem of reservoir fouling. The Maya Lowlands experienced intermittent periods of increased aridity, which amplified drought frequency and severity, and likely contributed to periods of disruption in the course of Maya prehistory.

[146] Paracas at Chincha Valley: A View from Cerro del Gentil-El Mono Complex
In this paper we present recent data in our research in the middle valley of Chincha, which focused on settlements with occupations usually recognized as Paracas Andean archaeology. The theoretical basis of this work focuses on understanding of the processes of state formation in the Early Intermediate Period in this region. In particular, we focus on the emergence of complex Paracas settlement in the middle valley. One of these, in particular, a pyramidal site known as Cerro del Gentil, was excavated and mapped. The data suggest that the pyramid was built in the time of Paracas and continued, subsequently, with a Carmen occupation. We also found numerous geoglyphs in the Pampa de El Carmen which align with several Paracas / Carmen sites in this part of the valley. Additionally, we present the preliminary results of the intensive survey in the middle valley of Chincha which also focuses on Paracas sites. Thus, in this paper we present a summary of the data retrieved in the research seasons 2012 and 2013, with which we hope to offer an idea of the nature of the occupation of Paracas in the middle valley of Chincha with implications for all the valley.

[62] U-shaped Platforms along the Gulf Coast and beyond
Two apparently similar architectural features, a U-shaped platform and a U-shaped bench, appear at several sites along the Gulf Coast. First appearing at Formative sites, the U-shaped platform is also found at Classic Period Gulf Coast sites and at Teotihuacan as well. This paper explores the sculptures and features associated with these platforms and considers their significance in each context.

[233] Lost Graves at Hanna’s Town Cemetery, Westmoreland County, Pennsylvania
Hanna’s Town (36WM203), an 18th-century site located in Westmoreland County Pennsylvania, was a major settlement on the western frontier that was attacked and destroyed by a joint force of British and Native Americans in 1782. The town never fully recovered, and by the early 1800s, no buildings remained from the settlement, and the land was repurposed for agricultural use. Today, Hanna’s Town has been reconstructed for tourism purposes. The site contains a cemetery that currently has six grave stones. The Westmoreland County Historical Society has several gravestones in their possession that are no longer associated with burials. These headstones provide evidence that the cemetery contains lost graves, but it is believed that they do not account for all the burials at the site. Geophysical investigations using ground penetrating radar (GPR), magnetometry, and down-hole magnetic susceptibility readings were undertaken during the winter of 2014 to examine the possibility of other grave shafts at the site. This poster summarizes the results of these investigations.

Taylor, William (University of New Mexico)
[301] Equid Cranial Remains and the Antiquity of Horseback Riding in the Mongolian Steppe
The adoption of horseback riding in the Eurasian Steppe is central to many models of political and social
development, but questions remain over the timing and sequence of equestrian practice in Mongolia. Equine crania and postcranial remains buried around “deer stones” and other monumental features from the Mongolian Bronze Age represent a primary, yet understudied dataset for establishing the antiquity of horsemanship in eastern Eurasia. On the basis of age, pathologies, and previously undocumented osteological features from cranial and mandibular remains from 29 Bronze Age horses in Mongolia, this poster argues that horsemanship was likely well established in the “Deer Stone-Khiringgusur” culture. Other archaeological and experimental evidence suggests the use of an organic bridle during this period, which might have failed to leave typical forms of “bit wear” and hampered the recognition of horseback riding in archaeological contexts. 3D scanning technology presents a novel and potentially valuable means of quantifying and comparing cranial information from Bronze Age Mongolian horses. Future research will focus on expanding the sample of Bronze Age skeletal material through excavation, as well as exploring skeletal traits of modern feral horses to establish an archaeological methodology for new lines of cranial evidence.

[155] Above Ground – Below Ground: Assumptions of Status and Mortuary Expenditure
Cemeteries and burial markers are prominent, visible reminders of the lives that have passed before us. With painstaking effort, these landscapes and artifacts are being maintained and conserved by descendant populations, community organizations, churches, scholars, and other interested parties. Mortuary studies typically assume that large monuments have a positive correlation to the status of the deceased and to the below ground expenditure. This study will test that assumption through the use of funeral records and mortuary marker analyses. George W. Loudermilk and People’s Undertaking Funeral Records dating between 1902 and 1927 will be compared to markers at Greenwood (White population) and Woodland (Black population) Cemeteries in Dallas, Texas. These funeral records provide a unique glimpse into actual funerary expenditures and detail individual information such as names, dates of death, cemetery, and occupation of the deceased. Using the funeral record data, a subsample of markers from known individuals were analyzed from Greenwood and Woodland Cemeteries. This will test the assumptions regarding status and socioeconomic cost in mortuary sciences.

[104] 3-D Modeling of Area 3 at Cerro Huancha, Sinsicap Valley, Peru
Cerro Huancha, the largest archaeological site in the Sinsicap Valley a tributary of the Moche River in northern Peru sits in the desirable Chaupiyunga ecological zone between the lowland north coast of Peru and the Andes Mountains. Archaeological investigations at Cerro Huancha, from 2010 to 2012, inform the sociopolitical function of Cerro Huancha and its yunga residents’ interaction with Late Andean polities. This poster presents a spatial analysis of architecture from Area 3 during its final occupation. Area 3 is a series of compounds constructed on terraces on the southwest side of the site. 3-D reconstructions supplemented with information from excavations reveals access patterns between architectural compounds in Area 3 and it’s relationship to other areas on Cerro Huancha.

[142] The Current Pimu Catalina Island Archaeology Project
The Southern Channel Islands off the coast of California were home to the ancestors of the Gabrieleno/Tongva for at least 10,000 years. The Pimu Catalina Island Archaeology Project was founded in 2007 as a collaborative undertaking between the Gabrieleno/Tongva community, archaeologists, and the Catalina Island Conservancy to synthesize and expand upon the previous research conducted on the island for over fifty years. Many difficulties, including the finding of original documentation, collections, and original site locations, have been daunting, but successful. The field seasons of 2012 and 2013 have propelled the project forward in amazing ways. This presentation will discuss current research, programs, and overarching goals that help us to better understand the Pimu people and their way of life.

[223] Adaptive Network Strategies and Landscape Use: Geochemical Obsidian Sourcing and Tool Consumption during the Last Glacial Maximum in Hokkaido, Japan

The Last Glacial Maximum (LGM), roughly 20,000-17,000 14C BP, was a watershed in Japanese and NE Asian prehistory as humans were forced to reorganize themselves to cope with extreme ecological deterioration during one of the coldest time periods in human history. In this paper we explore adaptations during this time to both social networks and landscape use in the Tokachi and Ishikari lowlands of Hokkaido at the Shimaki, Kawanishi C, Kashiwadai 1 LC 11 sites. Specifically, we first compile XRF geochemical obsidian sourcing data on all formal tools to model social network analysis of exchange- based relationships of this resource at the sites. Next, consumption rates of these tools are compared to construct behavioral scenarios of how the obsidian resources were managed after procurement or exchange as well as group mobility patterns in relation to subsistence resources.

[252] Geochemical Signatures of Contemporary and Ancient Maya Activities in Public Plazas

Public plazas are the centers of important social activities in both contemporary towns and cities and at ancient Maya sites. Public rituals and celebrations likely involved feasting that required both food preparation and waste disposal. Marketplace activities required organization for the assignment of vending space for sellers, pathways for buyers and the trade of similar classes of merchandise. Public architecture at plazas included walls, causeways, water sources, low platforms and sometimes post holes and rock alignments that demarcate vending space. But the artifacts of ancient activities were either swept away or decomposed. Hence, it is important to gather the chemical residue evidence of plaza activities before they are contaminated or destroyed by modern activities. An equidistance triangular grid sampling method is proposed to help improve the resolution of geochemical results and increase the probability of capturing linear patterns of activities. Analysis of the invisible chemical residues of those activities enriches our understanding of ancient lives. These techniques should be incorporated into research investigations of ancient sites to enhance our interpretations of human activities, including economic activities in public spaces. Geochemical signatures of contemporary and ancient plaza activities at Telchaquillo and Coba, Mexico and Caracol Belize will be reported.

[112] Nuevas identidades visuales en Cacaxtla-Xochitecatl, Cholula y Cantona: interacciones epiclásicas con Oriente mesoamericano

Las interacciones interregionales en sitios del área cultural de Puebla-Tlaxcala se han abordado desde el siglo pasado; en Cholula (con Veracruz), pero sobre todo a partir del descubrimiento de los murales de Cacaxtla en los años 1970 (con Veracruz y área maya). Sin embargo, a pesar de una rica historiografía sobre la iconografía de estas representaciones, ninguna síntesis ha puesto en relieve una visión regional, abarcando un panel más amplio de materiales e testigos arqueológicos. Esta ponencia presentará los resultados de las investigaciones llevadas a cabo durante mi tesis doctoral. Estas subrayan las diferentes modalidades de fenómenos de interacciones culturales entre Cholula, Cacaxtla-Xochitecatl, Cantona, la costa del Golfo por una parte y el área maya por otra. Diferentes tipos de materiales ilustran estas diversas modalidades: en un proporción muy baja, materiales importados, pero mucho más frecuentemente, adaptaciones e hibridaciones iconográficas que dan cuenta de varias estrategias socio políticas de legitimación. Estas, a su vez, pueden insertarse en la teoría de "connection-disconnection" propuesta por Stone (1989). En un periodo de competitividad regional, también pueden entenderse como una voluntad franca de distanciarse de la identidad visual de Teotihuacan.

[299] The Early Upper Paleolithic at Espadanal: Contextualizing Gravettian Technological Variability in Central Portugal
The stratified site of Espadanal aids resolution of two long-standing archaeological controversies in the Upper Paleolithic of Portuguese Estremadura. The earliest archaeological level at Espadanal exhibits the unusual combination of a large blade industry manufactured exclusively from chert with an EUP bladelet technology fashioned primarily on quartz. Integrated geoarchaeological analyses including fabric analysis facilitate a reconstruction of the site’s depositional history. Detailed understanding of the site formation and postdepositional processes that impacted the artifact assemblage supports the conclusion that these two very different technologies indeed co-occur during the early Gravettian period. Both absolute dating (OSL and radiocarbon) and the geology of the floodplain landforms suggest a terminus post quem of 30,000 years BP for the nearby, disputed EUP site of Gato Preto.

[284] Food and Fertility: An Evolutionary Context for Understanding Hunter-Gatherer Demographic Shifts

This paper presents the recent results of research designed to elucidate the dynamic interrelationships between foodways, the environment, and human population growth in prehistory. Specifically, this case study evaluates temporal variation in how hunter-gatherers reduced food risk during a period of significant population growth on the Northern Channel Islands of California. The outcome of this research includes the most comprehensive integrated foodways research that has ever been completed on the California Channel Islands. Combined with a well-supported, rigorous chronological framework and reconstruction of seasonal mobility patterns this research revealed substantial shifts in how prehistoric people moved about and exploited the landscape immediately prior to the period of significant population growth.

In southern Africa, archaeologists have often used ceramics as a marker of ethnic and linguistic identity. However, the detection and understanding of various pottery types in the archaeological record is a problem that needs to be engaged further using ethnoarchaeology. Hodder’s 1982 research suggested that not all material culture style boundaries reflect cultural/linguistic boundaries. They can also reflect other boundaries such as ethnic, social, linguistic, age, class, political and administrative among others. The purpose of this project is to elucidate the relationship between ceramic style, social groups, technology, learning patterns and how that can apply to archaeological situations. Some of the questions in this paper are: What aspects of social, stylistic and technological boundaries do ceramic styles reflect in southern Africa today? The purpose of this study is to clarify the current relationship between ceramic styles, technology and social boundaries in south-eastern Botswana. This aim is realized through an ethnoarchaeological study of ceramics produced by twenty modern potters from five different ethnic groups and/or merafhe (Bakwena, Bangwaketse, Bakgalagadi, Bakgatla and Nalete) in south-eastern Botswana and to map boundaries in: clay collection techniques, procedures, and processing/paste preparation; vessel forming, decoration and finishing, firing and post firing treatment and learning patterns.

[96] Facilitating Outreach and Education on a Grassroots Level

The nature of heritage education has changed tremendously in the 26 years since “Save the Past for the Future.” While the idea of professionalizing heritage education is desirable, there are fewer opportunities for interested professionals and funding and resources are not easily available. At the Archaeological Institute of America (AIA) public outreach is part of our mission yet, with minimal human and financial resources we have had to be creative and flexible in order to design programs that have a significant and widespread impact. In 2004 the AIA established an Outreach and Education Program and since then has
been expanding its outreach efforts throughout the US, Canada, and around the world. These efforts are being done on a local level through our Local Societies, which are being supported by small Society Outreach Grants on a global level through International Archaeology Day, and by forming collaborations with like-minded organizations to present joint programs. In this paper we will discuss these initiatives and present our latest endeavor—participation in regional and national Science Festivals. Through this discussion we hope to highlight the effectiveness of facilitating grassroots efforts to reach the largest possible audience through a diverse array of activities.

La Ruta del Spondylus: The Role of Spondylus Shell in the Rise of Socio-Political Complexity in the Andes

Archaeological interpretations on the rise in social, political, and economic complexity along the Andean spine posit an intricate history in which the environment, kinship ties, and socio-economic trade play significant roles. To evaluate this, researchers use a temporal and regional scale on one type of artifact or ecofact to trace its function and role, as well as the morphological shifts it experiences. One resource functioning as an artifact and ecofact, which can truly aid in archaeological interpretation of social stratification and structure is the thorny oyster, or Spondylus calcifer and Spondylus princeps shell, found in the Pacific Coast of South America, particularly along Ecuador’s coastline. This research, under a practice theory framework, aims to employ Kopytoff’s (1986) ‘commodity chain analysis’ model to the diachronic investigation of the role of spondylus shell as categorized within each of Binford’s (1962) artifact classes. These classes will demonstrate the correlation between the rise in spondylus as a symbol of community ideology with the rise in complex socio-political organization throughout the Andes. To accomplish this, assemblages along the ruta del Spondylus from the Early Horizon time period onward will be analyzed, with particular interest in coastal, inland, and mainland sites within Ecuador and Peru.

“I am a Lion/I am Virile”: The Royal Hunt in Neo-Assyrian Images and Texts

Ancient Mesopotamia, where complex dynastic culture developed at a very early date, is also one of the first spaces in the world where evidence of a proper “royal hunt” appears. From development of the Uruk culture in the 4th millennium to the Persian conquest in 539 BCE, the trope of the royal hunt of wild animals persisted in ancient Mesopotamian images and texts. This trope is most abundant during the Neo-Assyrian empire, based in northern Mesopotamia during ninth through seventh centuries BCE. The kings of Assyria frequently represented themselves as the masters of lions, wild bulls, elephants, deer, and other local and exotic fauna. The settings of these exploits could be in the open wild beyond the borders of their heartland or within bounded “game parks” adjacent to their capital cities. They displayed this taming of chaotic nature in images of the hunt on portable luxury objects and stone reliefs that adorned their palace walls as well as narrative texts that proclaimed their royal deeds. The excavated evidence from the Neo-Assyrian palaces allows us to explore how kings from the period constructed identities of physical power and virility by simultaneously associating themselves and dispensing with formidable animal foes at home and in the distant hinterland.

The Fluid Histories of Island and Coastal Polities

In this paper we provide an overview of the various ways social and political histories unfolded among
island and coastal societies. Our goal in presenting this overview is to explore some of the alternative paths that complex political relationships played out among such groups. We recognize that access to economic resources and other such characteristics (e.g., island size, proximity to mainlands, raw materials, biotic resources) play an important role in such histories. However, in our synthesis, we seek to illustrate how political and social actions and the materiality of quotidian activities articulate with larger economic structures that are often the focus of archaeological studies of complexity. To accomplish this goal, we draw on the studies presented in this symposium, case studies from our own research, and other global examples to explore both the regularities and unique histories of how complexity has developed among island and coastal groups.

Local Variation of Settlement Patterns at Uxbenká and Ix Kuku’il, Toledo District, Belize

Uxbenká and Ix Kuku’il are neighboring Maya centers located in the southern foothills of the Maya Mountains, Toledo District, Belize. LiDAR data gathered in 2011 aided in the identification of the small center, Ix Kuku’il. In 2013, a 10-day survey of the area surrounding Ix Kuku’il identified 42 residential groups and eight civic/administrative groups spread across an area of 9 km². This poster will compare the pattern of settlements at Ix Kuku’il to that documented at Uxbenká, a Classic Maya center located 6.4 km to the southeast. GIS analyses were used to examine variations in the settlement patterns and residential group arrangements between the two sites. Analyses of surface artifact assemblages from households at Ix Kuku’il and artifacts excavated from residential groups at Uxbenká speak to potential economic ties within and between these peripheral Maya centers and the greater Maya region.

Thompson, M (Arizona State University)

Social Memories of the Dead in Prehistoric Hohokam and Zuni Communities

This paper addresses the social memories and identities surrounding spirits of the dead in late prehistoric Hohokam and Zuni communities. I compare the performance of mortuary ritual in several Classic period Hohokam settlements of the lower Salt River valley with the performance of mortuary programs at Protohistoric era Zuni villages. The comparative mortuary analysis evaluates large, integrated mortuary data sets from three settlements on the north side of the Salt River and from the Zuni towns of Hawikku and Kechiba:wa. Here, I discuss a multivariate statistical approach that focuses on body treatment and spatial distribution in these villages; this approach also assesses construction of mortuary facilities and decommissioning of particular material objects. Interpretation of patterns references ethnohistoric and ethnographic records on relationships with spirits of the dead in the American Southwest. Analysis results highlight the identities that the living created for the spirits of the dead and emphasize the relationships that people maintained with these beings. The study encourages us to recognize that Prehispanic communities of the Southwest were composed of both the living and the spirits of the dead.

Sacrificial Tribute Reconsidered: New Dental and Isotope Evidence of Biological Distance and Place of Origin for Sacrificial Burial Groups at Cahokia’s Mound 72

Many theories related to the significance of Mound 72 at Cahokia center on the importance of human sacrificial tribute as evidence of Cahokia’s power and influence over surrounding communities. Two of the larger burial groups thought to represent sacrificial offerings are F105, a mass burial containing over fifty mostly female individuals, and F229-lower, a group of haphazardly deposited individuals with evidence of violent trauma that were interred beneath a row of presumably high-status burials placed on cedar litters (F229-upper). The unique burial context of F229-lower led to speculation that these individuals were non-local, warfare related captives. However, biodistance analyses conducted in the early 1970s provided unexpected results: while individuals in F105 stood out as being non-local, F229-lower burials did not. In this study, we reevaluate these findings using strontium isotope (87Sr/86Sr) and phenotypic dental data. Results of the dental biodistance studies contradict the earlier findings and suggest that F105 individuals were local to the American Bottom while F229-lower individuals are biological outliers. Preliminary strontium isotope data corroborate these findings. This new information provides an alternative perspective on the mortuary events that unfolded at early Cahokia.

[113] Ancient Maya Turkey Husbandry and Exchange: A Multi-Proxy Approach

Large gaps exist in our knowledge of ancient Maya turkey husbandry and use. Among the questions that still need to be addressed are: 1) when and where was the non-local domestic turkey (Meleagris gallopavo) introduced to and adopted by the ancient Maya?; and 2) did the ancient Maya also rear captive or tame populations of the local ocellated turkey (Meleagris ocellata)? This paper presents preliminary results of an inter-disciplinary research project aimed at answering such questions. The research combines isotopic, morphological, osteometric and genetic analyses to reconstruct the history of turkey husbandry and exchange in the Maya Lowlands. Emphasis in this presentation will be on isotopic results from a subset of turkeys from the Postclassic site of Mayapan, where husbandry of ocellated turkeys has been suggested, but not tested. The results of this analysis will be contextualized within the framework of the larger project.

[340] Extra-moundbuilding Activities in the Floodplain: A Zooarchaeological Perspective from the Mound House Site (11GE7)

Within the built landscape of the lower Illinois River valley, floodplain mound groups served as prominent spaces of multi-community interaction. Notable among these is the Mound House site (11GE7), which is best representative of the Middle Woodland (ca. 50 cal BC–cal AD 400) period. While monumental earthworks of the region have elicited considerable attention from scholars, little is known about these sites outside of their associated moundbuilding and mortuary programs. Associated habitation areas have rarely been the focus of archaeological investigation. In order to enhance our resolution of land use and subsistence strategies at these often overlooked components of floodplain sites, this study examines a portion of the faunal assemblage from an impressive Middle Woodland pit feature, presumably created though intensive seasonal use of the site. Results of this analysis are used to discuss the possible activities occurring at the site during the Middle Woodland period apart from moundbuilding.

[110] Vernacular Architecture in the Chacoan World

Chaco Canyon, in the North American Southwest, was the center of the Ancient Pueblo world between A.D. 850 and 1150. Monumental architecture—great houses, great kivas, road segments, and earthworks—characterizes 12 major sites in Chaco Canyon and is found at approximately 100 outlying communities in the surrounding region. Monumental Chacoan buildings are massive, formal, symmetrical, and made of core-and-veneer masonry. The monumental structures are associated with communities of 20-40 small habitation sites characterized by informal, asymmetrical floorplans and a variety of construction materials. The vernacular architecture of small sites has garnered less archaeological attention than monumental Chacoan buildings, both within Chaco Canyon and in outlier communities. Chaco outlier communities have been identified through monumental architecture, and contemporaneous communities lacking this architecture have been overlooked. Furthermore, the similarities and differences in vernacular architecture between communities have not been explored. By adopting a comparative approach to small-site vernacular architecture, we hope to better understand interactions among Chacoan and extra-Chacoan communities.

[188] What lies Just Below the Surface: Multi-Instrument Geophysical Study at Mawchu Llacta, Peru

This paper details the results and interpretations of multiple geophysical survey blocks within a planned colonial town in highland southern Peru for the Proyecto Arqueológico Tuti Antiguo. The relict reducción, known today as Mawchu Llacta (Quechua for “old town”), is remarkable for its excellent architectural preservation and minimal looting disturbance. The site is known through abundant oral historical
testimony that suggests a relatively recent abandonment of the reducción in the mid-19th century. These attributes, together with the extensive documentary record, make it an ideal locale for investigating a number of issues related to resettlement and the emplacement of reducciones in the landscape, including construction, domestic life, and religious practices. Both geo-magnetic survey (flux-gate gradiometer) and ground-penetrating radar were utilized to assess the potential for buried cultural features and anthropogenic deposits. The wealth of information gained on site matrix characteristics from each instrument reinforces a multi-instrument approach. Survey areas were located in five distinct locales of the settlement each providing a unique context within the site. The surveys met with great success and difficulty equally, and both factors will be discussed in this paper.

[138] Assessing the Exchange of Granite Ground Stone Tools at San Estevan, Belize, through Portable X-Ray Fluorescence

The Maya site of San Estevan has a varied assemblage of ground stone tools, dating to the Late Classic Period. These tools are constructed from igneous, metamorphic, and sedimentary materials. This study focuses only on the granite artifacts in order to assess the ability of portable x-ray fluorescence (PXRF) on a heterogeneous material. PXRF has previously been used for chemical characterization of homogeneous materials such as chert, obsidian, or ceramic. These studies have shown that PXRF is able to identify source locations for these materials. Fieldwork was conducted by the author in the summer of 2013 to collect outcrop samples of granite from the three distinct batholiths present in the Maya Mountains of Belize: Cockscomb Basin, Hummingbird, and Mountain Pine Ridge. Geochemical fingerprints were developed of each intrusive event. PXRF readings of the granite tools recovered from San Estevan generally group within known outcrops, indicating a specific region of origin within Belize. Locating a source region allows for the interpretation of potential exchange relationships between central Belize communities and northern communities such as San Estevan. In addition to locating potential resource areas, this study provides a new, nondestructive method for sourcing granite artifacts.

[25] Cultural Head Forms and Shifting Group Identity among the Western Maya during the Classic Period

The modification of the infant’s head through constriction and compression devices constitutes a form of physical embodiment that has been employed cross-culturally to signal ethnicity, social integration, and gender. This paper explores the emblematic roles of head shaping in publicly displaying individual and group identity (potentially ethnicity) across and beyond the Western Maya hemisphere. Here, Classic period cranial vault modification, as conferred by female folks to their offspring, was not only widespread but also noticeably diversified in its visible results. Conceptually anchored in the multi-layered native meanings of this deeply rooted body practice, this paper confronts the area’s cranial record and head portraiture with the mosaic of vernacular languages in an increasingly divided political landscape. While narrow, inclined, and elongated heads were prominently displayed among the Western Cholan folk of the Usumacinta basin, bordering Tzeltalan and Zoque communities on and beyond the Maya western fringes sported visible broad and shortened heads, some of them bilobular. We discuss the shifting landscapes of head display in terms of identity vs. alienation, interaction vs. antagonism, within and among communities and urban neighborhoods, posing that head shapes were to attain new meanings for their human carriers, especially in the aftermath of political collapse.

Cave Art Soundscapes: Experimental Music Archaeology in the Painted Caves of Northern Spain

Various sound-making tools, including bullroarers and bone flutes, have been found in caves that feature Upper Paleolithic decoration, such as painting and carvings. Such sounds, combined with the unusual acoustics of these spaces, their extreme quietness, and the restricted visual cues provided by small flickering light sources, must have made sound particularly important to those who visited them in the past. A recent multidisciplinary project in northern Spain explored the sonic culture of five caves that are part of the Cave of Altamira and Paleolithic Cave Art of Northern Spain world heritage site. Various appropriate sound making tools (such as voices, cow horns, bone flutes and percussion) were used to stimulate the acoustic response of the caves, to illustrate and assess what it may have sounded like to be there in the ancient past. A short film has been made to experimentally explore the spaces using audio-visual digital studio techniques including convolution and photogrammetric modelling, to attempt to better understand the archaeological context of the spaces experientially. The presentation will be illustrated with a number of audio and video examples. It will aim to better understand the role of sound in prehistory.

European Neolithic Population Surface

Recent work by the EUROEVOL team has included the use of summed probability distributions of radiocarbon 14 samples to infer demographic fluctuations, revealing unexpected boom-bust patterns in the European Neolithic. In this presentation we offer an extension of this work, presenting a dynamic population surface for the entire study area. This reveals demographic and migratory patterns at a fine spatial and temporal resolution, and we use statistical techniques to establish which fluctuations are significant. We further apply this method to other types of data in our unprecedentedly large database to build a picture of spatiotemporal fluctuations in agricultural practices, including animal husbandry and crop use.

Archaeology in a Smoldering Landscape: High Elevation, Post-Fire Research in the Greater Yellowstone Ecosystem, Wyoming

As the frequency and intensity of wildland fires have increased in mountainous regions of the western United States, both the research potential and threats to archaeological sites have also seen a dramatic increase. For over a decade, research on sites ranging in elevation from 2500-3300m within a study area of over 211,000 ha along the eastern margins of the Absaroka Mountains in northwestern Wyoming’s Greater Yellowstone Ecosystem has incorporated post-fire archaeological investigations into the study of regional Holocene land-use patterns. Much of this research has taken place within the Washakie Wilderness and has been conducted in collaboration with the USDA Shoshone National Forest. Multi-scale methods to document surface archaeological data from individual fires into broader, landscape patterns and to monitor fire impacts and changing site surface characteristics have been explored. Post-fire studies provide unique opportunities for surface survey to yield a picture of unprecedented resolution and complexity, but also pose vexing challenges at the interface between aspects of basic research, site stewardship, and applied/management process.
Toft, Peter Andreas (National Museum of Denmark)  
In the wake of increased European whaling in the late 17th century AD and the permanent presence of colonists and missionaries in the 18th and 19th centuries the historic Greenlandic Inuit were not only facing foreign people but also a new material culture in the form of European commodities. Trade was the main motivation for these cultural encounters Europeans, but the nature and duration of local encounters affected Inuit use and reception of foreign things. This cultural exchange cannot be reduced to the simple dichotomy of Inuit and Europeans as many groups were involved on both sides and the foreign commodities were accompanied by Europeans in some areas, whereas some Inuit groups acted as middle men in others. In this paper the strengths and limitations of using the interaction zone model are explored on a comparative regional and individual level focussing on the variable Inuit use and reception of European commodities in three Greenlandic regions: Disko Bay, the Nuuk Fjord and South East Greenland.

[154] Epigraphy in 3D: Digital Photogrammetry and Publication of Classic Maya Inscriptions  
The on-going decipherment and study of Classic Maya writing and iconography relies on timely publication of accurate line drawings and photographs of monuments and artifacts. Far from mere mechanical reproductions, such photographs and drawings reflect one's expert judgment and aesthetic preferences. Given that most monuments have suffered from intentional damage or erosion, line drawings constitute a key step between the epigrapher's initial interpretation of an inscription and/or imagery and its wider dissemination among scholars and wider academic and non-academic audiences. Digital photogrammetry offers a new level of precision and verifiability in the production of epigraphic illustrations, as it enables sharing of primary 3D data alongside its interpretation as renderings and drawings, potentially signaling a new era in the study of Classic Maya heritage. This presentation explores the emerging practice of digital epigraphy and its contribution to advancing our understanding of ancient monuments through a series of examples and case studies.

Tomaskova, Silvia (UNC Chapel Hill)  
[240] Clean Feminist Theory Meets Messy Practice  
When a dedicated feminist archaeologist encounters contradicting realities in the context of fieldwork or in the classroom that challenge core beliefs, she has several possible options. She can reflect on some of the basic tenets of her beliefs, or reexamine cultural contexts of the situation and ponder how easily feminism travels, or decide that we may have reached the ends of utility of "traditional feminism" and the time has come to move on. This paper will consider all these options in the context of fieldwork in Eastern Europe and South Africa, as well as the classroom in the 21st century North America. Translation, dissonance, and travel between different worlds will be key terms, suggesting that these may be simultaneously useful metaphors both for our practice in the present and for interpretation of prehistoric worlds.

Tomasso, Antonin (University of Nice - University of Pise) and Guillaume Porraz (CNRS / UMR 7041 ArScAn / AnTET)  
Since the early 80s and the development of techno-economical studies, the analysis of lithic raw material sources have became central to infer on the territorial range and/or the mobility strategies of Pleistocene societies. Results have been positive but somehow repetitive. For this session, we discuss the "embedded procurement" perspective, which presumes that raw material acquisition was part of other subsistence activities rather than an autonomous technological task. We suggest here that this perspective is a theoretical assumption which requires to be demonstrated case by case. We argue that this assumption has contributed to undervalue the rock selection within the process of tool production and underestimate the role of indirect procurements. Once emphasized how critical the initial step of a chaîne opératoire is, the raw materials does not appear anymore to be a by-product of mobility but more
likely a structuring parameter for hunter-gatherer societies. As an illustration, we selected examples from (Proto-) Aurignacian to Epigravettian sites located on the Mediterranean corridor (Provence-Liguria) and underline their main characteristics in terms of raw material provisioning strategies. However, first, we insist on the reliability of petrographic studies and on the relevancy of these areas to discuss the patterns of raw materials transport and selection.

Tomka, Steve (Center for Archaeological Research-UTSA) [119] Identifying Change among Texas Mission Indians as Reflected in the Written and Material Record

In the 1690s, the Spanish missionary wave began spilling across the Rio Grande and produced the first mission in south Texas, Mission San Antonio de Valero in 1718. By 1730, five missions dotted the upper reaches of the San Antonio River and were “home” to over 1,000 natives from South Texas. Nearly one hundred years later, in 1824, when the missions were fully secularized, only a few dozen neophytes were still living in the missions. Following secularization, native identity became virtually invisible in the archaeological record of nineteenth century San Antonio. This presentation focuses on the broader sociocultural processes that set identity change in motion even before the appearance of the first missions, the practices that have reinforced it in the missions, and the social conditions that cemented it after secularization. The archaeological and the ethnohistoric records are used to illustrate identity changes and their reflection in the material record.

Tomka, Marybeth (UTSA-CAR) [237] 25+ Years Later: The Significance of the Great Kiva at the WS Ranch Site, Alma, New Mexico—A Reevaluation

This paper will explore research completed under the direction of Dr. James A. Neely, Professor Emeritus, Department of Anthropology, the University of Texas at Austin. In 1988, my Master's thesis presented a theoretical viewpoint of the significance of the Great Kiva and the surrounding room block at the WS Ranch site (Tomka 1988). It summarized four field seasons worth of excavations (1977-1978 and 1984-1985), artifact analysis, and attempted to put the presence of a great kiva into theoretical context. In the 25 years since this work was completed, scholars have added to the literature in excavation results and social complexity-integration theory. I propose to reevaluate my original conclusions in the context of current models.

Toney, Elizabeth (Gila National Forest, Silver City Ranger District), Robert Stokes and Aaron Woods (University of Nevada Las Vegas) [66] Social Contexts and Community Organizational Roles of Classic Period Small Sites

The Mimbres Foundation’s 1970s-era processualist approach to salvaging data from looted Classic period sites in the Mimbres Valley was a milestone in Southwestern archaeology. Their work demonstrated that significant archaeological data remained and that there was still much to learn about the people of the Mimbres region. Prior research focused almost exclusively on the large pueblos, but to address gaps in knowledge related to other site types, the Mimbres Foundation undertook systematic survey of the valley and its major tributaries, documenting a range of sites from the Early Pithouse to Salado periods. Although focusing much of their excavation activities at two large sites, Mattocks and Galaz, several smaller Mimbres pueblos were also investigated. Recently, a renewed effort towards understanding the social and economic roles of smaller Mimbres pueblos in relation to larger Mimbres community systems has produced significant results. This paper reviews the pioneering work of the Mimbres Foundation’s studies of small pueblo sites and then presents recent survey, excavation, and GIS data that provide a new understanding of the multi-functional sociocultural roles of this often overlooked site type.

Toohey, Jason (University of Wyoming) [19] Ceramic Exchange and Community Interaction in the Late Prehispanic Cajamarca Basin, Northern Peru
Instrumental Neutron Activation Analysis (INAA) of a sample of both decorated and utilitarian ceramics from the site of Yanaorco illustrates possible patterns of ceramic production and exchange during the Late Intermediate Period (LIP; A.D. 1000–A.D. 1472). Yanaorco was a heavily fortified LIP village located overlooking the Gavilán Pass on the southern edge of the Cajamarca Basin. Measuring 14 hectares, it was one of the largest population centers in the region during the LIP. Excavation at the site recovered both elite and utilitarian ceramics in domestic and public contexts. Neutron Activation Analysis of a sample of 93 ceramic fragments recovered from excavated contexts has revealed patterns in compositional variation and homogeneity implying the local production of domestic wares and the possible import of many fine ware types, probably produced on pastes whose sources are elsewhere in the basin. These exchange wares are believed to have been produced at other LIP Cajamarca sites and brought to Yanaorco within so far not well understood exchange networks—possibly within the context of periodic inter-community events at the site. This strategically located community may have been a spatial nexus for broader regional activity.

[44] Architecture and Archaeology at 76 Draw
Excavations during the summers of 2009, 2010, and 2013 recovered over 80,000 artifacts and exposed architecture across 76 Draw, an Animas Phase site on the northernmost edge of the Medio period culture. Excavations were organized around 10 excavation units. A summary of the architecture and artifacts recovered from each excavation unit is presented here, including evidence for religiously and socially important features including extremely thick walls, platform hearths, and formal animal burials. Areas of the site display strong evidence indicative of looting activity, while other portions are less disturbed. These data taken together reflect integration with the larger Medio period world, especially the Ramos Zone that contains Paquimé and its neighbors. It also reflects integration with the larger Jornada Mogollon culture and the earlier Mimbres culture.

[191] Los juegos de pelota de Cancuén: un medio en el reforzamiento de la identidad cultural de un sitio fronterizo
New theories concerning the competitive processes of political and economic power are based on the concept of "networks of identity" formed between communities, groups and individuals. The impact of such networks may stretch between closely-placed sites or also to distant ones. Recent research at Cancuén, a site located on the edge of the lowlands and highlands of the Maya area, as well as other sites presented in this paper, have demonstrated that Maya ball courts were important locations for the formation and consolidation of interregional networks of power during the Classic period. These networks of interaction provide us with new insight about the nature of the border highland/lowland Maya communities and the limits of the power of the rulers of the reigns of the political systems of the Maya Classic period.

[213] Lost in Paradise: Placing the African Diaspora in the Danish West Indies/United States Virgin Islands
Diaspora research typically focuses on the maintenance of cultural traits of peoples from their points of origin. Equally important is the examination how displaced groups forged new social realities at their destination. In this paper we examine how individuals and social groups transitioned from enslavement to freedom on St. Croix in the Danish West Indies during the eighteenth century. Using archaeological data and historical records we trace trajectories of several African families and the legacies of those histories into the early 19th century. Ultimately we identify that the emergence of Crucian communities, as people and places, was intimately linked to the formation of local identities and the negotiation of
social and economic mobility within the contexts of Danish colonialism inasmuch as the "Africanisms" that are often the focal point of diaspora studies.

Torres-Rouff, Christina (UC Merced)

[143] Displaying Violence, Displaying Masculinity: Violent Injuries in Life and Death in Northern Chile’s Atacameño Oases

An understanding that violence is gendered pervades thinking about conflict. While violent actions are frequently attributed to men, these acts are not solely contingent on sex, but rather reflect social customs and practices. As a result, these acts of violence can have a performative element in the display of social identities, including masculinity. A close read of the remains of nearly 300 individuals from two Middle Horizon (A.D. 500-1000) cemeteries shows the intersection of gender, power, and violence. While women were not free of trauma, many men bore visible signs of violent engagement through an overwhelming bias towards direct confrontation reflected in sublethal facial fractures. Moreover, in life these individuals would have displayed these injuries in bloody form during conflict and afterwards in the misshapen appearance of their faces, clearly embodying the violence. Similarly, in death, individuals carried their weapons with them, wielding them as a form of power in the grave. Their conspicuous placement adjacent to the deceased suggests that they were clearly visible to the community during interment, a prominent part of the performance of the burial ritual. Together, these forms of evidence suggest the visible display of violence, in action and material, that was tied to masculinity.

[200] Developing regional Chronologies Using Ceramic Metatypologies: An Example from Northwest Mexico

The formation of the northern frontier of Mesoamerica has been studied from the point of view of several individual polities. A comprehensive, accurate understanding of how and why polities developed in this frontier zone during the Classic and Epiclassic periods (A.D. 200-1000) requires synthetic analysis. Synthetic analysis, however, requires a regional-scale chronology and a ceramic metatypology can provide the chronological control needed for accomplishing this task. The creation of a ceramic metatypology has recently been undertaken by a team of archaeologists working in seven occupation areas within the Zacatecas region of Northwest Mexico (i.e., the Malpaso, Bolaños, Tlaltenango, Juchipila and Verde Valleys, as well as the Chalchihuites and Ojocaliente areas). This paper presents the methodology used to develop a regional metatypology and “digital ceramoteca” housed on tDAR (the Digital Archaeological Record), as well as the preliminary results of an intensive workshop focused on documenting the timing and adoption of regional ceramic traditions and interpreting the chronological patterns of those traditions. The development and application of a ceramic metatypology to site assemblages will provide us with an understanding of the interaction dynamics within Northwest Mexico and their implications for the development of sociopolitical complexity in frontier zones.

[195] Terminaciones Rituales en los Principales Edificios de La Región Puuc

Durante las últimas exploraciones realizadas en varios de los principales sitios del Puuc, tales como Uxmal, Kabah, Sayil y Labná, hemos hallado innumerables evidencias de un tipo de destrucción intencional los edificios principales. Si bien los edificios prehispánicos fueron destruidos por diversas causas, algunos de ellos muestran huellas de destrozos que fueron realizados de manera cuidadosa y siguiendo un procedimiento similar en todos esos sitios, lo que nos ha permitido identificar un Patrón de Destrucción en que pudiera extenderse a la Región. Junto a estas destrucciones hemos hallado una serie de evidencias que nos permiten suponer que son el resultado de una actividad planificada y consensuada entre los individuos de tales comunidades prehispánicas.

Tostevin, Gilbert (University of Minnesota)

While accepting the multi-causal nature of most questions, archaeologists nonetheless often rely on the greater ease of testing single-cause hypotheses when the preserved material record indicates that an
adaptive advantage could have been afforded by one artifact form (or behavioral trait) over another. The identification of lithic morphologies among Aurignacian assemblages as suitable for specific projectile delivery methods, allowing greater hunting success, is a case in point. Yet what of other cases when the actual cause of an adaptive change in hominin life-ways does not preserve and is not so obvious? How is such an adaptive change recognized as having happened? Evolutionary Archaeology's close reliance on population-level evolutionary theory, including cultural transmission (CT) theory, increases the likelihood that such "invisible" adaptive changes can be identified through the recognition of cultural transmission events in preserved material culture that could have resulted from a coattail effect (or indirect biased transmission in CT terms) from adaptive changes in "non-preserved" behavior. The present paper discusses how a behaviorally-informed approach to cultural transmission within Evolutionary Archaeology can uncover new evidence of an adaptive change and population pulse associated with the Bohunician technocomplex during the Early Upper Paleolithic in western Eurasia.

[323] Watching for Roque: The Dendroarchaeology of La Jara Canyon, Dinétah

At dawn on August 11, 1705, Mre. de campo Roque Madrid led a force of Spanish soldiers, civilian militiamen, and Indian auxiliaries into Dinétah, the Navajo heartland. This invasion resulted in the destruction of Navajo hogans, burning of Navajo corn fields, torture and murder of Navajo women, and two battles with Navajo combatants. Spanish documents, including Madrid's diary, indicate that similar entradas regularly entered the area via La Jara Canyon, over the next decade and subsequently engaged various Navajo groups in violent encounters throughout the eastern portion of Dinétah. These same documents hint at the Navajo responses to Spanish aggression, but tell only one side of the story. There are no known Navajo oral traditions concerning these specific events. Archaeology and tree-ring analyses provide more detailed data concerning the nature of these early eighteenth century conflicts. This paper discusses the Navajo archaeology and dendroarchaeology of upper La Jara Canyon and illuminates Early Navajo responses to not only the Spanish entradas, but other conflicts as well.

[105] Going Vertical: Using Vertical Progression Techniques to Explore Complex Mortuary Spaces in Chachapoyas, Peru

Most archaeological practice involves horizontal excavations of ancient occupations and cemeteries, but the Chachapoya of the eastern montane of Peru, built spectacular mortuary structures along narrow cliff ledges and in shallow caves. The mortuary complex of La Petaca includes more than 80 platforms, modified ledges, mausoleums, and caves containing human remains across one section of an exposed rock face more than 200 meters across by approximately 80 meters high. While the site has been looted and damaged due to various taphonomic processes related to the vertical space (including cultural, geological, and biological), we argued that there are many important details of these constructions that could still be recorded, especially in relation to how the ancient Chachapoya people created and accessed these vertical spaces. Through collaboration with Spanish spelunkers, we were able to identify and access many of the different constructions using specialized repelling techniques; including industrial harnesses, secondary safety lines, pendulum connections, rebelay, and suspended platforms. This valuable partnership between spelunkers and archaeologists allowed us safe access to these exceptional contexts to map, sample, and make detailed observations of building methods and burial contents. This research was sponsored by the Petzl Foundation.

Trabert, Sarah (University of Iowa)

[323] Social Identity in Protohistory: A Case Study from the High Plains

During the Protohistoric period in North America, many Native American groups experienced significant social, economic, political, and demographic disruption stemming from the European colonization of their continent. Previous research on this colonization has long focused on areas where direct contact took
place between Europeans and Native peoples. This paper explores the indirect effects that colonization may have had on groups living beyond the borders of colonial control; principally on the central and high Plains. Topics such as demographic change, migration, ethnogenesis, hybrid communities, and social identity will be explored using Dismal River aspect sites as a case study. The sites and objects that Dismal River aspect people left behind exemplify the fluid and dynamic nature of Protohistoric social identity and show how archaeologists must complicate previously held concepts of cultural boundaries and intraregional interactions.

Trachman, Rissa (Elon University)

Economic Organization at the Site of Dos Hombres and its Hinterlands: A Multiscale Perspective in Northwestern Belize

Recent investigations at the site of Dos Hombres in northwestern Belize combined with previous research both at the site and its hinterlands reveal interesting preliminary evidence towards economic organization. Trade of material culture both in the site proper and the nearby households is evidenced through obsidian, shell, and ceramics. Hinterland occupation data indicate much about the ways in which households negotiated their material world, access to goods, and their fluidity related to both social status and chronology. Within the Dos Hombres site center, investigations of an Early Classic tomb revealed a stratigraphic lens of obsidian artifacts above the tomb architecture. Preliminary sourcing along with lithic technological analysis indicates that Dos Hombres was trading for percussion cores from the sources at El Chayal and producing prismatic micro-blades from those cores locally at Dos Hombres. Recent architectural excavations in the large open Plaza A of Dos Hombres have revealed common architectural elements with those seen at other sites possibly indicating the exchange of technology and the possibility of an eastern Peten regional architectural style. The result of the analysis at these different scales demonstrates heterogeneity of ancient Maya economic organization as it relates both to chronology, context, and social organization multiple scales.

Pioneering Archaeology in the Mountain State: The Career of Edward V. McMichael

Between 1960 and 1967, Edward V. McMichael served as the Head of the Section of Archeology at the West Virginia Geological and Economic Survey in West Virginia. As West Virginia State Archeologist, McMichael was responsible for surveying, documenting, and excavating archaeological sites throughout the state; however, the focus of much of his work was concentrated on the central and southern portions, particularly the Kanawha River Basin. Through collaboration with members of the West Virginia Archeological Society, McMichael excavated significant sites throughout the region including Mount Carbon Village and the Buffalo Site. Equally important were a series of salvage operations at numerous mounds in Boone, Kanawha, and Putname counties. Through these investigations, McMichael developed a chronological framework for the state, particularly the Woodland period, that has change little over the past 40 years. McMichael's contributions to the archaeology of West Virginia and the surrounding regions were significant and are widely cited today.

Trameri, Andrea (ISAW-NYU)

Preliminary Investigations at Kntk Hoyuk, Southern Cappadocia: Middle and Late Iron Age; Earlier Phases

The new chronology at Gordion and the recent investigations at Kerkenes are providing new insights into the archaeology of Central Anatolia during the Middle/Late Iron Ages. The first three years of archaeological campaigns (2011-2013) at the site of Kntk Hoyok, Southern Cappadocia (Turkey) have provided novel pieces to the puzzle, thanks to the investigation on the fortified citadel and the lower town. This presentation will focus on the Middle and Late Iron Age levels excavated on the summit and the slopes of the mound. The preliminary investigations show substantial material evidence for the Iron Age and a remarkably good degree of preservation of stone and mud brick architecture. Two contexts will be discussed within the presentation: the citadel fortification and a trash area on the N slopes. The important MIA fortifications of the citadel are extremely well preserved, and therefore a project of restoration was begun in 2013. A significant quantity of high quality material findings from the last campaign is associated with an area characterized by trash deposit layers on the N slope. The manufacture of uncommon animal shaped vessels and statues related to these layers, dating to the Achaemenid period, provide insights to a possible cultic practice.

[155] Life and Death in Rural Texas: Analysis of Biological Distance and Demography at Montgomery Hill Cemetery
The skeletal remains excavated and analyzed from Montgomery Hill Cemetery represent a rare opportunity to gain insight into the life and death of a previously unknown and undescribed group of individuals who lived along the prairie margin in rural Texas during the latter part of the nineteenth century. In 2011 and 2012 the skeletal remains and associated cultural artifacts from 25 graves were recovered from the Montgomery Hill Cemetery. The demographic composition of the cemetery is unlike any other previously excavated in Texas in that it is predominately composed of sub-adults, thus representing subset of the late 19th century Texas population previously underrepresented in bioarchaeological investigations—poor, rural children. The present work uses osteological data collected from those individuals exhumed from Montgomery Hill Cemetery to better understand the life and death of these people through demography and basic indicators of health and trauma. Dental metric and nonmetric data is utilized to investigate biological distance between individuals. Geostatistics and spacial analyses is used to aid in identifying potential family units. From this we may expand our knowledge of underrepresented sharecroppers and tenant farmers, and their families in rural east Texas in the decades following the 1865 emancipation of slaves.

Traugott, Joseph (Curator Emeritus, New Mexico Museum of Art)
[202] Re-Viewing Ancestral Pueblo Design Strategies
Linda Cordell was aware of the potential insights to be found through the study of design strategies and encouraged me to examine how design was used by Ancestral Pueblo peoples. While all pottery is both a work of art and a functional object, this is especially true for painted pottery. Ancestral Pueblo design motifs were often composed of paired, similar elements, in which unpainted negative space is as important as the painted elements that archaeologists have studied. This paired strategy created optical illusions that made the painted elements appear as backgrounds and the unpainted areas as the intended image. These optical phenomena have not been discussed previously. This design strategy cuts across pottery typologies and I describe it as “isomeric design” (Greek for “equal forms”). My research demonstrates that potters throughout the greater Southwest employed isomeric designs between CE 900 and 1350. However the use of isomers all but disappeared after major population movements throughout the region. In addition, I propose that “step and fret” or “lock and key” designs are actually simplifications of dual spiral motifs. This research would not have proceeded, or produced its unusual results, without Cordell’s interest and support.

Travina, Anastasiya (University of Texas at Austin), Anastasiya Travina (University of Texas at Austin) and Daniel Woodie (University of Texas at Austin)
The writing system of the Inca Empire was called khipu. Khipu is comprised of sets of yarn, containing numerous knots, which are tied along the length of the fiber. The patterns of khipu structure represent accounting and narrative information encoded in double-entry method of input. Using historical and statistical analyses, this paper explores non-numeric properties of colonial and Inca khipu preserved in several museums and published in the Khipu Research Database. We apply two non-parametric methods, correspondence analysis and Kolmogorov-Smirnov test, to studying such categorical properties of khipu as cord termination, attachment, and color. The paper also discusses the question of how environmental and preservation factors affected the shades of dye and what statistical methods could be used to address this issue. Finally, the paper attempts to understand the differences of these properties across various regions of the Inca Empire and hypothesize how the Incas were able to establish and monitor labor assignment and distribution through the Andes.

[68] After the Apocalypse—Engagement with Maya Cultural Heritage through Archaeology, Collections, and Museums
The world did not end in December 2012 with the turn of the Classic Maya calendar, and neither did the
challenges faced by archaeologists and museum professionals working to preserve the material culture and cultural legacy of Maya people. The need for archaeologists, along with others, to serve as public interpreters of cultural heritage is growing, especially given collections and sites around the world that remain endangered. Under pressure to economize in stewardship practices while increasing the impact and accessibility of collections for diverse communities, archaeologists are responding with innovative projects, collaborations and public programs.

Trein, Debora (University of Texas at Austin)

[224] Close the Door When You Leave: Termination Deposit at a Temple Structure at the site of La Milpa, Belize

This paper examines ancient Maya ritual termination practices in monumental contexts. These practices are understood to consist of commemorative events in which ritually and politically significant structures are abandoned, destroyed or buried. In particular, attention will be given to termination events that were quickly followed by site abandonment or reorganization. It is argued that a study of termination deposits may be used to understand the character of socio-political organization of communities on the cusp of major societal change. This examination will be illustrated by the material record present at Structure 3, a large temple building at the site core of La Milpa. La Milpa suffered extensive socio-economic instability at the end of the Late Classic period, which resulted in the large-scale dispersal of the population. Archaeological material uncovered in the 2013 excavations of Structure 3 suggests that this building was subjected to a complex set of termination events over an extended period of time immediately before the core of La Milpa was abandoned. These termination events entailed a considerable level of organization of labor and resources, which implies that the abandonment of La Milpa may have been a planned process that entailed some level of community participation.

[104] Early Horizon Fortified Settlements and Defensive Strategies in the Lower Napeña Valley, Peru

This poster examines patterns of defensive architecture in the lower Napeña Valley, north-central coast of Perú during the Early Horizon (800-200 B.C.). Results of systematic surface surveys and excavations at several sites indicate the increased importance of armed conflicts and intercommunity violence, mostly during the second half of the first millennium B.C. While warfare is likely to have played a major role in shaping local sociopolitical and ritual landscapes, spatial and architectural data have yet to be systematically collected and analyzed. This paper presents results of mapping operations at the centers of Caylán, Huambacho, and Samanco. Ancient conflicts are materialized in the presence of fortified walls, observation posts, and hilltop forts. The formal and spatial characteristics of these features are described to shed light on defensive architecture. Using GIS tools, we explore the distribution of defensive features, evaluate viewsheds, and delineate the intensity and direction of potential threats with the objective of understanding local defensive strategies.

Tremain, Cara (University of Calgary)

[164] The Art of Dressing: An Iconological Approach to Ancient Maya Identity

Outward appearances, as a visual form of communication, are one of the principle ways in which identities can be expressed. The exploitation of a wide range of materials and the ability to construct different dress styles allowed the ancient Maya to express identities in a variety of ways. Despite the hindrance that a humid environment plays in the recovery of direct evidence of organic dress materials, the wealth of pictorial evidence available allows for a reconstruction of identities expressed through dress. This presentation will outline a methodology for better understanding dress in the Central Maya Lowlands during the Late Classic period (600-900 C.E.), and will explore initial research results from several museum collection investigations.

[23] An Ideal Free Distribution Model for Hunters in Northern Alaska: Implications for Arctic Small Tool Tradition Coastal Settlement

A long standing debate in archaeology concerns the ranking of coastal verses terrestrial habitats. One
camp argues maritime resources are technologically expensive and riskier to harvest than terrestrial resources. The opposing camp argues that aquatic resources provide a greater amount of calories, fat and nutrients, and that the abundance and stability of these prey make coastal habitats more attractive to hunter-gatherer populations. This paper uses an Ideal Free Distribution model to rank coastal and interior habitats in northern Alaska. Ideal Free Distribution theory holds that animals colonize habitats with highest suitability first and only move into lower ranked habitats after competition reduces suitability of the first. My rankings are based on the sum of potential calories for all prey found in each habitat that is included in the diet. Seasonal fluctuations in prey population densities are estimated to refine rankings. I test the model by using radiocarbon dates from Arctic Small Tool tradition (ASTt) sites to determine 1) if the settlement patterns of northern Alaska by ASTt hunters follows predictions made by Ideal Free Distribution theory and 2) if ASTt coastal settlements post-date or coincide with occupations of interior habitats.

[252] Preclassic Ritual and Community at Ceibal, Guatemala: Excavations along the Center Axis of the E-Group in the Central Plaza of Group A

Our recent excavations along the center axis of the E-Group in the Central Plaza of Ceibal revealed that this space was a ritual focus of this community since its founding. Starting around 1000 B.C., caches were placed in this area until at least the Late Protoclassic, indicating the continuous use of this area as a public ritual space. However, changes in the configuration and contents of these caches show changes in ritual practices and regional interactions through time. While ritual practices in the Early Middle Preclassic seemed to be linked to those of sites in Chiapas and the Gulf Coast, by the Late Middle Preclassic Ceibal appears to have become part of the interaction sphere of the Maya lowlands.

[151] The Development of CRM and Its Relationship with Archaeological Collections Management

Archaeological collections and associated records are the raw data that endure from our scientific endeavors, not reports. The data we have gathered as professional CRM archaeologists over the past forty years are impressive. However, the care afforded these collections and records has been at best uneven, despite the comprehensive definitions, standards, procedures, and guidelines issued by the Department of Interior in 1991. Resources to care for the data, priorities of agencies and their personnel, private sector interests, public and private museum policy, and the attitudes of our own discipline have all shaped and contributed to the status and care of our national collections. However, in many areas of the nation there have been constructive and successful initiatives that have led to new approaches for care and access to large scale collections. Several successful curation paradigms developed over the last forty years include, regional curation approaches, engagement of the public/private sector, non-profit endeavors, and the use of Veterans. These approaches are successful because they have adapted to the changing landscape of interest in our cultural patrimony. Finally, the future use of our collections will most likely come from the public and education community, not purely researchers.

[77] Collections Crisis in the Nation’s Capital

The Washington, D.C. Historic Preservation Office (HPO) is dealing with a collections crisis over 30 years in the making. The HPO has no provision for a repository to curate collections generated from federal or local compliance projects. No City Archaeologists have made progress. Fiscal and physical realities have the HPO in perpetual reaction mode, hampering their ability for long-term curation planning. This poster outlines the current state of the collections crisis and ongoing activities to remedy the situation. While the HPO collections are organized and managed using a PastPerfect museum software database, they are physically spread across numerous locations that are environmentally uncontrollable. Some local federal agencies also fail to meet federal curation standards (36CFR79) or delegate curation to the HPO. One federal entity secretly discarded collections rather than curating them, forcing the HPO to verify the locations of collections from all previous archaeological surveys and determine whether the responsible agencies, federal or private, are meeting their curation responsibilities. In the process, the HPO has accepted collections that were marginally curated, and/or in danger of discard. We seek advice and suggestions from others who are dealing with their own collections crisis.
Trombold, Charles (Washington University in St. Louis) and Ryan Schuermann (Texas State University, San Marcos)

Maps created from archaeological field surveys are important records that reflect spatial and temporal interaction of features on a landscape. Historic maps, those created before development of GIS in the 1990’s, have the potential to be useful sources of spatial information. Assessment of this information includes an understanding of the relationship between map maker and map user, and the ability to quantify the data’s positional accuracy. In this paper, we examine two historic maps of the Malpaso Valley: the 1833 map of Carl de Berghes and the 1974 map by Charles Trombold. Through an analysis of variance (ANOVA) between five standard rectification models found in ESRI’s ArcGIS software, we compare the positional accuracy of site locations within the Trombold map to site location data acquired by GPS. We show that this process is paramount, yet potentially under-utilized in establishing confidence in quantitative analyses of landscape morphology and settlement location employing historic maps as a source of spatial data.

[234] Contextualization of Two Portuguese Museum Collections from the Marajó Island (Pará, Brazil)

The last two centuries saw numerous expeditions to the Amazonian Marajó Island which resulted in an impressive presence of Marajoara ceramics in museums worldwide. While the collection of material from the so-called “primitive” cultures was mainly done for comparative purposes in the 19th century, some of the 20th century collections represent clearly colonial or neocolonial practices. This poster aims to demonstrate the archaeological potential of the study of museum collections generally neglected by archaeologists due to lack of contextual information. It focuses on the past and present contexts of two Portuguese museum collections of funerary artifacts from the Marajó Island stored in Portugal. The methodology involves the creation of a descriptive catalogue with detailed drawings of the objects as well as functional and iconographic analyses based on parallels between these archaeological remains and archaeological data from current studies of the collection’s likely site of origin. Finally, an interview with one of the collectors provides new information on the non-scientific excavations. In sum, the compilation of all these lines of evidence allows us to contextualize these museum collections and increase our knowledge of the Marajoara culture.

[294] Results of the Ceramic Analyses from the New Mexico Department of Transportation U.S. 491 Highway Project in the Southern Chuska Valley, NM

Analysis of ceramic artifacts offers an avenue through which many questions pertaining to regional interaction throughout the Southwest can be addressed. The San Juan Basin was an incredibly active place in terms of social interaction and migration during prehistoric times, and ceramics recovered from sites in the southern Chuska Valley indicate that local groups had significant social and/or economic ties to other regions, such as the northern Colorado Plateau. Data recovery of more than two dozen archaeological sites by Statistical Research, Inc. as part of the New Mexico Department of Transportation US 491 highway project produced more than 60,000 ceramic artifacts. Ceramics analyzed represent a span of occupations from Basketmaker III through Pueblo III periods, and include wares and types from both local and non-local geographic contexts. This paper presents an overview of results from the ceramic analysis, and touches on interesting patterns and observations noted through time at the sites investigated.

Trubitt, Mary Beth (Arkansas Archeological Survey)

[30] Identifying Ceramic Exchange and Interaction between Cahokia and the Caddo Area

Historically, native peoples of Arkansas interacted with communities in the Southeast as well as in the Plains and Southwest. Ouachita Mountains novaculite, igneous rocks, and minerals were transported beyond the region during the Archaic and Woodland periods. Some movement of ceramic vessels took place during the Mississippian period, as shown by a growing body of studies of ceramic paste
composition using petrography and neutron activation analysis. Here, we focus on differentiating locally produced ceramics from non-local wares using instrumental neutron activation analysis (INAA). We compare fine wares from the Cahokia site in Illinois and the Caddo Area in Arkansas, Louisiana, Oklahoma, and Texas to address the question of the source of fine grog-tempered vessels found at Cahokia. Describing local ceramic traditions is a first step towards identifying technological styles and communities of practice in both the Central Mississippi Valley and the Caddo area. Explanations for interactions and the movement of ceramics that may include transport, trade, gifting, emulation, or migration, can then follow.

Trussell, Suzanne (Allegany Museum)

Wilderness Conquest: Community Development in Western Maryland in the Nineteenth Century

During the nineteenth century, aided by the development of transportation infrastructure, Western Maryland went from an isolated and densely wooded mountain area to a bustling town. The examination of the development of Mexico Farms from a large agricultural estate to a neighborhood highlights the shifts in land ownership, farming, ethnicities, and commercial access of Allegany County residents. A series of test units were excavated in 2011 to determine when a Greek Revival house in the neighborhood was constructed. The excavations encountered a thick, construction layer of shale capping two distinct features: a sandstone alignment and a thick brick fill layer as well as diagnostic artifacts from the 1820s-1830s. In addition, we analyzed 54 fragments of lead-glazed redware ceramic vessels. Interestingly, the tradition of redware pottery was carried from Germany, to Pennsylvania and by mid-nineteenth century had reached an industrial level of manufacturing in the Shenandoah Valley/Great Valley. The use of redware, despite the toxicity associated with lead glazes, shows a cultural tie to German heritage. This paper will discuss the cumulative investigations undertaken at Mexico Farms, detail the results of the archival history, and correlate how this neighborhood serves as a microcosm of rural Maryland in the early nineteenth century.

Levallois Origins and Variability in Africa

Levallois technology is an important component of many late Acheulian and Middle Stone Age (MSA) lithic assemblages across Africa. By 300 ka (and likely earlier), diverse Levallois methods were used by early Homo sapiens and ancestral taxa. Regional variation in the frequency and types of Levallois core preparation and flake production is central to many key arguments in human evolution. These include population dispersals out of Africa, inter-regional variation among MSA hominin populations, cognitive evolution and habitat preference. Current evidence is consistent with multiple independent origins of Levallois approaches to the production of flakes, points, and blades. However, whether Levallois variation results from population dispersal (as might be the case with the Nubian methods), population-specific approaches resulting from independent invention, isolation and drift, or adaptation to local environments needs to be tested. Doing so requires detailed technological studies of the Levallois concept at African sites comparable to those in Europe or the Levant and increased chronological control. Although data are fewer, the antiquity and diversity of Levallois lithic technology in Africa equals or exceeds that seen in neighboring Eurasia.

Differentiating between Residual Rickets and Osteomalacia: An Analysis of Existing Macroscopic and Radiological Techniques Using Three Post-Medieval Skeletal Populations

Vitamin D deficiency can manifest in the body depending upon the age of the individual. A vitamin D deficient child can develop rickets and carry the features obtained into adulthood, known as residual rickets. On the other hand, vitamin D deficiency in adults develops into osteomalacia. The manifestations of residual rickets and osteomalacia are similar; however, differentiation focuses on the presence of a few pathognomonic features. The identification of vitamin D deficiency in archaeological skeletal material provides important environment, socio-economic, and cultural information for past populations. Understanding the skeletal manifestations of residual rickets and osteomalacia will create a higher level of accuracy in diagnosis and differential diagnosis. Three post-medieval skeletal populations from the UK will be utilized in assessing previously determined macroscopic and radiographic techniques in identifying residual rickets and osteomalacia. This project assesses each pathological feature’s usefulness for diagnosis, as well as additional possible skeletal indicators. Results show residual bending as a key feature to identify residual rickets while the key features of osteomalacia are pelvic buckling deformities.
and pseudofractures. The pathognomonic features of residual rickets and osteomalacia manifest only in severe cases, therefore an underrepresentation of vitamin D deficiency in the archaeological literature exists.

Finding What Is Not Expected: The BaahKu Archaeological Project, Arroyo Seco, NM

BaahKu (LA 37627) is a small site within a privately owned one-acre lot, located near Arroyo Seco in the Taos Valley, New Mexico. Surface collections from archaeological surveys in the 1980s indicated a single pithouse/unit pueblo occupation in the northeastern quadrant of the site. Augering and test pitting in 2010, however, revealed evidence of occupation across the property. Further excavations from 2011 to 2013 at areas where no artifacts or cultural features had been identified on the ground surface, yielded roomblock and pithouse walls representing multiple occupations, as well as artifacts suggesting contact and exchange with other communities in the northern Rio Grande Valley. At the southwest quadrant, outside the bounds of surface remains, a possible shrine area was excavated containing flagstone capped turquoise, caches, and upright quartzite. The presence of extensive architecture and a possible shrine outside the area of the site where artifacts are visible on the ground surface indicates that traditional survey approaches may not be adequate for identifying important evidence of domestic and ceremonial activity. This paper discusses recent finds at BaahKu and reconsiders assumptions about the way we identify site size and settlement layout based on surveys and testing.

An Analytical Approach to Termination Ritual at the Classic Maya center of El Palmar, Campeche, Mexico

Termination ritual has been broadly reported throughout the Classic Maya centers, but its analytical approach needs to be refined. During fieldwork from 2010 to 2012, we recovered a large amount of termination deposits at the Guzmán Group, the north periphery of El Palmar archaeological site. In the field we documented the spatial context of termination deposits with a total station and plotted them on a map. In the laboratory we attempted to refit all recovered sherds and then analyzed their spatial distributions to examine whether vessels were broken in situ or elsewhere. Moreover, the maximum diameter of refitted vessels was estimated to assess if changes in vessel size are correlated with the transformation of the plaza. The results suggest that some vessels found after the remodeling of the plaza were designed for feasting and during termination ritual performers broke vessels in different places and brought these fragments to cast in and around the structures.

The Map of Cuauhtinchan II and the Valley of Teotihuacan

Since 1997 the Mesoamerican Research Foundation has investigated ritual cave use in Central Mexico relating to the Map of Cuauhtinchan II (MC2), a 16th century historical cartographic or ethno-geographic document. Extensive ground investigations over several years have allowed us to correlate locative glyphs (pre-Hispanic sites) depicted on MC2 with locations on modern maps. This presentation analyzes the northeast corner of MC2 along a line that begins in Veracruz on the north flank of Pico de Orizaba, and passes on the north side of La Malintzi to Atlihuexzia, Tlaxcala. The line then passes by the headwaters of the Rio Zahuapan, to pass by Calpulalpan. The important point is that, if our identifications are correct, the journey illustrated in MC2 begins in the Valley of Teotihuacan, not the Valley of Mexico. In other words, at the northwest corner of MC2, we enter the Valley of Teotihuacan and find a hill named Chiconautla - candidate for the legendary Chicomoztoc, Place of the Seven Caves. This hill is several miles west of the archaeological site of Teotihuacan.

A Summary of Excavations at a Late Archaic Coastal Shell Midden on Ossabaw Island, GA

Ongoing excavation of the Cane Patch site (9CH35) on Ossabaw Island, Georgia has provided new data on the deposition and formation of the site. Though much of the site was destroyed by shell mining in the 18th and 19th century, current excavations demonstrate substantial intact portions remain. Our investigations confirm the site is a Late Archaic mounded shell midden with a majority of decorated fiber tempered pottery. When compared to Late Archaic shell rings, shell mounds are relatively rare along the Atlantic coast and the social functions that resulted in their formation likely differ from those that formed the shell rings. The combined results of the 2011, 2012, and 2013 field seasons are compared to Crusoe and Depratter’s excavations in 1971. Though laboratory analysis of the artifacts and fauna is ongoing, new data from stratigraphic profiles, AMS dating, and LiDAR mapping are presented. Ultimately, these data may suggest the different social actions responsible for the formation of Archaic shell bearing sites along the Atlantic coast.

What is Cumberland? A Lithic Technological Organization Study

Cumberland fluted points are a distinctive full-fluted point form from the Midsouth United States, and are frequently recovered from a surface or disturbed context. Historically, they have been valued for their aesthetic appeal. However, Cumberland fluted points have received comparatively little academic study. As a result, there are many unresolved questions regarding Cumberland fluted point technology. What does Cumberland biface production look like in the archaeological record? Do Cumberland fluted points represent a discrete late Pleistocene point type with distinct morphological variability? Did the people who used Cumberland fluted points develop a unique settlement strategy, or did they exploit the same landscapes as people who used Clovis fluted points? The research presented here formally addresses the question, "What is Cumberland?" from the perspective of lithic technological organization and regional distributions.

Characterizing the Victims of Lethal Violence after the Collapse of the Wari Empire: Bioarchaeological and Isotopic Analysis of Massacre Victims at Huari, Peru

The decline of the Wari Empire led to significant increases in perimortem cranial trauma, indicating a rise in deadly violence. This study compares how those with perimortem trauma differed from those without perimortem trauma in terms of their skeletal health and isotope characterizations. We document carbon and nitrogen isotope ratios from bone collagen, and carbon and oxygen isotope ratios from enamel apatite. Preliminary carbon and nitrogen isotope data from bone collagen are statistically similar between adults with lethal cranial trauma vs. those without, suggesting that both groups had similar adulthood diets. In contrast, the carbon and oxygen isotope ratios from enamel apatite, which reflects childhood diet/water, are significantly different (T-test, p = .033; p = .011, respectively) between those with lethal head wounds (mean δ13C = -3.46; mean δ18OSMOW = 22.31) and those without (mean δ13C = -5.46; mean δ18OSMOW = 21.23). (Early forming teeth were used in both groups.) This suggests that those who died from lethal attack had distinct childhood experiences, at least in terms of diet and access to particular water sources. These differences were smoothed over in adulthood, but the childhood differences may point to distinct social or geographical groupings that could have had lasting impact in terms of who was targeted for deadly violence.

Tuomey, Joseph (US Bureau of Reclamation) and Ernie Rheame (US Bureau of Reclamation)

Perspectives on NGWSP from the Bureau of Reclamation:
The NGWSP has many interesting and complex components. Beginning a large, complex project of this sort required Reclamation staff to develop a number of new and/or different approaches to move the
project along. The San Juan Basin, where the project is located, has some of the highest archaeological site densities in the country. The project area is a patchwork of varying land ownership. Working on Reservation lands as well as on other federal agency lands meant Reclamation staff had to consider multiple requirements for submission of reports and consultation requests. We discuss some of the challenges we have faced and some of the lessons we have learned in the first few years of this twelve year undertaking.

Turck, John (University of Georgia) and Victor Thompson (University of Georgia)

Measuring the Impacts of Past Behavior on the Present Environment: A Case Study from the Georgia Coast

Although human activity may be restricted on or even absent from the landscape (e.g., due to migration, being wiped out by disease, the establishment of wildlife areas or national reserves, etc.), the effects of past activities are still felt on the present environment. Our case study from the Georgia coast reveals that 5,000 years of human behavior are still influencing the structure of the present ecosystem. Examples include depositing shellfish remains on upland surfaces, dumping ballast, dredging, certain agricultural practices (e.g., rice plantations), digging ditches, piling up soil, clearing fields, and building structures. Our findings have implications for studies of future environmental change, namely that the past must be taken into account to understand the present environment and make predictions about the future.

Contributions of Dendro-14C-Wiggle-Matching to Chronology at Epi-Classic Malpaso Valley Sites, Zacatecas, Mexico

The Epi-Classic is one of the most turbulent periods in Mesoamerican prehistory, and also one of the least understood. Theories to explain the mass movement of Mesoamerican peoples and their lifestyles into the north during this period, which include political disintegration in the Mesoamerican core, climate change in this arid region, and the development of exploitive activities and trade networks, are difficult to assess due to imprecise chronological control. This paper reports preliminary findings that simultaneously address the chronology issue, and set the stage to examine the climate change theory. We employ the “dendro-14C-wiggle-matching” method on existing collections of archaeological wood from La Quemada and Los Pilarillos, two Epi-Classic archaeological sites in the Malpaso Valley, one of the northernmost regions on the frontier. The wiggle-match method fits 14C dates, from tree-ring segments with a known number of rings, onto the 14C calibration curve, producing substantially more precise dates than radiocarbon dating alone. We illustrate the utility of this method, both for a cultural understanding of the sites themselves, but also as a way to understand settlement dynamics between this region and outlying ones.

Turner, Andrew (University of California, Riverside)

East Meets West: Borders and Boundaries in Central Mexico After the Collapse of Teotihuacan

The collapse of Teotihuacan, around AD 650, caused a ripple effect that lead to a reordering of borders, boundaries, and networks across Mesoamerica. Several polities, including Xochicalco, Cacaxtla, and Teotenango, emerged in Central Mexico to fill the vacuum left by the great Early Classic metropolis, and seats of power shifted to areas that had been politically marginal. While emulating and adapting certain conventions and practices established by Teotihuacan, these sites also claimed to have far-reaching ties to other parts of Mesoamerica. The authenticity and nature of their relationships to distant regions is a matter of debate, but it is likely that a network of social actors developed intraregional political and economic ties as a means of making claims to the power and authority that Teotihuacan had. Interpolity relationships and trade agreements were solidified through the institution of a religious ideology, a suite of iconographic conventions, and a common writing system that superseded ethnic affiliations and territorial borders. This ideology emphasized a division of eastern and western regions in Mesoamerica as a primary means of organizing the broader cosmos. This division is also mirrored on a microcosmic scale in the site plans and features of these emergent polities.

Turner, Michelle (Binghamton University)
[56] Frontiers Reconsidered at Chimney Rock
Recent archaeological theory, drawing on work in other social sciences, is redefining the notion of the frontier. Theorists increasingly recognize that contemporary understandings of frontiers and borderlands, structured by colonialism generally and by the American experience specifically, may not accurately reflect the reality of such places in prehistory. In particular, archaeologists have begun to question traditional notions of an active, dynamic core and a passive periphery. The Ancestral Puebloan community of Chimney Rock Mesa lies at the northern frontier of the Chacoan world. Archaeologists have often viewed the site as a place where a preexisting local community faced an influx of people from distant Chaco Canyon, whether as invaders or as welcome new arrivals, and where society was transformed as Chacoan ways and ideologies arrived. This paper reconsiders Chimney Rock, long seen as an example of Chacoan hegemony, as a case study for reevaluating traditional core-periphery understandings of this region. It seeks to reposition Chimney Rock as a place where indigenous traditions persisted alongside Chacoan ways, as a locale of syncretic development, and as a frontier community that may have had a profound influence on Chacoan society.

Turner, Katie (Indiana University of Pennsylvania)

[233] An Examination of Late 18th Century Forts: A Pennsylvania Typology
As battlefield archaeology continues to grow in interest, there are an increasing number of topics that must be addressed. Likewise, as professionals discover that battlefield archaeology is more than examining the nation’s historic battlefields the demand has arisen to study other components of conflicts. One such component is the study of forts, and the key role that these structures played in battles and conflicts. To date, no typology of Pennsylvania forts has been completed so for the purpose of this study only forts from Pennsylvania will be examined. To fill this void research will be conducted to develop a typology of late 18th century forts. This typology will examine roughly 60 forts from the French and Indian War and the Revolutionary War. Some of the attributes included in the typology will be the plan and layout of the fort, duration of occupation, purpose for the fort’s construction, location of the fort, access to trade networks, and construction materials. A comparison will also be conducted in an attempt to understand the evolution of forts.

Turner, Sara (Georgia State University) and Niels Lynnerup (University of Copenhagen)

[241] Dietary Patterns in Holbæk, Denmark during the Medieval Period
The medieval period in Denmark (11th-16th century) was a time of great social and economic change. In this paper I discuss the dietary patterns of individuals from a medieval site in Holbæk, Denmark who lived during this historically dynamic period. This study compares existing isotopic data with collected data from dental macrowear and caries in order to provide a more complete picture of diet and subsistence patterns of these individuals during their latter years. Specifically, changes in dietary patterns are analyzed pre and post the Black Death (AD 1348-1350) due to historical evidence of changing food and agricultural systems in medieval Denmark that occurred after the plague. The demographic decline greatly reduced the production of grain in Denmark, and supposedly diets became more reliant on livestock and animal products. Results suggest that there was a surprising lack of change in diet over time that run counter to expectations given the historical record. This study contributes a better understanding of human variation in medieval European populations.

Turner-Pearson, Katherine (Central Texas Archaeological Resources)

[231] The Stone Site (41ML38): A Contact Period Waco Indian Village Frozen in Time
The Stone Site (41ML38), referred to as “El Quiscat’s Village” by Frenchman turned Spanish Explorer, Athanase de Mézières, is located on the horseshoe bend of the Brazos River, north of present day Waco, Texas. It is the last remaining of several documented Waco Indian village sites in the area in the 1770s. The personal journal of de Mézières confirms his visit to the village in 1772, 1778, and again in 1779. But in 1786, the explorer found the village abandoned. All the other known Waco Indian village sites have been destroyed by urban expansion, while this site remains relatively untouched; this gives archaeologists a rare chance to study the impact of European contact over a short time frame and the lifeways of an aboriginal group that is somewhat obscure. While studying the archaeological record of both trade and native made goods from the site, researchers found almost equal amounts of French and Spanish goods, including large quantities of weaponry parts as well as articles for ornamentation. But as important as the trade goods recovered, was the lack of certain objects such as pottery and cookware.

Tushingham, Shannon (Washington State University) and Robert Bettinger (UC Davis)
[316] **Why Foragers Choose Acorns before Salmon: Storage, Mobility, and Risk in Aboriginal California and Beyond**

Despite the enormous potential of anadromous fish, foragers do not mass extract and store salmonids until very late in the archaeological record of California. Acorns, by contrast, were intensively used quite early in the record. Salmon are traditionally viewed as a low cost, high ranking resource, and acorns as a high cost, low ranking resource. The question thus arises: why were salmon not used and stored en masse much earlier? We offer a solution using a simple foraging model—the front-back loaded model—that distinguishes resources on their storage capabilities as well as overall cost, making it possible to calculate the risk of resource caching, which appears to have delayed intensive salmon procurement in California and the southern Pacific Northwest Coast.

[194] **Coping With Abundance: The Challenges of a Good Thing**
Abundance may be a generally good thing, but in a delayed-return society with any pretense to egalitarianism it also brings myriad challenges. Individuals or groups who produce or acquire an abundance of resources must determine how to physically preserve and/or socially deploy that abundance, while maintaining at least some appearance of equality and integration with other members of society. In this paper we explore possible strategies for coping with resource abundances at Neolithic Catalhoyuk in central Anatolia: these strategies plausibly included concealment, dispersal within a production group, and distribution across broader segments of society.

Two Bears, Davina (Indiana University, Doctoral Student)

[230] **Intertwined Histories of the Navajo and Japanese at the Old Leupp Boarding School Historic Site**
This poster will delve into the intertwined histories of the Navajo and Japanese that occurred at the Old Leupp Boarding School Historic site in the first half of the 20th century. The Old Leupp Boarding School was built to address the United States Government’s treaty commitment to support the education of Navajo children. Later, after the closure of the Old Leupp Boarding School due to flooding by the nearby Little Colorado River, it was re-used as a Japanese Isolation Center during World War II to imprison innocent Japanese American citizens. The intertwined and complex histories of both the Navajo and Japanese at the hands of the U.S. Government will be revealed and explored in the context of the Old Leupp Boarding School Historic site.

[249] **Fifty Years of Obsidian Sourcing in the Central Mediterranean: Quantitative Assessment of Transportation Routes, Chronological Changes and Intra-Site Variation**
Since early studies indicated that the four island sources in the Central Mediterranean could be distinguished by their elemental composition (Cann & Renfrew 1964; Hallam, Warren & Renfrew 1976), considerable research has been done on the geological sources; many obsidian artifacts have been analyzed; and socioeconomic interpretations made about transportation routes, chronological changes, and intra-site variation. Following my detailed studies of the sources, obsidian artifacts may be attributed to specific subsources on Lipari (2), Palmarola (3), Pantelleria (5), and Sardinia (7). Artifact analyses have been facilitated by the use of a portable non-destructive XRF spectrometer, which enables analysis to be conducted in museums and storage facilities, while decreasing the per sample cost of conducting such research. Overall, I have analyzed nearly 5000 artifacts, with at least 10 each for 90 sites in Sardinia, Corsica, peninsular Italy, Sicily, Malta, and Croatia, and along with the 3200 analyzed by other scholars. This large data set enables interpretations to be made about issues such as source access and territorial control, craft specialization, and the modes, frequency, and directions of material movement. Furthermore, this supports socioeconomic hypotheses made at both small and large scales, as well as addressing changes over time and space.

Planorbids, People, and Paleolakes: Freshwater Molluscs and their Implications for Late Pleistocene and Early Holocene Human Occupation

No other locality in California has produced as large and diverse a record of terminal Pleistocene and early Holocene human occupation as the China Lake Basin, northwestern Mojave Desert. Recent research conducted on behalf of the U.S. Navy at Naval Air Weapons Station China Lake has revealed a robust record of early human use. Why this small basin harbors such a record, and numerous other larger and better-studied basins in the Mojave Desert do not, can only be resolved through a detailed understanding of the paleoenvironment and the types of subsistence resources which may have attracted early foraging groups to China Lake Basin. In this talk, we use various kinds of mollusks to examine the paleohydrology and pluvial lake history of China Lake Basin during the terminal Pleistocene and early Holocene and discuss implications for the timing and nature of the earliest human occupation in the northwestern Mojave Desert.

Ulewicz, Kaity

Pyramids and Households during the LIP at the Lurín Valley: The Case of Panquilma

The focus of my paper will be one of comparative analysis from both Sector 1 and Sector 2 of the site Panquillma; focusing on the differences between building styles, settlement patterns, and spacial distribution between public and domestic areas. I will be identifying, comparing, and contrasting the elements mentioned in order to better understand the distribution of wealth between these areas, and to also hold a greater understanding for the economics of the area.

Ullah, Isaac (University of Pittsburgh, Center for Comparative Archaeology)

From a World of Compasses, Paper, and Pencils to the Digital Era: How to integrate “Pre-GPS” Survey Data into a Modern Research Paradigm

Early archaeological surveyors collected site location information using mental feature matching, triangulation, and estimation with manual survey instruments, topographic maps and/or raw aerial photos. Despite their (not insignificant) level of technical expertise, site coordinates recorded in that era are subject to a host of errors that make them seemingly incompatible with the kind of high resolution GIS-based spatial analyses that are common in modern landscape-scale archaeological research. The data recovered from early surveys, however, are vital components of the archaeological record for many regions around the world, especially in regions not currently accessible due to political instability or diplomacy. Furthermore, they may contain the best – or only – record of sites that have since been damaged or destroyed. What, then, should be done with older survey data? Using the site location data from the "pre-GPS era" Wadi Hasa Survey (undertaken by Burton MacDonald in 1979-1982) and the "GPS era" Wadi Hasa North Bank Survey (undertaken by Geoff Clark in 1992-1993) as case studies, I present a GIS-based routine that "reconstructs" and corrects (as much as possible) locational errors in early survey data, so that they may be integrated in a research agenda requiring high precision site location information.

Health and Diet in the Late Mesolithic: A Paleobiological Perspective through the Analysis of the Human Skeletons Retrieved from the Cabeço da Amoreira Recent Excavations

The archaeological work that took place in 2011 and 2012 in Cabeço da Amoreira Muge shellmidden uncovered three human skeletons: an infant and two adult individuals, a male and a young female. In this
paper we will present the results of the anthropological and isotopic analysis and highlight the possible inferences that can be drawn in what concerns health and diet. Caries and some physiological stress indicators, such as dental enamel hypoplasias and cribra orbitalia were observed on the female individual. Severe dental wear, trauma and osteoarthritis were noted on the male. The carbon and nitrogen stable isotopes of bone collagen points to a mixed diet of marine and terrestrial origin, with a slight predominance of marine resources, in accordance to the site location, in close proximity to the coeval Tagus estuary.

[294] Architectural and Household Evolution along the Southern Chuska Slope
Domestic architectural change through time has been observed to be an important window into larger social, political-economic, and ritual venues. Across time and space, the transition from round or circular, below-ground structures to rectangular or square, above-ground structures is seen as representative of fundamental changes in household economic and social organization. At the same time, some aspects of former architectural styles persist. Our paper focuses on this transition and persistence from the perspective of a sample of households dating between the Archaic and Pueblo III periods investigated as part of the US Highway 491 project. Through a close examination of domestic activities and structure function using architecture, floor assemblages, and features, we will develop models of the processes involved in this important, pan-cultural phenomenon, via a perspective from the American Southwest.

[261] An Empirical Test of Shell Tempering as a Proto-Hominy Processor
It has been argued that the shift to maize based diets across much of the Eastern Woodlands ca. A.D. 1000 was the primary catalyst for the rapid population increases, technological innovations, and fundamental shifts in social and cultural organization characteristic of Mississippian and Upper Mississippian peoples. However, raw maize kernels alone are known to be a nutritionally inadequate subsistence staple. Nixtamalization, or the alkaline processing of dried raw maize to produce hominy, yields a more readily digestible and therefore healthier food resource. Such processing is ubiquitous amongst maize-based societies in the Americas. The timing of the shift to maize agriculture was also closely associated with the adoption of shell tempered ceramics. As a result, the hypothesis has been offered that burned and crushed mollusc shell aplastic may act as an alkaline agent in a proto-nixtamalization process. The research reported here provides a formal empirical test of this hypothesis, and an evaluation of shell tempering as a potential hominy processor.

[65] LIDAR and the Structure of an Assyrian City: A Case Study from Erbil, Kurdistan Region of Iraq
Urban structure presents a tremendous challenge to traditional excavation techniques, so a variety of digital remote sensing applications have been brought to bear in recent years. LIDAR has been particularly successful. It has mostly been used to strip away vegetation to reveal subtle topographic traces in tropical regions. In this case study, an ancient city is obscured not by trees but by the buildings of a modern city. The Assyrian provincial capital of Arbil (ca. 900-600 BC) is nearly completely buried beneath the man-made features of modern day Erbil, capital of the Kurdistan Region of Iraq. LIDAR collected over the Erbil has presented the opportunity to strip away the modern city. We co-register the LIDAR-derived surface model with high-resolution satellite images and topographic maps to identify "bare earth" locations in a semi-automated fashion. These locations are used to interpolate a terrain model devoid of modern structures. Methods and representation in topography, ortho-rectified aerial photos, remote sensed imagery, and computational modeling enable collaborative research to reconstruct the shape and extent of this ancient city. Preliminary results are presented.

Discriminating Warp- and Weft-faced Plainweave Textiles without Edges: A Guitarrero Cave Test Case

Situated in the Andean highlands of Peru, Guitarrero Cave, has yielded a large array of perishable artifacts that span more than 12,000 years of human occupation. Included are the earliest directly dated textiles in the Americas as well as the putatively earliest examples of plainwoven cloth from the Andes. The latter technology, dated as early as about 8,100 cal B.P., provides the foundation for the later and technically more sophisticated textiles that prehispanic Peruvian weavers are renowned for. The earliest plainweave fragments from Guitarrero lack selvages, however, and so a consensus as to whether the pieces are warp- or weft-faced has been elusive, blurring our understanding of the mechanics of production of these early fabrics and the development of this weaving technique. This presentation reports the results of the direct AMS radiocarbon dating of some of the earliest plainweave fabrics from the site combined with metric and experimental analyses undertaken to assess whether warp- and weft-faced plainweave fabrics lacking selvages can be differentiated. The study’s results enhance our understanding of the chronology of a major Peruvian weaving technique and may contribute to our ability to differentiate warp- and weft-faced textiles in the absence of edges at other archaeological sites.

Whose “Border,” Whose “Periphery”? Looking at the Maya World from Southeast Mesoamerica

Core-periphery models often assume that the movement of ideas and materials between cores and peripheries is largely dominated by the former. Border studies, on the other hand, suggest that core-periphery dealings occur in permeable zones where members of various groups interact, creating novel cultural configurations. While power differentials may figure in these encounters, there is no assumed directionality in the flows nor is it likely that core-periphery interactions will yield similar cultural consequences even in neighboring areas. A similar position is advanced by interregional interaction perspectives. Allowing for the creativity and diversity of cross-border interactions is one thing, describing and explaining them based on archaeological remains is quite another. This paper examines the diverse natures and cultural outcomes of past interactions processes involving agents of so-called cores (in this case the Classic period [600-900 CE] Maya) and indigenous societies in four areas of Southeast Mesoamerica: the middle Ulua, lower Cacaulapa, and Naco valleys of northwest Honduras and the lower Motagua valley of northeast Guatemala. Attention is specifically paid to the models or theories that may best account for similarities and differences in these processes.

The Cholula World View and Tlaxcallan in the Postclassic

Historically, our vision of the Puebla-Tlaxcala Valley in the Postclassic has been strongly colored by the chroniclers’ obsession with Quetzalcoatl as a Christ like figure, revisionist nationalistic histories that portrayed the Tlaxcalteca as traitors, FR from a marginalized colonial Cholula recalling its “glorious past”, an unexplainably enormous pyramid, and wild speculation. The result of which has contributed to a Cholula-centric vision of this region during the Postclassic. Yet recent work at Tlaxcallan makes necessary a reassessment of the comparative importance of Cholula, as well as the nature of regional-scale economic, political, and ideological processes during the Late Postclassic. In this paper, we present new data from Tlaxcallan that indicate that Cholula may not have been the largest nor most important city in the Puebla-Tlaxcala Valley at contact and consider the implications of these findings at the regional scale.

La cerámica incaica del norte de Chile: actualización y perspectivas
A mediados de 1970 surgió la conocida discusión si el dominio incaico en el norte de Chile había sido directo o indirecto, a partir de la aplicación que se hizo del modelo de Murra. De acuerdo con esta propuesta, la situación se dirimiría en términos de que cuán abundante era la materialidad del Inca, especialmente cerámica, en los territorios conquistados y cuánto se atenía ésta al estilo del Cusco. De acuerdo con las incipientes investigaciones de aquella época, predominó y mantiene cierta vigencia la hipótesis de la ausencia de una conquista propiamente tal y que más bien se trató de un dominio indirecto. Aprovechamos este simposio para discutir estos planteamientos a través una síntesis y actualización de nuestros estudios sobre la cerámica incaica, aportando con nuevos datos estilísticos, tecnológicos, funcionales y cronológicos de Arica, Tarapacá y Atacama.

[291] Identifying Kinship Patterns in Anabaptist Cemeteries: Modeling Archaeological Graveyards

Archaeological theory suggests that the relative spatial locations of individuals in cemeteries can convey information about kinship, but opportunities to test this have been rare. To understand how relationships influence burial placement in cemeteries, modern and historical Anabaptist cemeteries in Central Pennsylvania were surveyed. By matching individuals to historical records, we find that the main determinant of burial location was the location of spouse, parent, or other members of the household. Since households are organized by kinship, patterns of shared patrilineages and matrilineages appear in the cemetery. To determine how these patterns could be interpreted in archaeological contexts where basic skeletal information (age and sex), fairly reliable ancient DNA markers (Y chromosome and mitochondria), and burial coordinates are available, we assigned these attributes to the known burials from three Anabaptist cemeteries. Using SatScan (www.satscan.org), a freely available program originally written to interpret epidemiological data, we were able to identify clusters of related individuals, and, in some cases, households. Larger cemeteries and those used over a century had fewer individuals who were found in kinship clusters. These methods could be used to identify related individuals in archaeological contexts, especially in smaller cemeteries.

Usherwood, Elizabeth (University of Massachusetts, Amherst)

This poster is the culmination of my undergraduate senior thesis research, which uses a case study of Luis Fatio Pacheco’s homespaces, or the places he would have considered home, to argue for a new methodological approach in historical archaeology. Through a multisited spatial biography, this research was able to trace Pacheco, a 19th century African American male, through time and space. By understanding how this individual how lived and moved through the world, this research illustrates how methodology can contribute to a vindicationist approach of African Diaspora archaeology while simultaneously illuminating the historical record. Through this case study, I argue that such methodology enables us to connect individual life experiences to the larger collective memory of “African America.” Moreover, utilizing a multisited spatial biography alludes to the dynamic movement of the past by eliminating site boundaries through a landscape approach while also exploring multiple places as connected through an individual’s experiences.

Usman, Aribidesi (Arizona State University)

[108] Recent Archaeological work in the Niger-Benue Confluence, North Central Nigeria

The Niger-Benue Confluence is an ethnic frontier zone of approximately 200 km2. The region is home to a number of different ethnolinguistic communities including the Igala, Yoruba-Okun, Ebira, and smaller groups like the Nupe, Kakanda, Gw’ari and Bassa-Nge. The Confluence has had a long history of trade, immigration, slave raiding, overlordships, resettlement, and intermarriage, making it a very complex social and cultural landscape. The Igala, located east of the Confluence, were middlemen in the exchange of the products of the forest and savanna regions. This situation is thought to have stimulated the formation of states in the area in ways similar to the emergence of kingdoms in the Western Sudan. My research is aimed at understanding the network of interaction that tied together many of the communities in the Niger-Benue Confluence and how it changed through time. A fieldwork program combining oral-ethnohistoric and archaeological data will allow for an assessment of local sociopolitical organization – a necessary step toward understanding regional interaction. Our recent work in Idaho, the political center of the Igala kingdom, provided the first attempt at addressing these issues. This paper reports the recent
archaeological work at Ojuwo Atogu and Okete Kakini sites in Idah.

Continuity and Change in Warlpiri Practices of Marking the Landscape

Drawing on long-term ethnographic research in Aboriginal central Australia, this paper explores how, when and why Warlpiri and neighboring people mark the landscapes within which they live. A primary concern of the paper is the dynamics of change in landscape marking. As is well known, cosmological significance was, and continues to be, inscribed in topographical features—including rock formations, hills, watercourses, trees and other forms of vegetation: potentially all are signs in this religious landscape. Physical markings of the land ranged from stone arrangements and rock art to more temporary markings, for example, footprints, fire scars, ceremonial ground paintings, branches placed at strategic points to indicate direction of travel and/or areas to which spatial prohibitions applied. Whilst customary ways of marking country endure, transformations also have occurred as a result of factors such as sedentarisation, people’s adoption of new technologies and thus new modes of inscription, changes in practices of memory and mobility, and modifications to the landscape made through the establishment of European infrastructure. Attending to continuities in people’s socio-cultural practices through time, the paper will consider the relationship between ancestral and contemporary Aboriginal practices of marking landscape in the creation of meanings in place and management of space.

Monumentalizing Solar Zenith Events at Cerro Maya, Belize

Since Cerro Maya was first excavated in the 1970s, its Late Preclassic architecture has been analyzed symbolically in order to comprehend ancient Maya cosmology and its relationship to kingship. While symbolic approaches have enabled understanding of Maya ideological systems, they tend to isolate archaeological features from their local landscapes. Using 3D visualizing techniques together with an approach inspired by North-Whitehead and Latour, I consider Structure 5C-2nd and the surrounding landscape as “events” that were expressed differently through varying practices each year, while generating historical significance over time, creating a palimpsest. 5C-2nd and other built and natural landscape features are better seen as an assemblage of local, historical, social, material, and temporal relations, none of which can be understood in isolation. Between 50 BC-AD 150, Structure 5C-2nd marked a point on the landscape where the first biannual solar zenith event was observed through a conjunction of landscape features. Structure 5C-2nd can be viewed as a generative event that created a set of temporal and historical relationships between people and landscape that played a significant role in the eventful process of rapid monumental construction at Cerro Maya’s site core.

Relating Aquatic Imagery and Themes in Late Postclassic Maya Contexts to Creation Mythology

Although fishing is not commonly portrayed in Late Postclassic Maya sources such as painted codices and murals, aquatic themes and offerings of fish do occur relatively frequently, and stingray spines are a common component of bloodletting rituals depicted in Late Postclassic contexts. Moreover, several deities seem to have a special connection to the sea, including the rain god Chaak and the elderly creator deity Pawahtun. This paper examines the relevant iconography and hieroglyphic texts and places them within the context of creation mythology related to the birth of the sun and the moon, and of the present race of humans.

Daring to be Different: Aztec Tula and the Triple Alliance's Relationship with Its Northern Hinterland

Although the archaeological site of Tula, Hidalgo in Central Mexico is best known for its early Postclassic Toltec fluorescence, recent ceramic analysis has revealed chronological and socioeconomic insights into Late Postclassic Aztec occupation of the Tula archaeological zone. Comparisons of Aztec III/IV black-on-orange design elements found on pottery at Tula, with those typically found at sites in the North and South Basin of Mexico, were successfully employed to distinguish Tula’s unique design elements. Subsequent analysis of the predominance of "Tula-style" designs suggests that Aztec Tula had a dynamic economic and political relationship with Tenochtitlan. Using these data, I will explore the diachronic nature of these dramatic changes in the Triple Alliance's relationship with its northern hinterland.

Finding Community in the Contrasts: A Bioarchaeological Methodology for Theorizing Community

Archaeologists in search of past communities must move beyond the identification of shared practices, and towards understanding the way that shared practices created social differences between groups. Contrasting patterns in aggregate data sets show where individuals’ narratives of place, practice, and history were woven into complex social landscapes. Bioarchaeological methods offer unique access to individual life histories, and therefore provide essential tools for understanding the ways in which bodies were referenced in the construction of community. A bioarchaeology of community must begin by finding the shared references, the correlations between data sets, and then identifying contrasting patterns of variation. Presumably produced by enduring practices of social differentiation, such contrasts between groups must be linked to broader archaeological contexts if their past social meanings are to be understood. Methods of biogeochemical provenience can prove especially useful by connecting communities to particular source regions. Once contrasting communities are associated with histories of place, past perceptions and goals can be theorized and models of archaeological communities can be operationalized as political, economic, and cultural interactions with material outcomes. An Indus Civilization case study using isotopes of lead and strontium is offered in support of the proposed methodology.

Valentinsson, Signe (Hunter College), Matthew C. Sanger (Columbia University, American Museum of Natural Hi) and Anna M. Semon (University of North Carolina at Chapel Hill, Ameri) [10]  
Large-scale pXRF Survey of Archaeological Ceramics from the American Southeast

While the chemical analysis of pre-Contact ceramics from the American Southeast has been an important research direction for more than three decades, on the Atlantic coast it has been deployed irregularly as it is often prohibitively expensive and destructive. The development of portable X-ray fluorescence (pXRF) technology, particularly the increased resolution and sensitivity offers an opportunity to conduct large-scale surveys of archaeological assemblages without significant destruction or financial expenditure. In this study, we use the newest generation of pXRF technology to analyze the chemical makeup of a large collection of pre-Contact ceramics from multiple sites located on the Georgia coastline. This poster discusses the advantages and disadvantages of using pXRF as a tool for surveying large assemblages and recognizing broad chemical patterns across time and among site collections. Interpretations of past social conditions and events are also offered, along with suggestions for future research. The results of this research are both of broad interest as they offer a critical test of an important emergent technology, as well as being locally relevant as they speak to regional questions of trade, migration, and developing social institutions.

Vallieres, Claudine (University of Florida) [38] The Role of Camelids in Tiwanaku Society: Human-Animal Relationships within the Private and Public Spheres of an Andean Urban Center

This presentation examines human-camelid relationships at the ancient urban center of Tiwanaku (c. AD 500-1100), in the highlands of Bolivia. Camelids participated in the production and reification of Tiwanaku’s status as a ritually-charged center with a widespread sphere of influence. They were integrated in ceremonial events, ingested through daily culinary practices and integral components of the surrounding landscape. Results from the recent faunal analysis of excavated contexts from the Akapana Pyramid, a central monumental feature of the site, are presented and compared to faunal data from the non-elite residential neighborhood of Mollo Kontu. It is suggested that through their multiple roles in spectacles and ceremonies, camelids were entrenched in Tiwanaku’s emblematic ritual life, while the use of their products in all aspects of daily life wove these animals into a sense of local identity for the urban residents. A look at the roles camelids held in both the private and public spheres at Tiwanaku blurs the common conceptual line between the ritual and the mundane and paints these animals as socially valued components of Tiwanaku’s urban landscape and identity.

Van Den Bos, Elisha (VU University Amsterdam) [127] (Re)building Histories: House Replacement and Intergenerational Strategy in the Neolithic of Western Anatolia and the Southern Balkans

In a sense, the Neolithization of the Eastern Mediterranean is a subject where grand narrative and daily life meet: while the temporal and spatial scale of the story of the expansion of farming from the Near East to the Balkans seems far removed from the scale of human experience, in recent years scholars have increasingly referred to the Neolithic as a ‘way of life,’ incorporating ideas about domesticity, households, and the social organization of settled communities. While this seems a welcome shift of focus in a field otherwise very much preoccupied with the big picture, this terminology in fact obscures regional variability between Neolithic lifestyles. The challenge for Neolithic studies is to make a more explicit connection between changing pathways of Neolithization and the short-term and local histories of Neolithic communities, which in the end inform us about what a Neolithic way of life actually entailed. In this paper I explore the possibility of using settlement and architecture as a temporal and spatial framework for studying variable Neolithic lifestyles. I suggest that house replacement practices constitute particularly significant moments in time, which evoke ideas about choice, durability, mobility and sedentism, social reproduction, and the variable pace of change.

Van Der Leeuw, Sander (SHESC) [75] Learning from the Past, but for the Future

The paper will make the argument that archaeology's long-term, material culture and environment
oriented perspective is essential to the design of a sustainable future for Earth, but that in order to optimize the impact of archaeology, we need to shift our perspective from a, a-posteriori or ex-post perspective (looking back in time) to an a-priori or ‘ex ante’ perspective (looking forward in time). This requires a shift in thinking from cause-and-effect and ‘certainty’ to ‘possibilities, probabilities, and unintended consequences. The paper will illustrate this mainly based on European archaeology, but with examples from elsewhere included.

[237] The Day the Lizard Died

My career as a Southwest archaeologist is Jim Neely’s fault. I studied Southwest archaeology with Dr. Neely as an undergraduate at the University of Texas from 1982-1986. It was Jim Neely who first put a trowel in my hand and a New Mexico green chile enchilada on my plate. It was Jim Neely who first took me to Chaco Canyon. At the WS Ranch Site, I excavated in a great kiva, dug a trash-filled pueblo room, and hiked across wilderness mountains in a county with more bears than people. Watching Jim, I learned how a liberal archaeologist could navigate successfully within a politically conservative landscape where many locals had little use for archaeology beyond the dollar value of a looted pot. First field experiences are formative field experiences, and just about everything I’ve ever accomplished can be traced in some way back to my time at WS Ranch. And once I’d graduated, it was Jim Neely who inspired me to enter the doctoral program at the University of Arizona, because that’s where he had gone. I offer this brief homage in gratitude for Jim’s mentorship and friendship.

[115] The Role of Children in the Production of Finger Flutings in Four Upper Paleolithic Caves

The presence of children, through evidence of their hand and footprints, has long been noted in many Upper Paleolithic decorated caves. Previously there was little hard evidence of children as participants in art making. However, recent research focused on forensic studies of finger flutings in four Franco-Cantabrian caves -- El Castillo, Las Chimeneas, Gargas, and Rouffignac -- has yielded evidence of children as active participants in the creation of finger fluted panels. This paper examines the nature of their engagement by examining the places in which children are present and absent, the types of lines they make, their capacity for engaging in symbol-making, their relationships with other members of their groups, and considers questions of why children are present as finger fluters in some Upper Paleolithic caves and not others.

[285] A Comprehensive Analysis of Looted Skeletal Remains from the Site of Panquilma in the Lurin Valley of Peru

Panquilma is a 13th-15th century pre-Hispanic community of the Lurin Valley in Lima, Peru and is located in the hinterland of Pachacamac, an important religious center of the ancient Andes. Sector 03 is composed of hundreds of burial cists, most of which are arranged in clusters and have been heavily looted. Because of this, there is no longer any original context of burial substance. This paper addresses field and lab methodology as well as serves as an examination of osteological and artifact data collected over a period of one month in a superficial cleaning of Unit 14, a burial cist located in Funerary Sector 03 of the Panquilma archaeological site. This area was chosen due to a large concentration of visible artifacts and human remains. The purpose in the superficial cleaning was to recover as much information as possible in a short time frame. Without a superficial cleaning or excavation of an alternate cist for comparison, only speculations can be made as to status of the individuals buried there and their burial rituals. Data collected for this paper specifically targets questions of the number of individuals, demographic composition, social identity, age range, trauma and pathologies of individuals buried there.

[22] Plant Microwear Traces on Flint and Bone Tools from Dutch Wetland Sites: Comparing Late Mesolithic and Neolithic Plant Use

Microscopic analysis of wear traces on flint and bone tools from the Late Mesolithic and Early-Late Neolithic wetland sites in the western part of the present-day Netherlands is revealing valuable information about the use of plants. Obtaining insight into diachronic developments in plant-based craft activities can contribute towards a better understanding of the extended neolithisation process in this area. For example, transversely orientated siliceous plant polish on regular, unretouched blades is known from several Dutch Late Mesolithic wetland sites, but curiously disappears sometime around the Middle Neolithic. Is this due to a change in subsistence and related craft objects? In contrast, bone tools, especially awls, display a strong functional continuity from Late Mesolithic to Late Neolithic: many are used on plant materials. Some of these awls, on the basis of extensive experimentation, can be related to specific products. Other bone tools, like the needles and spatulas which could be associated with netting, basketry and possibly weaving, have not been encountered in Neolithic context so far. These observations will be discussed in the light of experimentation and finds of cordage and textiles to understand developments in wild plant use from Late Mesolithic to Late Neolithic from a tool's perspective.

[110] The Social Life of Houses: Variability in Dynamics of Occupancy on the North and South Coasts of Peru

In this contribution I explore the ways in which construction practices and the dynamics of occupancy (e.g., who dwells where, with whom, for how long?) reveal variability in household composition and post-marital residence practices. The comparison of two distinct but analogous case studies from the Paracas and Moche cultures suggest that such variability may exist in the ancient world and that they are broadly delineated by socio-economic conditions. I argue that architecture and associated archaeological remains reflect different strategies of household social reproduction, intergenerational relations, and group membership. Moreover, similar patterns of dissimilarity are encountered in vastly different cultural, economic, and political contexts. Still, evidence exists in both cases to suggest that this variability in residence patterns may be relatively unstable and short-lived, resulting in more uniform and normative practices. This comparison highlights among other things the diversity in residence patterns that sometimes exists within a single community.

Van Keuren, Scott (University of Vermont) and William Graves (Statistical Research, Inc.)

[159] Cosmology and the Mundane in Hohokam Experiences of Place

Hohokam communities were among the longest-occupied ancient settlements in the American Southwest. Archaeologists have highlighted the links between mountains, caves, and other sacred locations and the placement of “high profile” features such as ball courts, plazas, platform mounds. This paper explores how ritual practices in pits and other “low profile” or mundane features may have played an equally important role in evoking cosmological beliefs, situating communal social relations, and transcribing the potency of specific locations. From an archaeological standpoint, such ritual loci are discrete but nonetheless central to (re)marking historically-charged places in these societies.

Van Peer, Philip

[26] What Is Levallois?

This question has been asked many times throughout the history of lithic studies. Under this heading, I present an analysis of Levallois from a mechanical and technical point of view. Based on such insights, I shall consider the question if Levallois as used in our present systematics represents one and the same approach to lithic production or if it is an umbrella concept which comprises several distinct procedures. Such formal questions are of utmost importance because lithic taxonomy must be taken as the grammar with which historical process has been written.

[44] *Medio Period Ceramic Traditions and the Northern Ramos Zone*

Chihuahuan Polychromes are characteristic of the Medio period, but the ceramic types are not uniformly distributed across the Casas Grandes region. Researchers such as John Carpenter have argued that the different concentrations of ceramic types reflect intraregional social differentiation within the Casas Grandes world. Two of these ceramic zones reflect high levels of Ramos polychrome, a pottery type that appears to be tied to hierarchical leadership and integration with the preeminent site of Paquimé, Chihuahua. The southern Ramos Zone is around Paquimé, and is generally considered the Medio period heartland. The northern Ramos Zone is in the Animas Area of New Mexico. Here, we consider the ceramic and non-ceramic evidence linking the two Ramos Zones, focusing especially on evidence from 76 Draw. We conclude that the two zones reflect close cultural affiliations despite the presence of intermediate ceramic zones that are less integrated with Paquimé and the rest of the Medio period core. We suggest that the northern Ramos Zone acted as a cultural and economic outpost for the Medio period elites to engage other Southwestern peoples.

Van Tilburg, Jo Anne (Cotsen Institute of Archaeology at UCLA)

[211] *Easter Island Statue Quarry: Recent Excavations and New Views on Boundaries, Identity and Resource Stewardship*

Rano Raraku Quarry, Rapa Nui (Easter Island), East Polynesia is the ancient "production center" of monolithic sculpture (moai), a large number of which still remain in situ. Recent excavations, when combined with scientific testing of selected artifacts, geologica! mapping, and image-based three-dimensional technologies, along with ethno-historical documentation and iconographic analyses, suggest the reflexive interactions of socio-political structure and stone resource management c. A.D. 1200-1400. The apparent intent of previously undetected, formalized boundaries was to separate quarries into spatially discrete, identity-linked loci. The Rano Raraku quarry is thus still "inhabited," and the sculpture remain within a luminous landmark one function of which was to provide a sense of place, status, and history.

[103] *Paleopathologies of Site 35 in Salango, Ecuador*

This report describes the findings from a standard osteological analysis of human skeletal remains from three burial vessels unearthed at Site 35 in Salango, Ecuador by the Florida Atlantic University Field School. Based on years of archaeological continuity, it has been established that this site is associated with the Manteno culture, which flourished from A.D. 800 – A.D. 1532, the later part of the Integration Period. A standard analysis of human skeletal remains consists of collecting both metric (measurements) and non-metric (other observations, such as disease and trauma) data, the results of which can later be used to make more detailed conclusions about the daily lives of the individuals. The three urns at Site 35 collectively contain the remains of approximately 700 skeletal elements and fragments, which compose approximately 12 individuals. The observed age range is infant to adult (over 35 years), with remains from numerous juveniles (under 21 years). Several pathologies observed are general indicators of poor nutrition (cribra orbitalia, enamel hypoplasias, and dental caries) and malnourishment (porotic hyperostosis, which is a condition related to anemia and iron deficiency). Additional observations include intentional cranial modification, or binding, a practice of the upper class for religious purposes.

Van West, Carla (SRI Foundation)

[202] *Using Tree-Ring Data to Explore Community Formation in Fourteenth-Century Central New Mexico*

Tijeras Pueblo is 200-room fourteenth-century Ancestral Pueblo settlement on the east side of the Sandia Mountains outside Albuquerque, New Mexico. Although its founders likely came from the Albuquerque Basin, craniometric studies indicate a heterogeneous population. Ceramic analysis supports this and suggests ties to people from the west (Zuni-Acoma region) and south (Rio Abajo region). Using three independent tree-ring chronologies from west-central and central New Mexico and 300 tree-ring cutting dates from Tijeras Pueblo, research indicates the site was not founded or refurbished during periods of local or regional drought and suggests factors other than climate-motivated immigration.

[237] Hot Air Balloons, Looters' Holes, and Pink Flamingos: Teaching the next Generation of Archaeologists with Lessons Learned at WS Ranch

When Jim Neely hired me as a TA at WS Ranch, I had never worked on an archaeological site in the Southwest and I did not plan on becoming a college professor. Two summers working at WS Ranch set me on the path to becoming a teacher of Southwest archaeology, and what I learned in working with Jim remains important to how I teach archaeology today. Jim Neely's contributions as an educator are thus being passed on to future generations of archaeologists. This presentation will discuss how lessons learned at WS Ranch are still relevant in teaching four broad topics within archaeology: Mogollon archaeology, the impact of looting on Southwestern sites, field methods, and life in a field camp.

VanderVeen, James (IU South Bend) and Rebecca Gibson (Fisher College)  
[111] There Is More Than Corn In Indiana: An Examination Of Gendered Artifacts From The Late 19th Century

Where two major roads came into being, and crossed, lives shared an intersection as well. A locally owned pharmacy and a duplex house once stood at the corner of Washington and LaPorte Streets during the early days of the industrial town of South Bend, Indiana. Among the eroded bricks and broken dishes recovered during a recent excavation, many other artifacts of interest came to light. Uncommon, yet simple, objects like a glass doll's eye, a spangle from a belly dancer's belt, and an imported tube of lipstick were examined with a focus towards reconstructing the complex interplay in everyday people's everyday lives. We explore the physical and cultural origins of these objects, as well as what their presence implies about traditional and non-traditional gender roles in Northern Indiana in the late 19th century.

[192] The Dangers of Fishing: The Impacts of Warfare on Subsistence Pursuits in the Mississippian-period Central Illinois Valley

This paper considers how villagers altered their subsistence systems when faced with the intensification of chronic and violent inter-group warfare. Specifically, we address changes in fishing strategies, including shifts in technology (e.g., lines and nets) and preferred location of capture (e.g., river channels, backwater sloughs, etc.), as inferred through species representation, relative abundance, and metric data on fish vertebral centra from five AD 1100-1350 sites in the Central Illinois River Valley. We argue that increasing violence led villagers to decrease the time spent outside of the protected limits of their palisade walls, which would have impacted their foraging activities.

[144] Fashion and Meaning in Medio Period Human Effigies

Casas Grandes Medio period (A.D. 1200-1450) human effigy vessels are unique in the American Southwest and Northern Mexico in that they frequently depict primary and secondary sexual traits, making determination of sex and gender roles possible. We have elsewhere suggested that Medio period symbolism for males and females was influenced by other aspects of Casas Grandes worldview and social life. Gender roles were defined by males' and females' differential association with serpents and birds: males with serpents and females with birds. Furthermore, Casas Grandes cosmology and rituals were based on gender complementarity that combined the productive, reproductive, and ritual activities of men and women within a single system of shamanic ritual practices. Missing from our previous discussions was a consideration of depictions of clothing (e.g., belts and sashes) and personal adornments (e.g., necklaces and bracelets). As with other aspects of Casas Grandes gender roles, there is overlap between what is depicted on males and females (e.g., arm bands), yet women and men appear to be wearing different types of clothes (e.g., women wear string aprons). The role of clothing and
adornment in the development of social identity, gender, and ritual will be examined.

"El Contrato del Mar:" Forced Resettlement and Maritime Subsistence at Carrizales and Conjunto 131, Zaña Valley, Peru

In this presentation, we analyze the effects of Spanish colonial forced resettlement (reducción) on maritime subsistence in the Zaña Valley, on Peru’s north coast. While our archaeological survey reveals substantial continuity in maritime settlement in the Zaña Valley between the 6th and 17th centuries CE, our excavations of households and middens at two sites (a reducción settlement named Carrizales and an adjacent prehispanic fishing village, Conjunto 131) outline marked shifts in species presence and diversity before and after forced resettlement (ca. 1572 CE). We examine several hypotheses that might account for these differences, including demographic decline, environmental change, and increased tribute demands placed on indigenous communities by the Spanish administration. In the context of this symposium, our presentation serves to underscore the dynamism of coastal Peruvian lifeways under changing political-economic conditions and provides a crucial link between ethnohistoric and archaeological scholarship on late prehispanic and early colonial coastal communities in Peru.

The Introduction of Agriculture and the Beginning of Pueblo Indian Settlement in the VEP North and South Study Areas

The Village Ecodynamics Project (VEP) examines the long-term interaction between Pueblo Indian people and their environment, linking the distant ancestral Pueblo past to the formation of historic-period Pueblo towns. This is accomplished by modeling Pueblo settlement between A.D. 600 and 1760 in two study areas: one in the Mesa Verde region of southwestern Colorado and the other in a portion of the northern Rio Grande drainage of New Mexico. As an archaeological culture, Pueblo Indian society first becomes visible with the introduction of agriculture and the shift from a subsistence economy based on hunting wild animals and gathering wild plants to an economy based on domesticated food production. This paper examines the introduction of agriculture in the two areas examined by the VEP in order to better understand the initial period of settlement period in each area. Although general similarities characterized the adoption of agriculture in the two study areas, the specific processes that led to the initial period of settlement by large numbers of Pueblo farmers appear to be quite distinct.

An Overview of Investigations at Sierra Diablo Cave, Texas (2008-2013)

Excavations at Sierra Diablo Cave, located in Trans-Pecos, Texas, have continued every year since 2008. The site is a now-dry, stratified cave and exhibits excellent overall preservation of cultural and faunal materials. In addition to documenting a well-expressed Archaic occupation, the project has focused on in situ Pleistocene deposits which contain late Pleistocene vertebrate fauna [e.g., (Equus (horse), Capromeryx (miniature pronghorn), Stockceros (Stock’s pronghorn), Nothrotheriops (Shasta ground sloth), Desmodus stocki (Stock’s vampire bat), Aztlanolagus agilis (Aztlán rabbit), Coragyps occidentalis (Western Black Vulture), Gymnogyps californianus (California Condor), and Panthera atrox (American lion)), stone and bone tools, and charcoal. Archaic items recovered from the cave (during and prior to the last five years of documented work) include atlatls, projectile points, sandals, basket fragments, corn cobs, and various other textiles. Lower deposits, associated with Pleistocene fauna, include stone tools, a bone point, debitage, and various other items. Biogenic, geogenic, and
anthropogenic processes influenced the current state of stratigraphic continuity and composition throughout the site. The older sediments include eolian fines, abundant mammal dung, some roof fall, and water-lain deposits, probably from former seeps in the cave.

Vasquez, Augusto (PUCP)

The objective of this presentation is to compare the status between the inhabitants of the two groups of household compounds, the central and peripheral, in Panquilma's domestic sector.

The central household compounds are adjacent to the pyramids and people who lived there could be involved in the activities of the public sector. The occupants would have had a higher status, and archaeological materials should reflect this social dynamic. In contrast, the peripheral compounds were built later and are located more distant from the public sector; these occupants should not have the same status. Through the analysis of ceramics, I will identify the variety in the types to recognize domestic activities that may be developed in the household compounds. In addition, the quality and quantity of ceramics suggest differences in accessibility when contrasting the households compounds. I will focus on two patios characterized by continuous use located within the domestic area of Panquilma.

[295] Geospatial Data and Dialog: Perspectives from an Interdisciplinary Project Along Quintana Roo's North Coast

Members of the Proyecto Costa Escondida have been conducting interdisciplinary investigations along the northern coast of the Yucatan Peninsula since 2006. Our team consists of archaeologists, a coastal ecologist, a hydrogeochemist, and a geoarchaeologist. In attempting to understand coastal adaptive strategies over the past 3000 years, project members have collected and used many datasets – from sediment cores and traditional archaeological materials to various remotely sensed platforms. This paper focuses on the challenges encountered when trying to integrate these remotely sensed datasets – LiDAR, and SRTM elevation data; ASTER, GeoEye, IKONOS, Landsat VII and Landsat 8 multi-spectral satellite imagery and aerial photos from INEGI – into our investigations of the complex coastal geography. We examine the development of project specific data standards to facilitate dialogue in an interdisciplinary setting while also navigating the needs of other project stakeholders including local communities, national governments and federal funding agencies.

[27] Plazas and Pilgrimage in the Upper Ica Valley

Documented plaza use in the Southern Nasca Region (SNR) has demonstrated that communal plazas were absent at residential sites during the Early Nasca period. Indeed, communal rituals and performance were limited to the pilgrimage center of Cahuachi and associated features of the built environment such as the Nasca geoglyphs. Building on this previous work in the SNR, in this paper we report on evidence for the use of plazas and related communal spaces in the Upper Ica Valley during the first few centuries of the Early Intermediate Period (EIP). Specifically, we report on two sites in the Upper Ica Valley with early EIP components: Cerro Soldado and Cerro Tortolita. While Cerro Soldado lacks plazas and communal architecture, the built environment at Cerro Tortolita features platform mounds and several associated communal plazas. Using architectural and ceramic evidence, we suggest that the differences are attributable to Cerro Soldado’s engagement with the Cahuachi pilgrimage system in the SNR, while residents of Cerro Tortolita focused locally on community ritual.

[77] Does Archeological Site Monitoring Work? The National Park Service’s Midwest Region’s Ranger Monitoring Program

The Midwest Region of the National Park Service developed a program that uses park protection officers to monitor archeological sites on an annual basis. The program just completed its fifth year of operation.
and has provided archeologists with an immense amount of data about the threats to, and state of preservation of, the park’s archeological resources. But, does the program work? Has the effort resulted in better protection of archeological sites or has it simply been an exercise in bureaucratic paperwork? Data collected over the last five years is compared to data about the sites prior to the program to analyze the value of the program. Benefits include improved documentation and knowledge about the sites, better communication between park staff and regional archeologists, and buy in from park rangers that resulted in an increased interest in protecting the resources in their parks. Additionally, threats that have been identified by rangers have been addressed to limit future damage. Both add up to better protection for the regions important sites.

Vázquez, Ricardo (Museo Nacional de Costa Rica) and Robert Rosenswig (University at Albany) [197] The Las Mercedes site: The Emergence of an Important Sociopolitical Center on the Central Caribbean Watershed of Costa Rica
This paper presents new architectural data and radiocarbon dating gathered from Las Mercedes in 2009 and 2012. Las Mercedes was recognized as an important center during the 19th-century, before any other complex site of Lower Central America. New investigations begun in 2004 provide evidence of the site's layout and chronology indicating that an intensive building project started at the onset of Period VI (900-1550 CE). During this period, Las Mercedes was a gathering hub with formal accesses along two expansive causeways (each longer than 1 km) that meet at a system of monumental architecture that include a 6 m high central mound and a reflecting pool. Period VI construction consists of earthen fill faced with river cobble transported from nearby waterways. Construction of this Period VI architecture incorporated Formative-period remains as well as denser deposits from Period V (300-900 CE) occupation of the area. We propose that a population rise before 900 CE and geo-environmental factors played a role on the emergence and placement of Las Mercedes as a regional center.

Vazquez De Agredos Pascual, Maria Luisa (Departamento de Historia del Arte, Universidad de Valencia), Cristina Vidal Lorenzo (Departamento de Historia del Arte, Universidad de ), Patricia Horcajada Campos (Departamento de Historia del Arte, Universidad de ), Vera Tiesler (Facultad de Ciencias Antropológicas, Universidad A) and Patricia Quintana Owen (CINVESTAV, Mérida, México ) [164] Body Paint and Rites of Passage in Maya Culture
The ancient Maya considered physical death as a rite of passage to another state. This explains the high symbolic value of many of the elements forming parts of the funeral ceremonies of royalty in which the deceased was prepared with the purpose of aiding this sacred passage. From very ancient times, one of these elements was that of color, particularly red, though this was not the only color, whether introduced as part of the burial offerings inside different types of vessels, to cover the funeral bundle, or even to shroud the corpse. Recent archaeometric results gathered at University of Valencia and Polytechnic University of Valencia suggest that many of the pigments used were perfumed ointments with cosmetic properties. What were the raw materials used in the preparation of these intensely scented body paints used in Maya death rituals? In what way did the color and the aromatic excipient combine in highly technical recipes with profound symbolism destined to be spread over the corpse and head of the deceased king? This paper aims to tackle these and other questions on the basis of an interdisciplinary study combining the different fields of history of art, history and the chemical analysis.

Vehik, Susan (University of Oklahoma) [220] Mother Moon, Father Sun and the Little River Focus Council Circles of Central Kansas
The council circles are unique structures on the Plains. They are comprised of four semi-subterranean structures organized to form a circle. Over the years many different explanations have been created for the circles. Some of these are quite fanciful, including Celtic Israelite temples. Most often though they are suggested to be religious centers, residences of elites who dabbled in religion, forts, men’s lodges, and solstice monitors. Their symbolic significance, however, has never been investigated. A survey of
Caddoan ethnography provided possible symbolic meanings for council circle shape and for each of the structures comprising the council circle. From this, material manifestations of potential symbolic meanings were defined and investigated. The council circle shape may represent the cross and circle motif of a tripartite world, while the structures appear to be associated with both medicine and warrior aspects of the sun and moon.

Cemetry Reform In 19th-Century Puerto Rico: Enlightenment Principles in a Colonial Setting  
Puerto Rico’s 19th century cemeteries are incredible repositories of mortuary art. Resembling the famous cemeteries of New Orleans, Louisiana, they contain a wide array of family monuments and finely executed marble statuary. They are cultural and historical treasures. However, they have seen only limited attention from scholars. Most are organized on a cadastral grid, are walled, have gatehouses, family tombs or panteons, niches for individual burials, autopsy buildings, and ornamental statuary. They were built outside of and downwind of the communities they served. The markers in the cemeteries were produced locally, or were imported from Spain, Italy, or South America. In their designs, they reflect Enlightenment ideas common in late 18th century Europe. Interpreted and codified by the Bourbon rulers of Spain, these new “rational” ideas about how cemeteries should be designed were imposed on the colonies. They provide an important alternative to the romantic Rural Cemetery Movement seen in North America which inspired by northern European cemeteries such as Pere Lachaise in Paris. Rationally designed, they placed an emphasis organization and hygiene, highlighted the family rather than the individual, and remain important sites of commemoration and community pride today.

Velasco, Matthew (Vanderbilt University) [150]  
Biosocial Affinity and Differentiation at a late Prehispanic Chullpa Cemetery (Colca Valley, Peru)  
During the Late Intermediate Period (AD 1000-1450), novel mortuary traditions involving entombment in above-ground funerary structures (chullpas) proliferated across the south-central Andes. Chullpas are most commonly interpreted as monuments to the social and territorial integrity of competing kin groups, or ayllus. These interpretations, linking ayllu, territory, and open sepulchers invoke classic structural-functional hypotheses, in which formal burial or tomb building serves to legitimize resource rights of segmentary social groups, especially in the context of population stress and resource competition. Well-preserved human remains from the cemetery site of Yuraq Qaqa in the Colca valley (Peru) provide a rich body of evidence to examine the applicability of these approaches to above-ground mortuary traditions during the late Prehispanic period. In this paper I explore the relationship between chullpa construction, boundary maintenance, and lived experience in the ancient Colca valley using preliminary data on biological affinity, cranial vault modification, and skeletal morbidity. Rather than approach Late Intermediate Period chullpas as a singular material phenomenon, this study suggests that the degree to which chullpa monuments promoted social exclusion or integration may vary by region and cultural context.

Lithic Technological Trends of Clovis and the Older-than-Clovis Components at the Gault Site, Bell County, Texas (41BL323)  
As one of the largest multi-component archaeological sites in North America, the Gault site (41BL323), located in central Texas, provides a unique opportunity for researchers to analyze changes in technological traits and attributes both spatially and temporally from a workshop setting as well as an inter- and intra-cultural perspective. Controlled excavations at the Gault site since 1999 have recovered flaked stone tools, along with debitage and faunal remains in situ from Clovis and well below the known Clovis horizon. These older deposits are ~ 80 cm deep and are referred to as the Older-Than-Clovis (OTC) horizon. This poster will present a macroscopic analysis of these artifacts focusing on the technological trends and attributes of the OTC flaked stone tool assemblage compared to the Clovis age assemblages through diagnostic and individual flake analysis. These trends and attributes will provide sought after insights into the technology and reduction sequence of the OTC flaked stone tool
component. This poster will also demonstrate the on-going investigations and provide brief discussions outlining the results from the analysis of the OTC assemblage as well as providing the similarities and differences as compared to Clovis industries.

[128] Late Classic Boundary Interactions in the Southern Gulf Lowlands
Borders and frontiers constitute poles on a continuum of cultural boundedness, the former as closed, rigid demarcations, the latter as permeable, fluid zones of interaction. The establishment and maintenance of either kind of boundary proceeds through definition of difference and negotiation of position, both internally and externally. These principles are well illustrated in the Classic and Postclassic archaeology of the Gulf lowlands in southern Veracruz and western Tabasco. Bounded by a fluctuating ethnolinguistic divide between Maya to the east and Mixe-Zoqueans to the west, the southern Gulf lowlands nurtured precocious sociopolitical complexity and distinctive stylistic and arquitectonic expressions; exported widely distributed fine-paste ceramics, and served as a conduit for exogenous materials, styles, and ideological complexes. We explore frontier interactions and internal boundary negotiations during the Late Classic period (A.D. 600-900), when the southern Gulf lowlands experienced peak population levels and the proliferation of a multitude of modest centers. Distributional patterns of ceramic complexes and civic-ceremonial layouts suggest maintenance of relatively open political boundaries internally, while participation in a Gulf Coast-Maya tradition of hollow mold-made figurines, export of local ceramics, and transshipment of Mexican obsidian to Maya centers underscore the multidimensional character of frontier interactions.

[238] Los Sistemas Constructivos del Conjunto Monumental de Atzompa
A lo largo de las excavaciones de los edificios monumentales, las unidades habitacionales y los diferentes espacios bajo la investigación arqueológica, se han encontrado variados sistemas constructivos que cumplen propósitos diferentes. Esta diferenciación constructiva es muestra del entendimiento de los materiales usados para la construcción así como del entorno sobre el cual este conjunto monumental fue construido que va ligado con las variadas funciones que los espacios del Conjunto Monumental tuvo para cada caso. Esta exposición es sólo una muestra de esas variaciones de uso de los espacios apoyados con los sistemas constructivos y como el entendimiento de su entorno les permitió generar un satisfactor a algun tipo de demanda social.

Verano, John (Tulane University)

Isolated human skulls and headless bodies appear sporadically in the archaeological record throughout the world. These discoveries frequently provoke debates about the context and cultural meaning(s) of practices leading to the intentional separation of head and body. While archaeological context suggest that headless bodies frequently receive only limited attention (abandonment or prompt burial), disembodied heads often experience a more complex “afterlife”—one that may involve treatment to preserve the facial features and hair, or modifications of the skull such as defleshing, perforation, sectioning of the cranium, surface decoration, and the attachment of suspensory cords. These elaborate treatments of the head underline its symbolic importance, whether it represents a specific individual or a member of a particular social group. Disembodied heads (mummified and skeletonized), are known from many Prehispanic cultures of Peru. Determining the origins, method of preparation, and possible ritual/political function of these heads continues to be a challenge for archaeologists and biological anthropologists—one that clearly requires a multidisciplinary approach.

Verdugo, Cristina (California State University, Los Angeles), Toni Gonzalez (California State University, Los Angeles) and Helen Haines (Trent University)

[70] An Analysis of Skeletal Material from Chultuns C-1 and B-2 at Ka’Kabish, Belize: A Reconsideration of the Mortuary Function of Chultuns
Excavation of Chultuns C-1 and B-2 by the Ka’Kabish Archaeology Research Project during the 2012 and 2013 field seasons has yielded the remains of at least five individuals. Although the context of Chultun C-1 was heavily disturbed, the context in Chultun B-2 demonstrates that the chamber had been used for deliberate interments. The mortuary function of chultuns has long been recognized in the southern Maya lowlands by such early investigators as Tozzer, Gann and Ricketson but the use is described as
“occasional” and “secondary”. Puleston’s 1971 analysis is seriously flawed by his assumption that the concentrations of chultuns in residential areas suggested a secular rather than ceremonial function. He also cites the “occasional” occurrence of burials to eliminate the mortuary use as a primary function and this allows him to dismiss the burial data from speaking to the wider issue of chultun function. It is obvious that mortuary ritual was being carried out in a subterranean space. The presence of multiple individuals suggests the repeated performance of rituals which constitutes a process of sacrilization of that space. Even as a secondary function the implications of this activity cannot be ignored in a discussion of a feature’s function.

[316]  Defending Ethnographic Analogy
This project addresses theoretical and methodological issues surrounding the use of ethnographic analogy. The immediate aim is to clarify and expound on the various forms ethnographic analogy may take, the specific problems facing each, and proposed solutions. Part of the project aims at drawing out useful comparisons and contrasts between the theoretical and methodological debates concerning the reliability of ethnographic analogy in archaeology and epistemological debates in the philosophy of science over the nature of empirical observation. The ultimate goal is to defend ethnographic analogy as a reliable mode of inference for reconstructing human behavior in the past.

Verostick, Kirsten (UTSA-CAR)

[199]  Fine-grain Diet Reconstructed from Stable Carbon and Nitrogen Isotopes in Prehistoric Hair: A Case Study from the Lower Pecos Region in South Texas
Stable isotope research has experienced refinements in analytical techniques and interpretations allowing complex reconstructions of prehistoric diets at variable temporal scales. This paper presents a fine-grained analysis of hunter-gatherer diet in the Lower Pecos region using stable carbon and nitrogen isotopic data extracted from human hair. Isotopic analysis of hair from a desiccated Late Archaic (ca. 1200 cal B.P.) individual recovered in the 1930s from a shelter illustrates a monthly diet reconstruction. Critical to this reconstruction is the establishment of the early summer as an approximate season of death for this individual, called the Skiles Mummy. This early summer period is inferred based on previous analysis of intestinal contents. Assuming a rate of hair growth at roughly 1 cm a month, the approximate period of death allows a monthly determination of stable carbon and nitrogen isotopic values in hair segments for roughly the last 1.5 years of life for this individual. These data show dramatic seasonal shifts over a single year, with a 2.9‰ difference in δ13C values and a 1‰ difference in δ15N values. When combined with ecological data on resource availability, the results of this fine-grained reconstruction allow us to address questions about seasonal resource use in the region.

[156]  Dating Kimberley Rock Art: the long and the short of it

Versaggi, Nina (Binghamton University (SUNY))

[304]  Beyond the Artifact: Teaching Consultation within the Academy and CRM
An important goal in the training and mentoring of the next generation of CRM professionals is the production of competent participants in the complex process of consultation with descendant communities and others. In my dual role at Binghamton University as director of the Public Archaeology Facility (PAF) and as a faculty member, I have many opportunities to mentor young archaeologists, both staff members and graduate students. I stress the importance of looking beyond the artifact to the heritage embodied in the material item. The same is true for the practice of CRM. Looking beyond the checklist to the constituents, stakeholders, and advocates (which also includes project engineers and sponsors), and conducting open dialogues ensures the success of a project from multiple perspectives. I co-teach a graduate level course on Heritage Resource Management and Practice at Binghamton University. The class balances instruction with case studies drawn from work in CRM and other heritage projects. In this paper, I will discuss the concept of consultation, and illustrate the use of case studies in educating the next generation. The PAF case studies I will use include the historic Gilboa Dam reconstruction project, and two Binghamton downtown projects rich in Native American heritage.
The rock art corpus of the Kimberley region of NW Australia is famous for the diversity of art schema culminating in the Wandjina repertoire dating to the last 4,000 years. While terminal Pleistocene dates have been obtained for Gwion (Bradshaw) motifs the question of how old the earliest figurative pigment art is remains open. With an increasing number of occupation sites now dated in the Kimberley to circa 50,000 BP it can be reasonably posited - was art part of the colonising repertoire? This paper reviews the current evidence and looks at the theoretical basis for an earlier body dating back to before the Last Glacial Maximum.

Determining the Effects of Bioturbation on Prehistoric Great Basin Sites

Previous studies have indicated that surface artifact diversity is typically not representative of overall site assemblages at many prehistoric sites in the Great Basin. This study investigates in more detail the effects of bioturbation on the post-depositional mobility of lithic artifacts at 20 excavated prehistoric sites located in eastern Nevada. This analysis focuses on identifying modal patterning in subsurface debitage distributions consistent with the formation of stone zones, accumulations of large clasts that collect immediately below the zone of maximum rodent disturbance. Results indicate that excavated lithic assemblages exhibited distinct vertical patterning with respect to cultural and natural depositional processes. Units in which artifact frequencies peaked at 30-50 cmbs also had corresponding peaks in natural inclusions, suggesting artifacts in these areas had been significantly displaced post-burial. The prevalence of stone zones appears to vary on the intra-site scale, suggesting bioturbation intensity is a factor of variability in sedimentary texture, vegetation growth, and soil compaction. These findings reveal that many Great Basin sites may actually contain large subsurface components as a result of post-depositional downward displacement of artifacts, even in actively erosional or stable geomorphic environments.

Vicente Cruz, Ismael Gabriel [83] see Whittington, Stephen

Vidal, Cinthya (Centro INAH Sinaloa)

The implementation of earth science techniques has helped us to know the origin of Aztatlán pottery from the Mexican states of Durango and Sinaloa. The results of this work suggest that these objects were produced on both sides of the Sierra Madre Occidental, on the coast and in the highlands. This has certainly changed the way we understand the Chalchihuites-Aztatlán interaction. Not only does a microscopical study of pottery help us to know its origin, but it also provides us with some evidence about ceramic manufacture. By contextualizing our results with other archaeological, ethnohistorical, and ethnographical data, we can obtain some evidence about the cosmology of the ancient inhabitants of northwestern México. Using thin section analysis as a base, in this paper I suggest an interpretation of the method and techniques employed in the Aztatlán chaine opéraire. In addition, I propose that the inhabitants of the Guadiana Valley in Durango, and those in southern Sinaloa and northern Nayarit, shared a set of cosmological beliefs based on the observation of the path of the sun.

[19] Pottery and Social Complexity in Tarapacá, Atacama Desert (Northern Chile)

Based on multiple studies, it has been suggested that the earliest pottery producing communities in Tarapacá (Northern Chile) appeared c. 900 BC, in conjunction with a process of exploration, settlement, and exploitation of resources that intensified between 200 and 900 AD. In this scenario, agricultural and ceramic innovations, among others, were developed in an environmental setting that is at present extremely arid, associated with local coastal populations and with independence from external agents. Thus, this region of the South Central Andes developed its own social complexity, which was affected by other populations only during later periods. In the present study, this particular situation is exemplified through our investigation of regional ceramics using petrography, thermoluminescence, and neutron activation analysis (NAA), as well as chronological and stylistic approaches (FONDECYT 1080458 y 1130279).

Vierra, Bradley (Statistical Research Inc)

[294] Land Use and Social History in the Southern Chuska Valley

Movement has always been a critical part of life for the prehistoric people residing in the Southwest. This movement involves periods of relative residential stability with some households emphasizing a greater degree of mobility and others aggregating into communities with more complex occupational histories. Therefore the discussion has shifted to cyclic patterns of regional movement that provide for a much larger scale of residential mobility than previously imagined. Both foragers and agriculturalists traveled over great expanses of the landscape during their lifetimes and across successive generations. The knowledge of this history would have become an integral part of their lives and cultural identity.

[293] La construcción de arqueologías transnacionales en el Noroeste/Suroeste

Durante la última década hemos intentado llevar a cabo en el Noroeste de México la construcción de arqueologías transnacionales debido al hecho de que nos enfrentamos con una realidad bastante diferente a la de los arqueólogos mesoamericanos. La existencia de una frontera internacional que divide un espacio que estuvo integrado en el pasado, comunidades indígenas separadas por esa misma frontera y una legislación federal para México que enfatiza la condición de monumento de los vestigios arqueológicos, nos han llevado a plantearnos una visión amplia de los procesos históricos y culturales que han existido en este espacio que llamamos Noroeste/Suroeste y que no debería estar artificialmente limitado por fronteras políticas, culturales o lingüísticas. Nos encontramos en la construcción de arqueologías transnacionales que deberán ser arqueologías de emplazamientos múltiples, no obstante que los investigadores trabajen en diferentes “naciones”, siempre y cuando se encuentren comprometidos con la necesidad de re-examinar las contribuciones que la disciplina puede aportar a la sociedad y expandir la arqueología del Noroeste/Suroeste tanto lingüística, como cultural y regionalmente.

[65] OpenDig: Digital Field Archaeology, Curation, Publication and Dissemination

OpenDig is a platform for recording, editing, managing, and publishing archaeological data. It comprises three related applications, one for data entry in the field using hand-held mobile devices, another as a light-weight utility to view and edit data during an expedition, and finally a full web application with complete tools for research and analysis. The OpenDig framework relies on open source tools that allow for easy data sharing using standard web-based protocols. This allows for new tools to built on the existing application programming interface (API) for extendibility and collaboration. Through CouchDB, Apache’s NoSQL database, OpenDig is able to adopt a flexible data structure which can be easily modified to fit any particular project, whether it is excavation, survey, or other cultural heritage management systems. The three tiered approach also allows for deployment in areas where there is little or no Internet connectivity, allowing for any laptop to act as a portable server for the database and each device acting as a redundant copy for maximum data protection.

Vincent, Monique (University of Chicago)

[127] Last Moments at ‘Umayri: Daily Life in Early Iron Age Transjordan

Tall al-‘Umayri is a multi-period site located in the central highlands of modern Jordan. The Early Iron Age (ca. 1200 BCE) settlement at ‘Umayri was a small, agro-pastoral village that was short-lived, destroyed in a massive conflagration less than a century after its construction. The fire and resulting collapse sealed in the last moments of the inhabitants, preserving artifacts scattered on the floors and in the tumble of five domestic structures. These artifacts, excavated by the Madaba Plains Project over the past twenty years, represent everyday activities related to food preparation and consumption, and the production of lithics, textiles, and seals. These daily activities integrated locally produced artifacts as well as regional ceramics, basalt tools, and Egyptian imports. This paper explores how these various artifacts lend insight into the activities of these households during their final days. The larger context of my research is understanding the social identity of the small, highland villages located on the fringes of the collapsing Egyptian empire. I argue that understanding social identity as practiced every day at the household and community levels at ‘Umayri contributes to a better understanding of the diversity of social expression in the Early Iron Age.

[138] 3D Digital Reconstruction of Salt Production Ceramics Used by the Maya in Paynes Creek National Park, Belize

The 3D digital reconstruction of Maya pottery vessels provides valuable insights for study, teaching, and exhibits. We made 3D scans of pottery rim sherds using a Next Engine scanner. The rim sherd 3D images were imported into Rhinoceros 4.0 NURBS modeling software where we reconstructed complete digital pottery vessels. We also used profile drawings of rim sherds drawn to scale in Rhino software to make complete digital vessels. Our case study is the Paynes Creek Maya Salt Works, where brine was evaporated in pots over fires to make salt. Digitally reconstructing complete pots from sherds helps calculate vessel volume and hence estimates of salt produced. The digital vessels provide a permanent record for research, teaching, sharing, and for 3D printing.

[34] Agent-Based Geo-Spatial Approaches to Understanding Prehispanic Pastoralist Ecology in the South-Central Peruvian Andes

One of the challenges for a settlement ecology approach in archaeology is parsing the influences of environmental, cultural, and human behavioral/biological factors on settlement distributions. Spatially-contingent agent-based modeling (S-ABM) provides one fruitful avenue for understanding these relationships. I apply S-ABM to late prehispanic settlement shifts among high-elevation sedentary pastoralists in the Suches basin of southern Peru. Parameters include household demographic and nutritive requirements; herding reproductive and stocking dynamics; and fluctuating environmental conditions. Different scenarios evaluate the relative importance of subsistence-, optimizing-, and maximizing-strategies within various socio-cultural and physical environments. Results suggest shifts in settlement criteria from strategies that were principally environmentally-sensitive to strategies that increasingly prioritized socio-cultural considerations such as production for non-local consumers and ties to transportation routes. These shifts coincide with increasing anthropogenic intervention in natural ecological systems, and human niche construction through the legacy of land use impacts. S-ABM helps
to differentiate important transitions in socio-ecological relations, and it helps to identify human behavioral tipping points that have led to the creation of anthropogenic settlement-ecological systems.

[150] Redefining the Late Intermediate Period on the North Coast
As more research is conducted and the catalog of absolute dates increases, the traditional Andean chronological framework based on alternating periods of political unity and fragmentation continues to lose practical relevance. This is certainly true for Peru’s north coast, where recent fieldwork has taken a more nuanced approach to characterizing sociopolitical organization and dramatically changed our understanding of the events that took place during the Middle Horizon and Late Intermediate Period. Specifically, investigations at several sites have clarified the lesser, more indirect role of the Wari Empire, the later dates and diverse strategies of Chimú imperial expansion, and the previously ignored but significant presence of the Casma polity. Using evidence from the Casma capital city of El Purgatorio, this paper examines Casma influence on coastal cultural development during the Late Intermediate Period and the implications for reinterpreting the regional culture history. The data suggest that while the Middle Horizon witnessed myriad changes in coastal political structure and religious practice, much of the Late Intermediate Period appears to have been dominated by three large coastal polities (the Casma, Chimú and Lambayeque) that participated in interregional exchange and coexisted peacefully for centuries.

[32] Pithouse Period Shell Games: The Shell Assemblage from the Harris Site
The presence of extensive trade networks, which linked the Mimbres region of southwestern New Mexico with the Hohokam and other cultural groups to the west and south—ultimately extending to the coastal regions of the Sea of Cortez and California—has long been recognized. The structure and nature of the network during the Pithouse period is explored through the lens of recently excavated shell materials from the Harris site, which is augmented through a re-evaluation of the legacy collections from the 1930’s excavations by Gila Pueblo.

[132] Forward to a New Biological Paradigm in Human Behavioral Ecology: The Potential of Epigenetics on Archaeological Theory & Practice
Over the course of the last two decades, researchers working on the frontier of biological inquiry have been forced to reconsider our fundamental understanding of evolutionary mechanisms, through the lens of "epigenetics"—defined as the study of bio-chemical phenomena that lead to functionally relevant changes in behavior and gene function. Epigenetic changes generally occur "outside" the function of the genome, proper; often as a direct result of environmental interaction. More importantly, such changes mostly take place without altering the underlying DNA sequences; but nonetheless, appear to be transmittable, even from one generation to another. This presentation seeks to explore the more profound implications related to the adoption of an epigenetic biological paradigm to frame the study of Human Behavioral Ecology—specifically, as it relates to archaeological theory and method. For example, studies indicate that even slight changes to the proteome (not completely genomic, in origin) can produce profound changes in behavior and phenotypic expression. An emergent ability to identify species-specific protein molecules in archaeological context, may soon allow researchers to better quantify theories that purport to explain the degree to which ecological factors affect human diversity, behavior, and culture.

[128] Entwined Communities and Enmeshed Polities: La Venta and the Middle Formative Greater Tabasco Plain Region
Middle Formative La Venta, Tabasco is a paramount representative of the Mesoamerica-wide movement
toward urbanization well underway by the middle centuries of the first millennium before the Common Era. It is also something of a misplaced city, offset from extensive regions of prime maize and yucca growing soils. We combine multi-mode and multi-scale (spatial) landscape and settlement analysis of the Tabasco Coastal Plain, Plan Chontalpa, and La Venta polity using high resolution satellite and region-wide LIDAR data with recent and historical archaeological data to explore networks of interaction linking La Venta with communities and polities across the coastal plain and into the adjacent Southern Veracruz, Chiapas, and Maya regions at various spatial scales. This study integrates a developing, region-wide unified artifacts database with formal settlement and landscape-based network analysis. The heterogeneity of data require multiple approaches, thus we test various approaches to formalizing spatial-governed measures of interaction. We incorporate a Bayesian analysis of recent, unpublished radiocarbon dates from the La Venta polity and adjoining Plan Chontalpa region to fine tune chronologies of interaction.

Von Schwerin, Jennifer (German Archaeological Institute) [154] The MayaArch3D Project: An Open Source 3DWebGIS for Archaeological Research
The MayaArch3D Project is an interdisciplinary, international project that is developing an open source research tool, a 3DWebGIS, that will allow scholars to combine 3D-Models (from laser scanning, photogrammetry, or CAD programs) with the functions of GIS in order to document and analyze archaeological sites in a single internet platform. Using this tool researchers can visualize, search and query, in real time, segmented 3D models of multiple resolutions that are integrated in a Geodatainfrastructure (GDI), linked to attribute data stored in a spatial database. This enables online, 3D analysis of maps of settlements, their access and visibility, topography, architectural and landscape alignments, and spatio-temporal distribution of features. Information and objects that are housed in disparate collections around the world can be documented, geo-referenced, virtually combined and analyzed on this one platform according to international data sharing and data security standards. The test data in the tool is from the ancient Maya kingdom and UNESCO cultural heritage site of Copan, Honduras. The tool is a prototype that can be adapted for use at other complex archaeological sites worldwide. Beta tests indicate the potential of this tool to assist collaborative research and to develop new analytical methods in the humanities and social-sciences. [154] Chair

Voorhies, Barbara (University of California, Santa Barbara) [277] A Ritual Location at the Rear of The Entrance Chamber of the Las Cuevas Cave
Project members placed a lateral excavation (Cave Unit 3) that spanned the width of the passageway (8 x 5 m) at the rear of the Las Cuevas Entrance Chamber, just in front of an ancient Maya wall restricting access into the deeper recesses of the cave. Removal of an overburden of water lain silt revealed two low plaster encased platforms resting on a plaster floor that extends across the width of the passageway. Many small objects, in addition to copious potsherds and dense charcoal fragments are scattered on this floor, especially in front of one platform that contains abundant freshwater snail shells (jutes) within its construction fill. We think that these objects are in primary context where they were placed as offerings, and that deep cylindrical holes chipped into the floor in various places appear to be offering holes. Two associated fire features document habitual burning at this location. The incorporation of highly symbolic jute shells within the focal platform may hold a clue regarding the nature of the former ritual.

Vranich, Alexei (Cotsen Institute) [27] Plazas in the High Andes
Primary ritual and public spaces at Tiwanaku held sacred idols, and while they were the controlled setting for choreographic interactions with high status and important residents, these spaces were both conceptually and experientially very different from plazas in the modern, developed world. Tiwanaku plazas or courtyards had panoptical qualities, but rather than placing local residents or visitors under
scrutiny, they fixed the surrounding landscape under its gaze. This spatial and visual effect was fashioned by dropping the floor deeply into the ground until the surrounding ground surface fell from view. Pillars and gateways around the boundaries of the plaza created visual points of reference to frame landscape features and astronomical bodies, and they contributed to sacred landscape narratives by changing visual relationships between the earth and sky.

Waber, Nicholas (UBC) [160] Customizing Microblades: A Design-Theory Analysis of Microblade Production and Alteration Practices on Early Holocene Haida Gwaii

This paper examines an early Holocene microblade assemblage from Haida Gwaii, British Columbia, in order to assess how the microblades were hafted, and thus used. The Richardson Island site in southern Haida Gwaii yielded a substantial microblade assemblage and tremendously fine-grained stratigraphy, allowing a unique view into the earliest adoption of microblade technology in the area. Following the principles of design theory, the microblade assemblage was analyzed in order to identify morphological patterns that would provide indications of how the microblades were implemented in a composite tool setting, and how they were integrated within the broader toolkit. The findings suggest that microblades were used as side-hafted insets in slotted point hunting weapons, and that a regimen of deliberate microblade alteration was employed in order to fit each bladelet to its setting. This paper will discuss this alteration practice, what makes an ideal Haida Gwaii microblade, and how to “find” slotted points without finding a slotted point.

Waddington, Clive [17] Paradise lost, Paradise Regained: Mesolithic Resettlement of the North-East British Coast after a Catastrophic North Sea Tsunami

The Northumberland coastline on the north-eastern seaboard of the British Isles contains a well-preserved sequence of Holocene sedimentary and archaeological deposits that are currently being eroded as a result of rising sea levels. Recent investigation of an extraordinary sequence of archaeological remains interbedded with catastrophic inundation deposits has yielded evidence of early and mid-Holocene hunter-gatherer occupation interrupted by a tsunami event thought to be the '8.2 event', followed by a return of hunter-gatherer settlement. The impact of this tsunami on the geography of the North Sea is briefly discussed together with the substantial lithic assemblage, carbonized plant remains and settlement structures that document the post-tsunami use of this landscape by subsequent generations of hunter-gatherer-fisher groups. This unusually preserved site provides an insight into dynamic landscape change through the Holocene, and one in which humans eventually returned after a catastrophic environmental event - a case of paradise lost and paradise regained.

Wagner, Ursel (TU-Muenchen), Rupert Gebhard (Archaeological State Museum, Munich), Zsolt Revay (FRM-II, Technical University of Munich ), Peter Albert (Archaeological State Museum, Munich) and Friedrich E. Wagner (Physics Department, Technical University of Munich) [13] Chlorine Determination in Iron Artifacts by Prompt Gamma Activation Analysis (PGAA)

Archaeological iron artifacts often suffer from severe corrosion after their excavation. The presence of chlorine in the material is thought to play a major role in this process. Efforts to conserve such artifacts include treatments to remove any chlorine in the rust layer or in the iron itself, mainly by prolonged leaching in alkaline solutions or by heating. It is therefore important to determine the chlorine content of the finds before and after treatment in a non-destructive manner. Prompt Gamma Activation Analysis (PGAA), which determines the element content of objects by bombardment with thermal neutrons and observation of the promptly emitted gamma rays is unique in allowing such determinations for rather large objects. We report on first PGAA experiments yielding chlorine contents between 100 and 1500 ppm with excellent accuracy. The method can yield information on the efficiency of leaching methods, on the exact
location of the chlorine in the artifacts, and on the effect of Cl removal by heating in reducing atmospheres. PGAA may also be a useful general tool for archeologists to test recently excavated iron artifacts for their chlorine content in order to facilitate a prompt and appropriate conservation treatment.

[74] Longhouses and Peace Medals: Elaine Bluhm Herold and the Beginning of Contact Period Archaeology in Illinois  
Investigations of the various types of cultural entanglement that occurred between late eighteenth to early nineteenth century Native and Euro-American societies in eastern North American have increased over the past two decades. Elaine Bluhm Herold began investigating such sites in Illinois as early as the 1950s, long before other researchers in the state recognized their importance. This paper reviews her contributions to the development of contact period archaeology in Illinois, including her excavations at the Crawford Farm site, a major Native village associated with the famous Sac leader Black Hawk.

Wagner, Stephen (CEMML/CSU)  
[258] Social Media and the Process of Archaeological Commentary  
The proliferation of blogging and other social media platforms have allowed archaeologists to increase communication with the public as well as within the professional community. Blogs tend to follow certain themes including archaeological news, project updates, and archaeological methods. Despite our continuous calls that archaeology is more than just fieldwork or old things, many of our online presentations seem to focus around these topics. The Process Archaeology blog and twitter accounts were created as a way of discussing archaeological methods beyond the usual suspects of fieldwork basics. In the years since beginning this project, much has changed. The target audience has shifted from an advanced avocational public to entry-level post-graduate professionals, while the preferred delivery structure has changed from the soapbox blogging strategy to one considerably more conversational. As it stands now, the project may not reach its original goals, but the observations since its start can provide guidance for similar projects in the future.

[158] Holocene Climate Change in the Southern Maya Lowlands  
The modern climate of the circum-Caribbean region, including the Yucatan Peninsula, is determined by complex interactions of ocean-atmosphere systems from the both the Atlantic and Pacific. Elucidating spatial and temporal patterns of past climate variability is essential to assessing the role of these interacting forcing mechanisms. Holocene climate reconstructions from the Yucatan peninsula are particularly useful in understanding how extreme climate events, specifically multi-decadal droughts, may have negatively impacted the Maya civilization. Here we present an 8700-year record of environmental change based on stable isotopes, pollen, charcoal, and magnetic susceptibility. These proxy indicators enable us to distinguish anthropogenic from climate-induced environmental change and estimate the relative importance of each. Results from this study indicate a more humid climate during the mid-Holocene. A transition to drier conditions beginning around 6000 BP likely resulted from changes in solar radiation (precession effects). Higher frequency (≥ centennial) variability appears to be driven by climate dynamics originating from both the North Atlantic and the Tropical Pacific oceans. During the period from -4600 to 1000 BP, human activity was the primary cause of vegetation change and accelerated soil erosion.

Wakabayashi, Kunihiko (Doshisha University)  
[226] Society during the Yayoi Period of Late Prehistoric Japan  
This paper discusses a model of societies during the Middle and Late Yayoi Period of late prehistoric Japan (first century B.C. to second century A.D.). Numerous Japanese archaeologists regard Middle and Late Yayoi Period societies at the level of chieftdom, but such a simplistic model ignores considerable degree of regional differences at that time. It is likely that in fertile plains, where several large, core settlements and clusters of burial mounds existed, societies achieved some degree of social ranking. In these societies, however, there were few individual who may be considered as chiefs from a mortuary perspective. In several small plains where only one core settlement existed, we see a simple hierarchy between the core settlement and small temporary camps, but such a hierarchical relationship did not last
long. As a whole, Yayoi societies varied considerably in terms of degree of social evolution. This lack of social structure common to the Japanese islands makes it extremely difficult to apply neo-evolutionary model of band, tribe, chiefdom and state to the Yayoi societies. It is urgent to develop a model that can account for considerable differences in social complexity and simplicity from a region to another.

[10] Identifying American Native and European Smelted Coppers with pXRF: A Case Study of Artifacts from the Upper Great Lakes Region
In North America, archaeologists now routinely use archaeometric methods to investigate native copper ore sources and metalworking techniques of past peoples. Native copper was not smelted, unlike European copper objects that later became available to Native Americans during trading encounters. Differentiating the compositions of Native and European copper allows the recognition of possible "protohistoric" sites, where smelted European copper might be the only trade item present in the assemblage, likely obtained through down-the-line trade. Identifying native copper objects from sites later in time provides information about the persistence of traditional copper-working technology among Native American peoples who also were obtaining items originally manufactured in Europe. This paper assesses the reliability of portable x-ray fluorescence (pXRF) as a fast and effective method of identifying coppers, as compared with laser ablation – inductively coupled plasma – mass spectrometry (LA-ICP-MS). The technique was applied to artifacts from two archaeological sites in the Upper Great Lakes region. Results indicate that for differentiation between native and European copper types, pXRF can be used reliably, without sample preparation and despite surface corrosion, providing a non-destructive way to clarify European trade item distribution and continuity of native copper object use.

Walker, Debra (University of Florida)
[123] Life and Afterlife at Cerro Maya, Belize
June 25, 2014 will mark the fortieth solar anniversary of the first day of excavation at Cerro Maya, Corozal District, northern Belize. Along with Santa Rita, Cerro Maya was one of the first sites on Chetumal Bay to be excavated in the modern era. During seven seasons of investigation, the precocious nature of the Late Preclassic Maya community living there came into clearer and clearer view. As the beach front village, ballcourts, commercial dock and sculpted architectural facades were revealed, Late Preclassic Cerro Maya seemed extraordinarily advanced for its relatively small size, indicative of a prosperous, if short-lived, maritime trading monopoly. Preclassic Maya research in recent decades has demonstrated that Cerro Maya was not as precocious as once thought. Subsequent work, including radiocarbon assays, documents that the site's Preclassic occupation was shorter, later and more dramatic than previously thought. This paper will examine Late to Terminal Preclassic mortuary practices at Cerro Maya in light of recent work in northern Belize and elsewhere. Mortuary ceramics now housed at the Florida Museum of Natural History provide a previously unpublished data set for regional comparison.

[333] When is a Kiva a Social Actor?
Are ceremonial buildings causal social actors? If so are they solely integrative or, like people, do they contribute to the creation of some social relationships and to the decline of others? In such activities do they also facilitate flows of information that enhance or hinder social relationships? I argue in this paper that leveling the playing field and treating people more like objects and objects more like people can make clear the causal contributions both bring to human activities. In this behavioral approach to architecture I treat people and buildings as equal interactors that possess performance characteristics that impact social relationships. This approach by design recognizes that any interaction and associated performance characteristics could also be construed as flows of information between interactors. This symmetry of interaction as a behavior and interaction as communication is particularly helpful for study of ceremonial architecture. Typically such buildings possess performance characteristics that include facilitating communication between human interactors and nonhuman beings. I draw on both forms of analysis (behavior and communication) to study the causal contributions of kivas in use during the spread of the Pueblo Katsina Religion in the American Southwest during the late 13th and early 14th centuries.

[155] Using Geophysics for the Archaeological Study and Management of Historic Cemeteries
Studying historic cemeteries in an archaeological way often requires the initial steps of spatially defining the limits of that cemetery and the number of burials within it. Even “well-preserved” historic cemeteries are often heavily impacted areas; construction and erosion often destroy headstones and boundary fences, and even restoration efforts may remove or misplace headstones, making the correlation between cemetery records and the actual burials a best-guess. Geophysical surveys are arguably still the most effective and efficient means of locating and mapping unmarked burials in a non-invasive way, and are an important and complementary method for guiding excavations when exhumation is desired. In this presentation, we draw upon examples from historic cemeteries around the U.S. where geophysical survey contributed directly to the archaeological study of these cemeteries. Rather than simply showcase the utility of geophysical survey in locating unmarked burials, we seek to show how these data can be used to identify complex burial contexts (such as stacked or multiple burials), and correlate actual burials to above-ground headstones. The information generated from these surveys not only aids in preservation and management efforts, but often adds dimension to the complicated use-life and social history of these important places.

Walker, John (UCF Department of Anthropology)

[198] Refuge, Frontier, or Citadel: Mojos as a Political Landscape
Could the southwestern Amazon and the Bolivian Llanos de Mojos in particular be usefully thought of as a refuge, where different groups of people used the geography of seasonally flooded savanna to escape various states over the long term? James C. Scott has used the term Zomia to describe much of Southeast Asia as such a refuge, a mountainous region united not by any feature of language, kinship, agriculture, music, art or economy, but rather by a common history of resistance to various states over thousands of years, and many thousands of square kilometers. For Scott, these attributes are strongly affected by the political necessity of evading predatory states. Sketching his model, Scott draws explicit parallels to other regions around the world, including Appalachia and the Amazon. The long-term pre-Columbian history of Mojos is complex, and spatial analysis of earthworks, occupied forest islands and rivers suggests that integration with and isolation from larger networks were important in the past.

Walker, Danny (Wyoming State Archaeologist's Office)

[334] Incised Stone Artifacts from Wyoming
In 2006, a pecked stone was recovered from archaeological excavations at the Sand Draw Dump Site (48FR3123). An additional three incised stones were identified from the site during analysis of fire-altered rock from the site. Interest was immediately generated in other incised stones from Wyoming sites. A review of materials at the University of Wyoming Archaeological Repository (UWAR) revealed other incised and pecked rocks had been recovered from at least 14 other Wyoming sites, with the artifacts having been placed in the repository. The Wyoming Cultural Records Office has recorded at least 15 additional sites with incised stone artifacts, based on information provided from site forms. Numbers of incised or pecked stone artifacts per site range from four artifacts (two sites) to a single artifact. Several isolate incised stones have also been recorded in the UWAR collections. The markings include random
scratches (incisions), geometric figures, pecked designs and anthropomorphic figures. While this research has centered on incised stone, incised wood, bone and mammoth ivory items are also present in the repository. This research is yet another example of the research available which can be conducted on repository collections.

Wallace, Ian (Stony Brook University), Lynn Copes (Quinnipiac University), David Raichlen (University of Arizona) and Theodore Garland, Jr. (University of California Riverside) [16]  

Mobility as a Nexus of Biological Organization

It is well accepted by archaeologists that mobility is a critical dimension of human behavior, one that links economy, technology, and social relations. Perhaps less appreciated is that mobility is also a nexus linking aspects of biological organization, including anatomy, physiology, and genetics. Here, we introduce a novel experimental approach to examining the influence of mobility on biological organization using mice from a long-term artificial selection experiment for high levels of voluntary wheel running. In this experiment, selectively bred mice run nearly three times as far per day as non-selected mice. We propose that three general insights provided by this experiment about the dynamic relationships between mobility and biological traits (e.g., motivation, energy metabolism) may also apply to the network formed by mobility and cultural traits (e.g., trade, raw material procurement). First, an alteration in mobility will necessarily be associated with a cascade of changes to numerous traits directly and indirectly linked to mobility. Second, changing mobility will result in complex patterns of tradeoffs and constraints among affected traits. Third, ‘multiple solutions’ exist to altering mobility, such that various combinations of adjustments to traits networked with mobility can achieve the same behavioral outcome.

The Tempo and Process of Culture Change: Two Tipping Points in Hohokam Prehistory

Three great tipping points in Hohokam prehistory in southern and central Arizona share a common theme that has relevance to societies today: societal change is molded by cascading social processes that inevitably proceed and ultimately reach a point of no return. The thresholds have their origins in human emotional responses to varied stressors and are thereby shaped by individual and group psychology, as well as by population levels and density and various environmental variables. The archaeologically visible results of the three tipping points are village formation at the start of the Hohokam sequence in the sixth century A.D., the development of a revitalization movement and rise of the Ballcourt Society at the end of the eighth century A.D., and the fragmentation and reorganization of Hohokam society in the late eleventh and early twelfth centuries A.D. Here, the first two of these tipping points are compared and contrasted with the goal of reaching a deeper understanding of the tempo and process of culture change.

Waller, Steven (Rock Art Acoustics) [122]  

Pipers’ Stones: Archaeoacoustic Evidence Connecting Music and Megaliths

Ancient Cornish mythology links pipers to megalithic stone rings. Experiments demonstrate that two pipers can set up sound wave interference patterns that give the auditory illusion of a ring of stones casting acoustic shadows. Uninformed blindfolded volunteers circled around a completely empty large flat area containing only two sound sources emitting identical wavelengths of sound. Upon hearing silence in the zones of destructive interference alternating in space with loud zones of constructive reinforcement, the blindfolded participants independently described the scene as containing “pillars,” “archways,” “solid objects with openings,” “tall and wide objects blocking the sound,” or “a lot of boulders...larger rocks...when there was the gradual rise and fall of sound, I was thinking of a slanted rock that came up.” Each participant drew corresponding figures clearly showing a ring of objects, where in fact there were no obstructions. In separate experiments, quantitative measurements show the megaliths at Stonehenge radiate acoustic shadows outward in an arrangement mimicking interference patterns, as do other megalithic stone rings tested. These results suggest interference patterns produced by pipers in the past were attributed to mysterious rings of massive unseen objects, which served as blueprints inspiring the construction of megalithic rings.

Prestige, Power, and Paquime: Social Inequality and Health in the Casas Grandes Region of Chihuahua, Mexico

The Casas Grandes region of Chihuahua, Mexico, represents one of the most socio-politically complex
prehistoric societies north of the Mesoamerican heartland. Beginning with Charles DiPeso’s seminal excavations, multiple lines of evidence, including prestige goods and burial treatments, have been used to explore social complexity and inequality at the type site of Paquime. In this study, correlations between bioarchaeological and mortuary data from Paquime are used to test three hypotheses about the effects of inequality on human health and longevity. 1.) Does social inequality affect life expectancy, and the likelihood of reaching 70 years of age or more? 2.) Are high-status individuals less likely to suffer childhood physiological stress, or more successful in recovering from stressful episodes? 3.) Does social inequality affect access to subsistence resources? By combining recent advances in bioarchaeological age-at-death estimation with statistical techniques to estimate survivorship, lifetime expectancy, and body mass, this study demonstrates that there is support for all three hypotheses. Incorporating skeletal data into interpretations of social organization at Paquime yields a more nuanced interpretation of how social inequality affected the day-to-day experiences of its inhabitants.

Walling, Stanley (Community College of Philadelphia) and Jonathan Hanna (Pennsylvania State University)

Late Classic Commoner Ritualism and Its Implications for Interregional Exchange

The site of Chawak Bu’o’ob was a densely occupied Late Classic Maya community, the unassuming remains of which are distributed across the face of the escarpment of the Rio Bravo drainage in northwestern Belize. During the 2013 field season, an unworked conch shell (Lobatus gigas) - possibly a conch shell trumpet - was found within a poorly preserved house stairway at the site. Obsidian prismatic blade fragments, sourced by x-ray florescence to Central Mexico, were found in the same residential area that produced the conch as well as adjacent to a nearby cave in the site’s commoner Ballcourt complex. The presence of these high-status items in multiple non-elite contexts far from their sources corroborates the pan-Mesoamerican trade networks discussed by Shaw and others. Furthermore, it suggests that these interregional markets may have become more accessible to commoners during the transition from the Late to Terminal Classic periods.

Understanding Woodland Period Social Interactions through Integrated Analyses of Pottery

The heightened and geographically extensive interactions of the Woodland period were fundamental to the development and reproduction of societies. In contrast to rare and unique artifacts so often studied, Swift Creek Complicated Stamped pottery found throughout much of the lower Southeastern U.S. is arguably the premier material for the systematic study of Woodland interactions. The unique impressions of individual carved wooden paddles are often found on pottery at multiple sites, lending an unparalleled level of detail and spatial resolution to social connections. Furthermore, the distribution of vessels potentially reflects a broad range of interactive practices among a large proportion of past populations rather than only the occasional practices of a few individuals. As part of a research program that uses integrated materials analyses of pottery to identify patterns of social interaction, this poster presents results of Neutron Activation Analysis and petrographic analysis of several hundred samples. More than two dozen assemblages were sampled from sites distributed across Florida and Georgia and dating between AD 200 and 800. Results indicate that interactions were geographically extensive, but clearly most intensive along particular corridors.

Settlement and Exchange During the 19th Century Illegal Slave Trade in the Rio Pongo, Guinea

For millennia, West Africa has remained a locus of dynamic cultural, political, and economic interactions. Throughout the first three centuries of the transatlantic slave trade, few Westerners settled the interior of this region, with most economic exchange occurring at coastal forts and trading posts. After the majority of Western powers agreed to abolish the slave trade in the early 19th century, an illicit trade developed through the opening of new markets with Europeans and Americans establishing smaller trading lodges or ‘factories’ in strategically isolated locations such as the Rio Pongo region of Guinea. As traders settled in these coastal hinterlands, new power relations were created in the local communities through the exchange of human chattel, material goods, and socio-cultural ideas. Archaeological investigations at three 19th-century illegal slave-trading lodges along the Rio Pongo reveal the complex social and economic networks and intercultural interactions that characterized this landscape. This paper integrates
documentary, archaeological, and geospatial data to specifically examine local patterns of settlement and exchange during this period, situating these sites within larger systems of political, economic, and cultural entanglement.

Walsh, Matthew
[290] Assessing Generation-scale Shifts in Subsistence Practices over time at Housepit 54, Bridge River Site (EeR4), British Columbia, Canada
Rarely do archaeologists have the opportunity to view change in subsistence practices occurring within a household on a potentially inter-generational scale. The stratified floor sequence from Housepit 54 at the Bridge River Site, south-central British Columbia, provides just such an opportunity. An analysis of archaeo-faunal remains across six floors, spanning a roughly 150 year period (ca. 1250-1400 BP) examines trends in animal resource exploitation over time. A variety of zooarchaeological measures including abundance indices are used to determine the driving force(s) behind changes in the assemblages. More specifically, this study uses zooarchaeological data to test hypotheses concerning the effects of cultural transmission and contingent ecological and demographic factors on animal resource procurement and processing decisions.

Walter, Tamra
[119] Native Homelands and Foreign Frontiers: Re-examining Native and Spanish Interaction in the South Texas Missions
More than 30 Spanish missions were established in Texas during the colonial era, nearly half of which were founded in south Texas. Archaeologists studying these missions rely on the material record to identify the presence of Native groups with particular attention paid to technological changes in “Native” artifacts and the physical layout of the mission compound. Making sense of the Native mission experience based on technological changes and spatial arrangements is one of the many challenges faced by archaeologists. More often than not, the mission system is discussed as a frontier institution established by the Spanish overshadowing the fact that for the nomadic groups of South Texas, the missions and presidios were an intrusion in their homeland. Each group responded differently to the Spanish and dealt with the mission system in various ways dictated by their own political and social motivations. Using the Espiritu Santo Missions as an example, the archaeological record is re-examined in light of these concerns. Specifically, archaeological investigations at the third and fourth locations of the mission provide an opportunity to re-examine the Spanish Frontier from a different perspective.

Walters, Sarah
Topper (38AL23) – a quarry site, situated along the Savannah River’s Piedmont-Coastal Plain transitional zone – validly stands as one of the most important archaeological sites in the Southeastern US. Though the subject of some controversy, Topper is a true rarity, yielding a complete sequence of artifacts – from Paleoamerican to Historic. As such, it is of great importance that all forms of artifact-potential be systematically recovered and analyzed. This presentation addresses the findings of a paleoethnobotanical study, conducted at Topper over the course of the last three years. Because the cost-benefit of systematic paleoethnobotanical investigation is sometimes questioned, this study aims to convey the broader scientific utility of such research, extending beyond description-based subsistence studies. Carbonized plant remains, all recovered from the context of sandy/acidic soils, have yielded several AMS dates – including one of the oldest associated with Southeastern Paleoamerican lithic materials (10,958 +/− 65 B.P. (AA-100294)). It follows that the preservation environment is often archaeologically misunderstood and that recovery of plant-artifacts, suitable for radiometric dating, is possible. Furthermore, the integrity of Topper’s vertical stratigraphy is demonstrated, allowing for the construct of a more absolute chronology of this site-type, previously thought dateable only by comparison to regional sequences.

[79] Fighting with Soddies? A First Look at Signaling and its Effectiveness in Homesteading Contexts, Sand Hills region, Central Plains, USA
People strategically use “stuff” to signal aspects of themselves, their ethnic identity and status. Can we
see this behavior in homesteading contexts, with limited inventories of material culture? We report on our study of Custer Co (Nebraska) homesteaders and how they deployed material culture, relying on the photographs of Solomon Butcher, coupled with documents and archaeological evidence, to gauge the quality of the emitted signal. Documents on proving up and vital statistics are used to assess success. We examine this question in the contested Sand Hills region, rife with pastoralist-agriculturalist and ethnic rivalries.

Wang, Yanxi (University of Georgia) [235] Agriculture and Regional History of the Guan River Valley in China

The Guan River regional systematic survey has revealed regional settlement pattern and history in the Middle Guan River Valley near Xixia, Henan from 5000 BC to the 1500 AD. The changes in the settlement pattern reflect complex processes involved in the history of agricultural intensification in this environmentally diverse region. During the Neolithic period, the regional population grew slowly. Settlement location choice shows that the transition from foraging to farming lifestyle was slow and gradual. In the Easter Zhou period (770-221 BC), the geopolitical importance of the Guan Valley led to rapid growth of population, occupation in mountainous area, and an emphasis on riverine transportation. In the Qin and Han period (220 BC-581 AD), the land exploitation for agriculture reached the peak, accompanying with an a transformation in village residential pattern to a more disperse style.

Ward, Christine (Statistical Research, Inc), Mark Mitchell (Paleocultural Research Group) and Catherine Cameron (University of Colorado) [333] The Role of the Bluff Great Kiva in Temporal Perspective: From Integration to Dissolution of Chaco-era Communities

Chaco-era great kivas integrated the communities around them. But what happened after Chaco’s collapse? Was the purpose of great kivas adjusted to reflect these larger changes occurring around them? Did the social significance that Chaco-era communities invested in great kivas linger, or were they re-imagined and re-purposed? In this paper, we review the evidence at the Bluff Great Kiva for its role – and perhaps changing role – within the Bluff Great House community and within the larger northern San Juan region. During the Chaco era, the Bluff great kiva was a setting for community-wide activities. In the post-Chaco era, the community and great house continued to be actively used, though both the great house and great kiva were remodeled repeatedly. Evidence from the great kiva’s northern antechamber points to an increasingly domestic use of that space. Did the social significance people attached to the great kiva also change? We review the evidence for the changing role of the Bluff great kiva space, both directly through excavation data as well as through comparison with other great kivas in great house communities of the northern San Juan region.

Warinner, Christina (University of Oklahoma) [83] Ancient Biomolecules and New Possibilities in Mixtec Archaeology

Over the past ten years, major technological advances in genomics and proteomics have opened up dramatic new possibilities in archaeological science. This paper discusses recent developments in biomolecular archaeology with an emphasis on emerging biomolecular tools for investigating the effects of the Spanish entrada on Mixtec polities.

Warmlander, Sebastian (Division of Biophysics, Stockholm University), Vanessa Muros (UCLA/Getty Conservation Programme) and David Scott (UCLA/Getty Conservation Programme) [104] Characterization of Some PreColumbian Gold Wires from South America

In this study, excavated gold wire and other small gold objects from the Calima cultural region in modern-day Colombia have been analyzed with x-ray fluorescence spectroscopy (XRF), scanning electron microscopy with energy-dispersive spectroscopy (SEM-EDS), and with conventional metallographic techniques. The results show that these gold artifacts are made from ternary gold/silver/copper alloys, where no surface enrichment of gold has taken place. A number of small circular wires were studied with respect to the manufacturing technique. Although some had been cast to shape, most wires had been created using the block-twisting method. These results improve our still limited understanding of pre-Columbian gold working and metal wire manufacturing.
Warner, Vincent (AMEC Earth & Environmental)  
This poster explores the temporal aspect to the location of Late Woodland pottery lip decoration; that is, does the location of the lip decoration (interior, crest, and exterior) relate to changes through time in the east-central portion of Missouri. Additionally, this research looks at the possible relationships among decorative techniques. These goals are accomplished through the seriation of feature pottery assemblages, specifically through wall-thickness time-series curves (based on the work by David Braun) and correspondence analysis of decorative elements. A commonly held notion is that in eastern Missouri and adjacent Illinois, lip decoration during the Late Woodland period moved from the interior margin to the crest and then to the exterior margin. If the location changes with time during the Late Woodland, then there might be a temporal relationship to the decoration itself. As Braun established in the Lower Illinois River valley (and Michael O’Brien confirmed in east-central Missouri), cooking vessels were designed and manufactured to be generally thinner through the Woodland period due to coevolutionary reasons. The focus of this research is the application of the wall thickness to chronology as related to trends in pot decoration.

[140] Exploring Chultun Functionalities: An Experimental Assessment of Food Storage in Chultuns at Uaxactun, Guatemala.
Research was focused on replicating particular principles of Dennis Puleston’s food storage experiment in chultuns at Uaxactun, Guatemala. Investigations were conducted during the 2013 Uaxactun-Sahi field season under the supervision of the Slovak Archaeological and Historical Institute (Sahi). The experiment was conducted over 47 days, with observation made every 3-4 days depending on the climate and rain. Food observations were made by weighing, photographing, and detailed recording of decomposition conditions. The eight varieties of foods utilized were macal, camote, cacao, yucca, dried corn, smoked corn, black beans, and red beans from Belize. Results showed great preservation of the camote and macal following the experiment. The yucca and both types of beans decomposed completely with a high presence of fungus and mold. Whereas the other foods of cacao, dried corn, and smoked corn all presented varying levels of preservation, though a percentage of each food was still edible following the experiment. For future experiments the environmental conditions should be closely monitored including the humidity index due to their influence on the overall preservations. Alterations should be made to the types of foods used and measurement of the water content of each food would be vital to understanding their preservation abilities.

Warren, Daniel  
Underwater archaeologists have used remote sensing technologies to locate shipwreck sites for decades. Wreck sites located in waters less than 300 feet (91 meters) are regularly documented through diver surveys. Investigating wrecks beyond these depths, however, have proved problematic since the technology necessary was expensive and time consuming. In 2001, the first commercial Autonomous Underwater Vehicle (AUV) began operations in the Gulf of Mexico. Originally developed to support oil and gas exploration operations in deepwater regions, archaeologists soon realized that the AUV was also an ideal tool for deepwater shipwreck investigations. Over the past 13 years, AUVs have changed the face of deepwater archaeology in the Gulf of Mexico and around the world. This paper will discuss the AUVs used by C&C Technologies, Inc., the author's employer. It will include an overview of the types of geophysical and optical systems used on C&C’s AUVs, look at AUV investigation methodologies, and highlight past AUV discoveries and potential future research.

[102] An Investigation of Human Dietary and Mobility Patterns at the Late Neolithic Burials of Bolores (Torres Vedras, Portugal) Using Isotopic Analyses
The archaeological record of the Late Neolithic and Copper Age in Iberia provides evidence of large population aggregations around fortified and ditch-enclosed settlements that are associated with emerging craft specialization and long distance trade. However, in southern Iberia the impact of these changes on social differentiation remains unclear, in part because the commingled nature of human remains in Late Neolithic and Copper Age collective burials limits our ability to link burial goods with specific individuals, impeding our understanding of social differentiation, status, or individual identity in these late prehistoric agrarian communities. Bioarchaeological analyses, however, provide another avenue of investigation concerning individual life histories, as dietary, mobility, and health-related information can be gathered from human skeletal remains. This study uses carbon ($\delta^{13}$C), nitrogen ($\delta^{15}$N) and strontium isotope ratios ($87\text{Sr}/86\text{Sr}$) taken from human skeletal remains recovered at the Late Neolithic and Copper Age (3500-2000 BC) collective burial of Bolores (Torres Vedras, Portugal) to investigate if variations in dietary and mobility patterns during the lifetimes of these individuals can be used to better understand social differentiation during this dynamic period.

Waterman, Anna [241] see Mack, Jennifer

Joe and Ruth Cramer created the North Star Archaeological Research Program in 2002. Its mission is to investigate sites of the first people who entered the Americas and train the next generation of researchers. North Star has focused its resources on the investigation of the Late Pleistocene exploration period of the Americas, specifically Clovis and the people who were here before them. North Star funds have been used to conduct major field excavations, date early sites, and help many students. The knowledge generated by North Star and the other archaeological programs, and the students who have benefitted from these programs are the archaeological legacy of Joe and Ruth Cramer.

Watkins, Joe (National Park Service) [304] Training the Next Generation of Tribal Historic Preservation Officers
Tribal Historic Preservation programs offer an opportunity for tribes to take an active role in the national historic preservation program. Unfortunately, all too often people who take on the role of the tribal historic preservation officer (THPO) have minimal training in the process of managing cultural resources or in running a successful tribal program. While tribal people can gather training in the "nuts and bolts" of the processes involved, it is important that the tribal preservation official understands the perspectives of those who manage the national program. Teaching the "next" generation of THPOs should therefore involve not only grounding in the legal processes, but also mentoring to allow "new" THPOs to better cope with the sometimes conflicting perspectives on similar issues held by tribal individuals and other managers. Using examples from an academic course offered in the Native American Studies program at the University of Oklahoma, the presenter will offer examples and techniques on helping tribal people not only to identify conflicting perspectives and but to create innovative ways of dealing with those conflicts.

Watkins, Rachel (American University) [126] The Embodiment of Inequality: Osteobiographies from the Cobb Human Archive
This paper highlights analyses of individuals who are a part of the Cobb Human skeletal and documentary archive housed at Howard University. Individuals with and without a skeletal presence are included in the discussion for the purpose of demonstrating the demographic breadth of the original skeletal collection, as well as the associated breadth of social formations bearing upon health and disease patterns identified in the sample. The relationships between the social formations in which people were embedded and their health are explored by way of a model developed by Watkins and Muller for engaging in a critical and humanistic study of the sample. The model calls for reliance upon census and ethnographic data when possible, as well as simultaneous biocultural investigations of individual and group health within the collection. The paper argues that this approach provides a unique opportunity for exploring how individuals and groups within the collection existed as subjects and agents who developed
strategies to resist structural constraints.

Watkins, Christopher (Arizona State University)  
[182] The Bounded Alliance: Cooperation and Conflict in 14th Century Central Arizona  
Settlement patterns have often served as the basis for arguments about alliance boundaries in the American Southwest, particularly as communities continued to coalesce into increasingly larger aggregates throughout the Late Prehistoric period. Both emergent and persistent alliances would have required persistent communication, interconnectivity, and regular maintenance, phenomena that should be manifested in the archaeological record. I take settlement size and spatial distribution as starting points for hypothesized alliances in 14th Century central Arizona, and test the boundaries of the proposed alliances with multiple lines of evidence including indicators of exchange as well as ritual and community integration within the context of boundary theory.

[125] Recent Investigations at Guantanamo Bay, Cuba  
Cuban prehistory had long been a subject of interest to North American archaeologists, including groundbreaking work by Rouse and Harrington in the 1940’s. However, the Revolution left North American scholars unable to continue work within the country. Much subsequent work has been done throughout the Antilles, but Cuban studies have been left without an update, including work on ceramic series and typologies, and lithic tool types and manufacture. Throughout this time, the United States maintained control of lands in southern Cuba, at Guantanamo Bay Naval Station (GTMO). In 2004, Navy archaeologist Bruce Larson and graduate students from Florida Atlantic University collaborated on excavation and subsequent analysis of archaeological sites at GTMO. The 2004 fieldwork involved excavation and surface survey at four of the prehistoric sites identified in 2003. The paper presents the analysis of the artifacts, which include ceramics, lithic debitage, and shell, and speculates on how these artifacts are tied to cultural groups and time periods of Cuban prehistory. Sites included a multi-use site, with radiocarbon dates linking the site to the Ceramic Period and one site possibly linked to the Archaic period. Artifacts recovered from these sites reveal intriguing patterns across time at Guantanamo Bay.

[177] Excavations of Earthen Mounds in the Mangroves at the Paynes Creek Salt Works, Belize  
The ancient Maya along the coast of Belize produced salt by evaporating brine in pots over fires, evidenced by dense accumulations of briquetage—the remains of pots used in the evaporation process. During the 2012 field season, two earthen mounds were excavated as part of project excavating...
underwater sites associated with wooden buildings stunningly preserved by mangrove peat below the seafloor. Salt was produced in massive quantities inside of buildings at the underwater ancient Maya salt works. Lacking at these underwater sites is any evidence that the salinity of seawater was enriched by leaching brine through salty soil or by solar evaporation before the brine was heated in pots over fires—virtually universal in ethnographic and historic case studies elsewhere. The mounds at Witz Naab and Killer Bee are some of the few remaining onshore remnants of the Paynes Creek salt works. We describe the excavations of two earthen mounds and evaluate their use and their relationship with the nearby submerged salt works.

Flintknapping in New England: Stone Tool Analysis at the Rebecca Nurse Homestead, Massachusetts

Prehistoric occupation at the Rebecca Nurse Homestead (RNH) in Danvers, Massachusetts during the Late Archaic and Early Woodland periods occurred frequently but not consistently, suggesting that it was used as a temporary site, not as a more permanent habitation locale. The primary raw material used at RNH was Marblehead rhyolite, which made up 95 percent of the sample. Since the material is local, the lack of early-stage flakes implies that the residents were knapping their tools at the source site and then retouching them at RNH. The results of my analysis at RNH were compared with published data from seven other sites in New England: Wheeler’s site, Nelson Island, Clark’s Pond, Hofmann, Foster’s Cove, Seabrook Marsh, and the Neville site. This research presents preliminary conclusions about the function, seasonality, and activities at RNH and identifies areas for future exploration.

Estimating Sex of Contemporary American Individuals through Metric Measurements of the Petrous Portion

The current study determines if metric measurements of the petrous portion of the temporal bone are an accurate method of sex estimation for contemporary American individuals. Skeletal data utilized in this study were derived from individuals with intact petrous portions sampled from the William M. Bass Donated Skeletal Collection at the University of Tennessee Knoxville and from the Texas State University Donated Skeletal Collection. Methods utilized in this study were modeled after Kalmey and Rathbun (1996) who compiled 9 measurements of the petrous portion and applied them to documented historic individuals from the Robert J. Terry Anatomical Skeletal Collection. General Linear Model MANOVA procedures revealed a significant relationship between metric measurements and sex. Discriminant function analysis and stepwise discriminant function analysis procedures resulted in sex estimation accuracy rates between 60% and 68%. This research shows that the petrous portion can be used as an estimator of sex and can be an additional method in the arsenal of forensic anthropologists and historic bioarchaeologists alike in the absence of other key osseous remains.

Exploring Chaco Canyon’s Invisible Industry: An Experimental Approach to the Study of Bone Tool Use-Wear and Perishable Craft Production Patterns at Pueblo Bonito

During the Bonito phase (850-1140 C.E.), dispersed farming communities in and around Chaco Canyon, New Mexico emerged as the core of a regional network of unprecedented size and scope that flourished for three centuries. Studies have shown that while large quantities of ceramics and raw materials flowed into the canyon, there is also strong evidence for local production of textiles, basketry, cordage, rabbit-fur and turkey-feather blankets, and finished hides. By examining bone tools, a specific class of artifacts essential to the manufacture of these perishable products, this project traces changes in the scale and intensity of perishable craft industries that are otherwise largely invisible archaeologically. Building on recent breakthroughs in the analysis of microwear, this research applies confocal laser scanning microscopy and texture analysis techniques drawn from the field of surface metrology to identify use-wear patterns on experimental, ethnological, and archaeological bone artifacts. Our approach utilizes multi-scale geometric characterizations of surface wear to identify statistical similarities as a function of scale. The introduction of this quantitative approach to the study of microtopography holds significant potential for advancement in use-wear studies by reducing inter-observer variability and identifying new parameters useful in the detection of differential wear-patterns.

Wattenmaker, Patricia (University of Virginia)

Hinterland Communities, Rural Elites and the Limits of State Power in Upper Mesopotamia

Settlement patterns and archaeological data on production and exchange provide a window into relations
between centers and villages in the context of emergent urbanism. This overview of early to mid-third millennium upper Mesopotamian societies highlights the dynamic interplay between large and smaller sites in terms of the tributary economy, exchange, and population movements. Available evidence indicates that relations between centers and smaller sites were simultaneously complementary and antagonistic. Hinterland communities were unevenly impacted by increased political centralization and urbanism, with some villages well situated to prosper as urban systems formed. Their settlement trajectories underscore both the agency of rural communities and the limits of state power. The complexity of urban-rural relations contributed to the highly fluid political and economic landscape that characterized Upper Mesopotamia during this time.

Time Team America: The Use of Public Archaeology as a Gateway to Science

A second series of the PBS television program Time Team America (TTA) was funded entirely through a NSF Informal Education grant using "Archaeology as a Gateway to Science" to expose, engage, and inspire underserved youth in Science, Technology, Engineering, and Mathematics (STEM). The format included three days of filming and a concurrent five-day field school for STEM youth. Practical benefits of the project included the development of geophysical survey protocol and resultant data that contributed to the overall research agenda at each site and to guide excavations during filming and throughout subsequent years. During the filming and field schools, a diverse range of people participated and were exposed to all aspects of science-based archaeological methods. The public archaeology approach encouraged direct engagement with community members to help them visualize and articulate the integrated history of their community and explore archaeology as a gateway to science. Major involvement from a variety of agencies and groups demonstrated cross-organizational cooperation toward a common goal of preservation and methods through which to achieve this goal. Lastly, a website was designed to provide a resource for further public dissemination on archaeological methods while revealing in-depth information on the history and diversity of the shared past.

Watts, Christopher (University of Western Ontario) [159]  
Late Woodland Earthen Enclosures and the Cultivation of Place

Found throughout the Great Lakes and environs, Late Woodland earthworks have been the subject of archaeological investigation since at least the late nineteenth century. While typically considered a site type and understood to have served a single function (e.g., as defensive installations or demarcations for ritual activities) such enclosures are often unique, mutable, and enigmatic. Drawing upon the archaeology of the eastern Midwest, and inspired by recent investigations at the Cedar Creek Earthworks in southwestern Ontario, this paper attempts to displace some of the more imperious tropes concerning Late Woodland landscape use and transformation. Born of particular lifeworlds and intimately tied to localized histories of inhabitation, it is argued that earthen enclosures were intended to engender particular topographies and materials as part of a broader commitment to place and fabric of Late Woodland dwelling.

What's Grog Got to do With It? Ceramic Temper, Technological Processes, and Social Change in the Precolumbian Midwestern United States

In the study of the Precolumbian Eastern United States, ceramic typologies classifying temper treatments have been foundational in defining chronologies and culture groups. Specifically in the Midwest region, grog tempering has been typically recognized as a Middle (A.D. 1-400) and Late Woodland (A.D. 400-1000) culture trait and shell tempering as a diagnostic hallmark of the subsequent Mississippian culture (AD 1000-1600). Ceramic analyses from this region often downplay or dismiss observed mixed tempered materials as non-existent or incidental admixtures. This analytical practice often masks the variation of tempering treatments in these assemblages as well as masking the social constructs that inform ceramic production. In this paper, we suggest that identifying and including mixed tempering in analyses and interpretations is key for better understanding the processes of Mississippianization and the material manifestations of being Mississippian. Directly addressing mixed temper treatments, we present ceramic analyses from Late Woodland Yankeetown Phase (A.D. 800-1100) sites in southwestern Indiana and the
Late Mississippian Period Common Field site (A.D. 1200-1275) in southeastern Missouri, and reposition mix-tempered technologies as negotiated practices, whereby learned, habitual actions related to the production of pottery are entangled in the historical processes associated with the rise and fall of Mississippian polities.

Dialectics of Power in Peruvian Slavery: Preliminary Findings from the Archaeology of the Jesuit Wine Estates of Nasca

A number of historical studies since the 1970s have brought to light the practices and administration of the coercive institutions of slavery in the colonial Andes. However, many questions regarding how power was brokered in the spatial and material conditions of slavery among the significant population of enslaved Afro-Andeans in the viceroyalty (and young Republic) of Peru, remain unasked and unanswered. This paper discusses advances from the ongoing Haciendas of Nasca Archaeological Project, the first such project in Peru emphasizing a principal research agenda on the material culture of African descended peoples. We discuss the preliminary results of walkover and geophysical survey, excavation, and material analysis on two Jesuit wine-growing estates (and their annexes) centered in the Ingenio Valley. In addition to exploring how space and the built environment structured and were structured by the labor regime, we examine particularly how power was brokered at the levels of agroindustrial and domestic production. This leads to a better understanding of development of the institution of the hacienda by multiple actors, highlighting the material actions of enslaved laborers of (mostly) sub-Saharan African origin.

Weber, Jill (The University Museum of Archaeology and Anthropology, UPenn), Kimberly D. Williams (Temple University) and Lesley Gregoricka (University of South Alabama)

Animals and the Changing Landscape of Death on the Oman Peninsula, 3rd Millennium BC

Animal bones form large components of Early Bronze Age burials in Syro-Mesopotamia, which reflect concepts of death, vestiges of funerary ceremony, and artifacts of life. However, in contemporary burials from the north-central Oman Peninsula, finds of faunal remains remain scarce in third millennium BC Bronze Age tower tombs. At the Al Khubayb Necropolis near Dhank in the Sultanate of Oman, transitional tomb forms (dated to the later Haft and early Umm an-Nar periods) have yielded new information about rare instances of animal bones deliberately interred within human burials. Despite their scarcity, the context of these bones - particularly their associations with individuals of a certain age and sex - offer insight into a transitional mortuary landscape and its relationship to the living. These data will be assessed in relation to regional examples of faunal inclusion elsewhere in southeastern Arabia and their significance considered with regard to the practice and ritual meaning of faunal interments.

Fired Twice for Blogging and Social Media: Why CRM Firms a afraid of social media

Three months after starting my first blog I was fired for a post about a project I was on. Two companies and five months last I was fired for a tweet about a project. Blogging and social media have become indispensable tools for tech-savvy archaeologists to learn, stay informed, and educate the public and our peers about what we do and why it's important. Many other industries have embraced social media while many CRM firms still treat social media as something to be avoided and controlled. What are they afraid of? Are the concerns valid? How can we change the perception of social media among firm owners?

“A Perfect Hive of Human Beings”: The Archaeology of Post-Famine Irish Immigrants in Boston’s North End

During the eighteenth century, the people of Ireland suffered through long periods of famine. Leaving Ireland in the millions, many settled in the working-class neighborhoods of North American port cities
such as Boston’s North End. They became part of the cultural and economic transformation of the North End from a predominantly middle class English-American neighborhood to an industrial center for the waves of working class immigrants who arrived in Boston daily. In 1880, the Clough House, which in earlier times was home to only one or two families at a time, housed a staggering 22 individuals from seven families in three meager apartments. Here, Irish immigrants shared their living quarters with the American-born working class in a diverse and ever-changing neighborhood. This presentation combines recent archaeological excavations at the Clough House with in-depth archival research to provide new insight into this volatile period of Boston’s history. It retraces the paths of the Irish who emigrated during the famine years, explores their lives in the tenements, and connects the material culture to their struggles with class and ethnicity in a new, American, environment.

Webster, Laurie (University of Arizona)

[294]  Sandals, Baskets, and Other Perishable Technologies of the Southern Chuska Valley

Recent archaeological investigations at late Basketmaker III burned pit structures in the southern Chuska Valley have yielded surprising quantities of carbonized perishable artifacts that complement data from better-preserved perishable assemblages from rock shelters to the north and west. Analyses suggest that groups in the southern Chuska Valley were as heavily invested in the use and production of complex twined sandals and coiled baskets as their northern neighbors and may have engaged in ritual practices with links to Chaco Canyon. In this presentation, I synthesize perishable data from several recent mitigation projects in the southern Chuska Valley and explore the social implications of these findings.

Wegener, Robert (Statistical Research, Inc.)

Statistical Research, Inc.’s., mitigation of a proposed solar-power-array at Luke Air Force Base involved excavating 44 contiguous acres, sampling ca. 3,000 features, and documenting the largest and most diverse Middle Archaic occupation in Arizona to date. Site function and socioeconomic organization varied from a resource procurement staging and processing locale frequented by task groups to a seasonal habitation including multiple contemporary structures built and used by family groups. The increased occupational intensity signaled by the repeated but short-term establishment of seasonal habitations coincided with short periods of increased precipitation, aggradation, and biotic productivity. On-site subsistence is particularly interesting because it involved significant investment in a formal ground-stone technology applied to nearby native plants, and this subsistence pattern persisted for millennia before and after the arrival of maize horticulture in surrounding locales at ca. 2100 B.C. At Luke AFB, all this transpired in a lower-bajada setting that is traversed but not occupied in most Middle and Late Archaic land-use models. Ongoing analyses and current project results are used to present these newly documented aspects of settlement, subsistence, and social organization during the Middle-to-Late Archaic transition in the Sonoran Desert.

[337]  Modeling Environmental Effects of Maya Legacies from LiDAR-Derived Topography

Mesoamerican rainforests are remnants of one the largest natural reforestation events of the last millennium. Abandoned settlement and agricultural engineering features of the Maya, that lay largely hidden beneath the dense tropical forest canopy, are being revealed with the use of airborne LiDAR remote sensing. Around the hills and valleys of Caracol, a significant archaeological site in Belize, lies an extensive network of terracing that once supported over 100,000 people. The anthropogenic manipulation
of the landscape has been shown to affect contemporary tree species composition and general forest structure (i.e., height, biomass, canopy openness). Using the LiDAR-derived digital elevation model (DEM) coupled with topographic modeling routines, we were able to estimate the influence of terracing on hydrological flows and erosion forces, which may have been the fundamental cause of the ecological consequences. Though simulated soil wetness indices were somewhat higher on steep terraced slopes, sediment transport indices of terraced areas were lower regardless of slope. This pattern suggests that the primary function of the Maya terracing was soil conservation and may be the driver of the present-day forest stand differences.

[327] Solar Eclipses: Events Marking the Center of the Mississippian Landscape
Solar eclipses are dramatic, widely observable, recurring events for which precise dates, times, and locations of occurrence are known. Despite their potential to have influenced prehistoric beliefs and behavior, and their utility as temporal markers, solar eclipses have received little attention from southeastern archaeologists. During the Mississippian period, more than 50 total and annular eclipses occurred, including events on December 3, 1062; March 7, 1076; July 1, 1079; August 13, 1151; September 14, 1205; and June 13, 1257. The number, magnitude, and duration of eclipses varied appreciably by location. While total and annular solar eclipses are rare, with an average combined recurrence rate of 140 years, some sites witnessed more frequent, longer, and greater-magnitude eclipses. This paper examines the correlation between site locations and major solar eclipse events, and it hypothesizes that Mississippians identified and preferentially occupied ‘central’ locations defined by eclipse paths, and that those celestial events demonstrated the ‘centrality’ of particular places and affirmed beliefs about the favorability of particular places within the landscape and cosmos. The concept of centrality as marked by solar eclipses is widely expressed in Mississippian iconography. Examples in engraved shell, copper, ceramics and rock art are briefly discussed, and interpretations of them reconsidered.

Weismantel, Mary (Northwestern University)

[25] Heads as Artifacts
Severed heads are omnipresent in Andean iconography and in the archaeological record, where they are found in mortuary depositions and in household caches. Human and animal heads and other body parts were also re-purposed as artifacts with a variety of purposes; this paper focuses on the fashioning of headdresses, drums, flutes, and drinking vessels, and on the creation of ceramic effigy heads that served as containers for liquids. In the first half, I use Amazonian ethnographic data as well as theoretical insights from Strathern, Mauss and others to argue for an Amerindian conceptualization of the body as an assemblage of material interactions with others, suggesting that pars pro toto may not be the best way to understand the post-mortem use of body parts. In the second half, I analyze Moche ceramic effigies of human body parts to suggest a possible dualism in Andean thought between air and liquid. This distinction may be visible in the material record, and can be used to interpret the fact that some artifacts made from or representing body parts, such as bones and skulls that whistle, are air-filled, whereas others, such as the effigy pots, are liquid-filled vessels.

[28] Social and Biological Variables in a Case Study of Commingled Remains
The social context of commingled remains may enrich interpretations of osteological data. We incorporated this approach in our study of three skeletons recovered from a common grave, located 100m south of a cemetery in present-day Bucharest (Romania), dating to 1550-1650 AD. We collected qualitative and quantitative data on sex, age, ancestry, trauma, and social context. The remains represented three adult males (~25-50 years at death). Ancestry data suggests one was European, one Asian, and one African. All had multiple healed and perimortem traumas. Two had lead shot in the neck area; the third had a projectile point in the same area and was likely beheaded. Orientation and commingling of the remains suggests that the bodies were buried unceremoniously. The history of the area, and the ancestry findings, reflect the biological diversity of warring entities contesting for control of area when the three were buried. The sex and age results conform to the demographics of period armies. Their bones disclose lives marked by injuries and violent death, likely in armed conflict and/or execution.
The ancestry and social roles of these three individuals likely contributed to their deaths and the burial context outside of the local community cemetery.

Welch, Daniel (Texas A&M University) and Suzanne Eckert (Texas A&M University) [242] Do Dates Connect Culture? Rethinking Identity at Aganoa, a Lapita-Aged Plain Ware Site on Tutuila Island, American Samoa.

Excavations at Aganoa (AS-22-43), Tutuila Island, American Samoa have uncovered a living surface with a radiocarbon record and associated material culture and that dates to the Late Eastern Lapita era (2700-2300 BP). Although no dentate-stamped pottery was found on this surface, the chronological placement and other material culture resembles that of the Lapita cultural complex found elsewhere in Western Polynesia. This early plain ware producing community at Aganoa forces us to question what Lapita means in Samoan archaeology. The paleo-topography, living surface, radiocarbon dates, and material culture associated with the Late Eastern Lapita era component of Aganoa is described here, with a discussion of its implications for how we understand Lapita and the development of Polynesian culture in Samoa.

Welch, Jacob (University of Kentucky) [305] The Maya Toll: Regulation, Use and Administration of the Ucí-Cansahcab Sacbé

Isolated on the outskirts of the Ucí, an ancient capital in Yucatan state, Mexico, rests a giant megalithic platform locally known as Hubichen. First mapped in 2009 as part of a survey along the 8km long intersite sacbé between Ucí and Kancab, Hubichen is the largest structure in the survey. Its proximity to the sacbé and its seclusion from other mounds in the area have sparked questions on the use of this structure and its involvement in the regulation, supervision and administration of the portion of the sacbé between Ucí and Kancab. Recent broad horizontal excavations in conjunction with phosphate data allow to glimpse at the purpose of this platform and its relation to Ucí’s growing political domain in the Early Classic and regional integration overall. Due to its Post-Classic re-use, Hubichen also provides insights on Late Prehispanic occupation and ritual within the Northern Maya Lowlands of Northwestern Yucatan.

Welker, Martin (Penn State University) and Patricia Lambert (Utah State University) [12] Subsistence and Trauma: The Southeast in Perspective

Human skeletal remains from Late Woodland and Mississippian period sites in North Carolina and Virginia exhibit relatively low long bone fracture rates. As these settlements were occupied by early agriculturalists, these data appear to challenge conventional wisdom concerning the risks associated with farming. To clarify the role of subsistence practices in traumatic injury risk, long bone fracture data from 17 globally dispersed human skeletal samples representing three different subsistence strategies— foraging, floodplain agriculture, intensive agriculture—were compared to test predictions generated from the Ideal Free Distribution Model. According to this model, early agriculture encourages settlement in floodplain environments requiring little labor investment until competition results in higher returns from marginalized areas. These comparisons suggest the risk of traumatic injury did not increase in a linear fashion with the transition to agriculture. In fact, early farming practices appear to be associated with a reduced risk of injury relative to those of foragers. Rather, it was only with agricultural intensification, including built environments and increasing dependence on large animals, that injury rates appear to have increased. These data provide important insights into the agricultural transition and to specific practices and conditions that change the health costs associated with different subsistence strategies.

Wells, Peter (University of Minnesota) [15] Objects, Decoration, and Writing: Dynamics of Communication Media in the Roman Frontier Zone of Temperate Europe

Graves located across the Roman frontier in temperate Europe that contain objects imported from the Roman world provide an ideal context in which to test and refine models for examining the directionality and intensity of cultural exchange across frontiers. Following the Roman conquests west of the Rhine River in the 50s BC and south of the Danube River in 15 BC, a frontier zone at the edge of the Roman Empire was established that was to endure for 500 years. Written sources (Caesar, Tacitus, and others) yield limited information about interaction through merchant ventures and diplomatic missions. But archaeological evidence provides a vast amount of data about the character, scale, and chronology of
interaction between individuals and communities on the two sides of the "border." This paper explores changes in patterns of reception and rejection of Roman cultural elements by native peoples beyond the frontiers with a focus on shifting systems of communication that they employed. The media examined in this ever-changing cross-cultural environment include objects, decorative patterns, and writing - in both Latin and runic scripts.

Wells, Joshua (Indiana University South Bend), Eric Kansa (Open Context), Sarah Kansa (Open Context), Stephen Yerka (University of Tennessee) and David Anderson (University of Tennessee)  

The Digital Index of North American Archaeology (DINAA) project employs linked and open data strategies to make governmentally-produced data about archaeological sites in the United States publicly available for research and outreach purposes, without revealing site coordinates and other sensitive information. DINAA is an Internet index for archaeological concepts of culture histories, site types, diagnostic materials, investigation strategies, and information significance qualities, all structured through Web Ontology Language (OWL) - these in turn are linked to Smithsonian trinomials (also other site names) and obscured geographic locations useful for landscape analyses but not location reidentification. DINAA’s framework and goals are strongly aligned with “Open Data” and “Free and Open-Source Software” (FOSS) movements, so the greatest values and fewest limitations for DINAA’s digital spatial products and linkages are associated with standards and applications that are reusable by the broadest public audience (e.g. OWL, GitHub sharing of ontologies, FOSS GIS compatible data and instructions). The potential of DINAA products and linkages to be reused in outreach, publications, and other scholarly work is derived from these “open” efforts. For researchers, DINAA facilitates the identification, request, and citation of more precise archaeological data from State Historic Preservation Offices (SHPOs) and other secure repository entities.

Werner, William (Syracuse University) [309] Markets, Material Culture, and Mestizaje: Compositional and Archival Investigations of a Museum Accession from 1860s Central Veracruz, Mexico

Since the late nineteenth century, folk pottery produced in the hills and valleys of central Veracruz has attracted the attention of anthropologists and collectors, who offered it as a rare indigenous tradition within a mestizo region dominated by ranching and sugarcane in colonial and postcolonial Mexico. This paper incorporates original archival work and archaeometric analysis to address the social context of a ceramic assemblage submitted to the Smithsonian Institution in the 1860s by the naturalist Carl Christian Sartorius, whose hacienda, El Mirador, was among the most significant in central Veracruz. Archived correspondence reveals that the pottery was likely acquired during a festival market hosted at the hacienda, although the geographic scope of this market is unclear. The chemical composition of the artifacts, determined through neutron activation analysis, was compared to that of modern pottery produced in the small towns surrounding the former hacienda. The results support an interpretation for local manufacture. These findings suggest how archaeometric methods in tandem with archival sources may mutually enhance provenience information of historic collections and elucidate the social dynamics through which the objects circulated prior to their museum accession.

Werness-Rude, Maline (Eastern Connecticut State University) [195] Updating the Chocholá Corpus: New Data Advancing Interpretation

A closely-knit group of Late Classic Maya potters working in the Yucatan Peninsula created a deeply carved set of ceramics in what is now known as the Chocholá style. An examination of a number of examples held in various museum storage spaces helps advance our understanding of these wares. Rarely on display, such vessels provide important information regarding what originally seemed to be a small iconographic subset centered on isolated day sign cartouches. Adding these examples to the corpus indicates that this is a more significant category within the standing body of work than originally thought. What is more, as a group, the day sign cups demonstrate that a particular set of dates were emphasized. When considered in context, it becomes clear that these dates correlate with a series of important events named at Oxlintok, one of the power players in the Puuc region at this time. This evidence adds yet more support to the long-standing idea that Oxlintok acted as the center of a Chocholá manufacturing nexus. Other vessels hitherto ignored in overarching discussions of Chocholá iconography will also be considered, with advances made in our awareness of variation within the different scene categories.

Wernke, Steven (Vanderbilt University) [256] Paradoxes of Place and Power in a Planned Colonial Town in Highland Peru
In the viceroyalty of Peru, the general resettlement of Indians enacted by the Viceroy Francisco de Toledo in the 1570s was among the largest colonial resettlement programs ever enacted, affecting some 1.5 million native Andeans. The program displaced Andean communities into gridded towns (reducciones—"reductions") built around central plazas and churches, and has long been understood as one of the most concrete manifestations of colonial domination. However, the processes by which reducciones were emplaced and constructed remain poorly documented. This paper explores the construction and spatial organization of a large (~30 hectare) and well-preserved reducción in the Colca Valley of southern Peru. Intensive architectural survey and surface collections establish that the reducción was constructed atop a major Late Horizon settlement with elaborate Inka cutstone architecture and a large central trapezoidal plaza. Though the construction of the reducción generally adhered to the prescribed gridded layout, core elements of the prior Inka provincial settlement were integrated into its urban fabric. The central trapezoidal plaza was re-consecrated through the construction of altars and recycled for Christian processions. Overall, a picture emerges of the simultaneous production of dominance and the means for its destabilization through building and dwelling in such hybrid colonial/Andean places.

[S27] Sacrifice, Symbolism, and the Sacred: Redefining Community and Mortuary Ritual at the Shine Site (1Mt6), Montgomery County, Alabama

Recent analysis of David W. Chase's 1963 excavations at the Shine Site (1Mt6) near Montgomery, Alabama, has revealed the presence of a distinct mortuary precinct dating to the Shine I Phase (AD 1200-1400). An examination of interments within this precinct suggests a radical shift in mortuary ritual, ceramic styles, and community architecture took place at the site early in the Shine II Phase (AD 1400-1560). We suggest these changes were part of a physical restructuring of the Shine community and an alteration of local ritual practice and religious traditions resulting from the immigration of distinct Mississippian peoples to Shine (circa AD 1400). In this paper we focus specifically on two burials that appear to have been integral in the redefinition of community relations during the Shine I-Shine II transition. The contexts of these interments suggest that one was part of a ritual terminating the preexisting mortuary regime at Shine, while the second established a new set of mortuary practices at the site.

[286] Shellfish and Paleoenvironmental Reconstruction in Island and Coastal Settings: Variability, Seasonality, and Sampling

In recent years there have been significant methodological advances in sampling and interpreting stable isotope data from shellfish recovered from archaeological sites. In particular, the stable oxygen isotope record in mollusks derived from island and coastal sites reveals trends in shellfish collection intensity, seasonality, paleoenvironment, and broader patterns in local climates. These lines of evidence add a new dimension for interpreting human-environmental interactions. Sampling methods that consider the growth rate of the species in question and the research objectives are essential for accurately interpreting stable oxygen isotope results. This paper will review current techniques in the isotope analysis of shellfish and address future directions for this method.

[181] *Places of Death: New Interpretation of the Development and Utilization of Rock-Cut Tombs in Western Sicily during the Copper and Bronze Ages (circa 3500-900 B.C.).*

This presentation will examine the development and utilization of rock-cut tombs in Western Sicily during the Copper and Bronze Ages (3500-900 B.C.). Although these tombs are often the best indicators of variations in the archaeological record, they have been widely looted or excavated unsystematically and, therefore, largely undervalued in modern archaeological research. Despite the difficulties with the archaeological record, there is still much we can learn about these sites by adopting a progressive methodology not previously applied to them. This project employs spatial landscape approach to analyze the location, utilization, and relationships between rock-cut tomb sites and their physical and socio-cultural landscapes. By integrating data from previous studies and new field surveys, it has been possible to identify a number of key components in tomb placement and utilization over time, including topographic location, tomb visibility, tomb access and the spatial relationships between tombs, settlements, and other archaeological sites. The discovered patterns assert that the prehistoric communities of Western Sicily were making conscious decisions about the positioning of their dead, allowing us to further develop ideas of how tomb use evolved in its relationship to land-use, local/regional identities, and territoriality throughout the course of the Copper and Bronze Ages.

[15] *Modeling Late Nasca Societal Interaction on the South Coast of Peru*

The end of the Early Intermediate Period on the south coast of Peru was a time of unprecedented interregional interaction. People in the Ica and Rio Grande de Nasca drainages engaged in spheres of elite contact, trade and likely intermarriage with groups in the northern Pisco and Chinchu Valleys, southern Acari and possibly Arequipa region, and highland Ayacucho. In the aftermath of Wari colonization during the Middle Horizon, the cultivation of such relationships played a key role in local community politics and the negotiation of colonial relationships. Here we examine the nature of cross-cultural contact at Cocahuisccho, a large Late Nasca settlement. Based on data from excavations and artifact, mortuary, and isotope analysis, we evaluate the evidence for societal interaction between residents of Cocahuisccho and the broader Andean world. Using the model developed by Green and Costion (2013), we suggest that residents of Cocahuisccho were engaged in increasingly broad and mutually influential spheres of interaction with other central Andean groups. The abandonment of Cocahuisccho by the end of the Early Intermediate Period, however, suggests that while some Late Nasca factions forged beneficial ties with Ayacucho people and the emerging Wari state, Cocahuisccho was not among them.

The complex ceramic assemblage of Casas Grandes (or Paquime) was described nearly four decades ago, but little attention was given to the chronology of its development and decline. Recent research and extensive dating have opened new perspectives on this dynamic ceramic assemblage. The implications of these studies extend far beyond ceramics, providing new perspectives on the rise and fall of Casas Grandes.

Whalen, Kathryn (University at Buffalo)

[215] *Avocational Archaeologist Knowledge Project*

Avocational archaeology, in the form of surface survey is a longstanding tradition in Western New York. The goal of the Avocational Archaeologist Knowledge Project is to collect, compile and curate oral histories about the artifact collections of avocational archaeologists in Western New York for the purpose of mitigating the loss of archaeological knowledge caused by hobby field walking and the amassing of archaeological materials by private collectors. The end result of the project is a searchable database of oral histories, photographs of material culture collections, and geographic references for these collections. The motivation is to 1) capture information from hobbyists on archaeological sites in Western New York before it is lost through sale, inheritance or further loss of provenance at the death of the owner, and 2) collect the personal recollections of these avocational archaeologists and their knowledge of our local history. This paper discusses the project methodology, and results as a means of creating a
replicable protocol for other institutions who are interested in similar projects. Examples from our oral history collection will be used to illustrate the value of projects such as these for other public archaeology efforts.

Whallon, Robert (University of Michigan)

Sacred Locales among Hunter-Gatherers
Occasionally, among the myriad named and/or intentionally marked places in hunter-gatherer territories, locales imbued with special, sacred significance are found. The various markings identifying and forming part of these locales are typically numerous, complex, and highly symbolic. The places themselves are typically considered to be beyond significant and meaningful, being powerful, often frightening and dangerous. Often, only certain people, or certain categories of people, are allowed access to these highly sacred places. However, instead of being places to avoid, such sacred locales typically demand regular visitation, physical maintenance, and the periodic performance of ceremonies and rituals. Examples of such places are known both ethnographically and archaeologically, but they are far from universal among hunter-gatherers. The question explored in this paper is when and why places of such extreme sacred character are created and maintained by hunter-gatherers and when and why they are not.

Chair

Whelan, Carly (University of California, Davis)

Long-Distance Acorn Transport in Eastern California
The ethnographic Mono Lake Paiute of Eastern California regularly crossed the Sierra Nevada crest to procure acorns from Yosemite Valley, a total journey of fourteen days. These trips seem economically inefficient and are usually explained as social excursions to visit and trade with the Yosemite Me-Wuk, or as journeys of necessity in years with poor piñon pine nut harvests. An optimal foraging analysis of subsistence options in the Mono Basin reveals that acorn excursions to Yosemite produce more calories than local seed harvesting. This indicates that the long-distance transport of plant foods can be a viable subsistence strategy for hunter-gatherers.

Whitaker, Jason

The San Lorenzo Settlement Cluster: An Investigation into Household Economy in the Mopan River Valley of Western Belize
This paper is a discussion of recent archaeological investigations at the San Lorenzo settlement cluster in the Mopan River Valley of Western Belize. The objective of current research at this ancient hinterland settlement is to better understand household economic organization and integration during the Late and Terminal Classic periods (A.D. 670-890). Households are fundamental units of economic organization in both past and present societies; thus, studying them enables archaeologists to better understand both micro-scale economic activities, and to situate those activities within larger societal contexts.

Archaeological investigations at the San Lorenzo settlement cluster focused on the areas surrounding structure groups SL-22, SL-23, and SL-25. Examination of macroartifacts collected in 2013 shows that the highest artifact densities are in the area south of SL-22. Moreover, excavations in this zone revealed numerous cultural features. Macroartifact densities are significantly lower in the spaces between SL-22 and SL-23, and between SL-22 and SL-25. Preliminary analysis of lithic macroartifacts suggests that the
ancient residents of these structure groups favored local raw materials. Finally, ongoing analysis of the relationship between macro and micro artifacts in the areas investigated will be discussed.

[258] *Calling All Archaeology Careerists: Discussing Archaeology Careers Online*

A careerist is an individual that doggedly pursues professional advancement. This definition aptly describes nearly everyone who has created a successful career in archaeology. Forging a path in archaeology requires a wealth of experiential learning that is amassed throughout an individual's career. In the past, the true mechanics of academic or commercial archaeology were discussed in face-to-face conversations and through academic writings; however, social media has provided a way to expand the discussion to a larger audience of archaeologists working around the world. LinkedIn is a social media outlet for professionals that is frequented by a large number of archaeologists and archaeology students. My research focused on revealing what archaeology professionals of today are talking about and how those topics are relevant to current practice. This paper uses public comments on archaeology related LinkedIn groups to investigate topics relevant to those pursuing a career in archaeology. The insights gained from these conversations illustrate the contrast between professional archaeology as it is practiced and archaeology as it is conceptualized.

White, Andrew (University of Michigan)

[278] *Marriage, Mortality, and Middle Paleolithic Families: Implications of a Model-Based Analysis*

The ratio of old to young adults (the OY ratio) in the Neandertal fossil record is substantially lower than it is for both Upper Paleolithic skeletal samples and relevant ethnographic cases (Caspari R, Lee S-H, 2004, Proc Natl Acad Sci 101:10895-10900). This suggests that Middle Paleolithic populations in Europe experienced a mortality regime unlike that of later hunter-gatherers. An agent-based model is used to: (1) show how the OY ratio is related to fertility and mortality in populations with cultural behaviors and patterns of age-specific mortality like those known ethnographically; (2) examine the effects of imposing a pattern of high adult mortality on culturally "modern" populations; and (3) explore how varying the presence and strength of cultural behaviors and constraints linked to marriage and family size/composition affects demographic viability under such a mortality regime. Viable model populations with OY ratios comparable to that of Neandertals can be produced under conditions of high adult mortality when "families" are relatively large, polygynous groupings whose size is not constrained by the dependency ratio in the same way as it is among ethnographic hunter-gatherers. This result is compared to archaeological and osteological evidence relevant to understanding domestic life during the European Middle Paleolithic.

White, Carolyn (University of Nevada Reno)

[328] *The Archaeology of Burning Man*

Each August, cadres of staff and volunteers begin to construct Black Rock City, located in the Black Rock Desert in northwestern Nevada. Every September, tens of thousands of people travel to it, creating the third largest population center in Nevada. By mid-September, the city is fully dismantled and by October, the playa on which the city lay is scrubbed of evidence of its existence. This city is the locus of the archaeological project that examines the Burning Man festival. As a city on the threshold of destruction and on the verge of creation, archaeological techniques are particularly appropriate for understanding the
created private and public spaces in the city before, during, and after its use. This paper presents findings from five seasons of archaeological survey, mapping, artifact collection, and analysis to interpret the domestic and public space of Black Rock City.

Chair

White, Devin (Oak Ridge National Laboratory) [337] Archaeological Applications of LIDAR

Over the past decade, archaeologists have increasingly embraced airborne and terrestrial laser scanning (LIDAR) as a means to more efficiently and accurately survey landscapes at varying scales, from large regions to individual excavation units. The recent—and spectacular—applications of LIDAR at sites like Caracol, Angamuco, and Angkor Wat have enhanced its popularity, accelerated its integration into our discipline, and in some ways exacerbated existing challenges. The financial and methodological barriers to entry for this technology, and others that can produce 3D point clouds, remains relatively high for archaeologists. Additionally, we are not using the technology to its full extent and, more importantly, are too reliant on outside specialists and organizations who do not fully understand and cannot fully support our research requirements. This needs to change if we truly want to revolutionize how we collect, visualize, and analyze such rich sources of spatial data. This paper will provide information about the technology for the uninitiated, review the state of the practice for archaeology, highlight some applications at the cutting edge to show what is currently possible, and conclude with a few thoughts on how we can begin to take more ownership of how LIDAR is used in our field.

Peopling of the Americas: A Rock Art Perspective

Over a half-century of “dirt” archaeological research has failed to resolve many basic archaeological questions about the peopling of the Americas, suggesting the value of alternative data sources and analytical approaches. What can rock art tell us about the peopling of the Americas? Over the last decade, chronometric and traditional dating techniques have yielded a significant suite of pre-9k YBP North and South American rock art dates. These provide conclusive evidence for widespread rock art production by 10-11k YBP, with multiple examples suggesting circa 15k YBP-aged art. The dates also indicate the existence of at least 7 distinct rock art traditions by 10k YBP, demonstrating that substantial cultural diversity was already in place by Paleoindian times. These data support the developing western North American perspective of very early cultural variability, correcting the over-emphasis on fluted projectile points as monolithic cultural markers that has characterized much traditional Paleoindian research. The values of rock art in this context are straightforward. Unequivocally cultural, exposed/easy to identify, and inferentially rich, as new dating techniques are developed and older ones improved, rock art promises to provide key evidence concerning the oldest problems in New World prehistory.

Environmental Factors for Cancer in Ancestral Puebloans from the Northern Rio Grande

The few cases of cancer reported in ancient human remains around the world suggest modern environmental factors are largely responsible for modern high rates of cancers. Cancer rates in antiquity are, however, probably under-reported and environmental factors that could have caused cancers in antiquity have received little attention from archaeologists. Identification of several cases of cancer in pre-columbian skeletons from the Taos Valley, New Mexico, prompted an on-going examination of possible causes. This region is characterized by high levels of ambient, naturally-occurring radionuclides in bedrock, soils, sediments, and groundwater. Lifestyle decisions of Ancestral Puebloans, such as housing types, construction materials, water and food sources and storage, food processing, and raw material sources, may have increased their exposure to carcinogens. This paper discusses the multiple types of cancer found in the pre-Columbian Southwest and explores potential exposure pathways from natural and lifestyle carcinogen sources. Evidence from this study demonstrates that archaeologists should look more closely at environmental factors that could have resulted in cancer in archaeological populations. In turn, archaeological studies of carcinogen exposure can increase our understanding of
the risks associated with naturally-occurring sources and lifestyle decisions and their implications for modern cancer research, culturally-relevant diagnoses, and treatments.

Whitley, Tamara (Bureau of Land Management) [316] Restoring the Cultural and Natural Landscape at the Piedras Blancas Light Station
The Piedras Blancas Light Station Outstanding Natural Area located on the California Central Coast is being managed for the preservation and public interpretation of the important natural and heritage values found there. This program has included the restoration and reconstruction of the historic light station structures and other features which contribute to the historical context. In addition to these historical elements, the restoration of the natural setting has been an important component of the recovery of the cultural landscape. This presentation illustrates the importance of the natural setting to the interpretation of the cultural landscape.

Medieval Lithuania represents a dynamic time in Europe's history as the last pagan country in Europe prior to the Conversion of Lithuania in 1387 A.D. Lithuania was unique at the time by accepting immigrants of many faiths to their borders. Bone (N=35) and dentin (N=38) collagen samples from the site of Alytus (late 14th through early 18th centuries) offer new insight into the manner in which rural Lithuanians responded to the institution of the Catholic religion, specifically in terms of diet and the adoption of fast days. As of yet, there has been very little stable carbon and nitrogen isotopic analysis undertaken in the Baltic region to investigate diet, and this study aims to address the gap in the data. Analysis of stable isotopic data revealed that the protein portion of the diet mainly reflects consumption of terrestrial non-legumes and very little marine resource consumption, although the use of some freshwater resources is possible (δ13C mean: -20.08, SE: 0.0434; δ15N mean: 10.29, SE: 0.1541). Despite the conversion of the country to Catholicism, individuals at Alytus did not demonstrate δ15N levels consistent with a diet largely reliant on marine resources.

Whitridge, Peter (Memorial University of Newfoundland) [159] Writing History on the Land: Inuksuit As Long-Term Repositories of Cultural Information
Inuit ranged widely across their arctic homeland. Most groups moved seasonally between permanent villages and an array of temporary camps; resources were harvested from large hinterlands surrounding settlements; friends, relatives and trading partners were visited in neighbouring communities; bands periodically pioneered new territories; and individuals were in a perpetual state of exploration and discovery of the world around them. A correlate of the importance of movement was the importance of fixed locations, places amongst which people navigated and which provided cognitive anchors for a dense store of spatial information. In a sparsely occupied landscape learned placenames were an important supplement to more tangible traces of human occupancy, but Inuit also employed the distinctive tactic of erecting simple stone markers or inuksuit at significant locations, such as the inflection in a travel route or the summit of a hill from which a campsite or landmark could be seen. Unlike placenames, which depended on an idiosyncratic stock of cultural knowledge, inuksuit constituted durable material cues that broadcast topographic information in perpetuity to whomever possessed the navigational intelligence to decipher their meaning.

Whittaker, John (Grinnell College), William Bryce (Southwest Archaeology Research Alliance) and Chuck LaRue (Independent Researcher) [182] Conflict among Dispersed Early Agriculturalists: Depictions in Basketmaker II Rock Art
The distinctive Basketmaker II rock art style of the North American northern southwest is well documented (Charles and Cole 2006; Cole 1989; Robins and Hays-Gilpin 2000, Kitchell, 2010). The depiction of atlatls and violence in this rock art has been noted (Farmer 1997), but paid little attention. Recording of atlatl depictions in BMII rock art from 2007-2012 resulted in multiple scenes of violence, typically in the form of duels with two individuals facing each other with darts ready to be propelled, darts in the air, or protruding out of one of the duelists. Many of the panels show the duelists with differing
headdresses. Matson et al. (1988) estimate ca. 440-880 individuals occupying the 800 km² study area on Cedar Mesa of southeast Utah during the Basketmaker II period. Such a low population estimate suggests demographic constraints were not a cause for conflict. Based on headdress style, and assuming headdresses correspond with differing groups, Basketmaker II rock art in southeast Utah illustrates both inter- and intra-group conflict among dispersed groups.

Whittington, Stephen (Wake Forest University)

[83] Cerro Amole and Its Relationship to the Mapa de Teozacoalco
Cerro Amole appears on the Mapa de Teozacoalco, submitted with San Pedro Teozacoalco’s Relación Geográfica to the Spanish Crown in 1580. It is marked by a unique two-tiered structure surmounted by a red cross. Detailed mapping of architecture and artifact locations on Cerro Amole using powerful GPS units during 2013 revealed a dense and extensive site core. It produced data on artifact distributions that define differing functions of various areas and changes in settlement distribution and character through time. Analysis of ceramics recovered from the ground surface supports the interpretation, based on royal genealogies painted on the map, that the capital of the Teozacoalco yuhuitayu was located on Cerro Amole from around 1085 until 1321. This is unexpected, not only because of its short duration, but also because many archaeologists would interpret the site’s monumental architecture, including a ballcourt more than 45 m long, as signaling Classic period (A.D. 300-900) occupation.

[80] Teaching Archaeological Skills through Stewardship: The Wilson Documentation Project
The Wilson Documentation Project was undertaken from 2007-2011 with undergraduate interns and students at the West Chester University of Pennsylvania. The Wilson Collection, orphaned at the university, includes over 1,000 lithic artifacts collected by Harry Wilson from 1890 to 1943, along with Wilson’s log books, scaled field maps, and artifact illustrations. These records are detailed and thorough enough to accurately provenience 100 previously unrecorded sites in southeastern Pennsylvania. The project involved 1) documenting the holdings of the Wilson Collection (maps, letters, illustrations, log book entries, etc.) in OneNote; 2) re-creating assemblages of materials from documentation; 3) producing overlays of historic property maps, U.S.G.S topographic maps and GoogleEarth satellite imagery to provenience assemblages; 4) consulting property records to identify current landowners, 5) conducting site visits to field check, photo-document and record site locations via global position system; and, 6) completing site file forms. Through this project students learned to read maps, perform basic lithics analysis, access municipal records, perform field reconnaissance and interact with landowners. Students involved in the project practiced basic archaeological skills while gaining a profound sense of stewardship and an appreciation for the significance of archaeology for the present and future.

[74] Archaeology Large and Small: The Foundation of Stuart Struver’s Legacy
Introduced to archaeology in the 1950s, Stuart Struver advanced in the 1960s revolutionary ideas including flotation, settlement subsistence, and the organization, scale, and sustainability of archaeological inquiry. Drawing on his family's industrial heritage, Struver formed the Foundation for Illinois Archaeology with a vision of large-scale, integrated, inter/multi-disciplinary research underwritten by a diverse combination of public and private funds. The experiment soon turned into an institution that attracted a critical mass of academic colleagues from the earth, life, and social sciences, a curriculum of coursework ranging from method and theory to natural science and archaeology, and the opportunity presented by public interest in archaeological exploration. The course of development drew Struver from the halls of the academy into the world of grants and contracts and philanthropy, but through it all his goal was to transform how we conduct archaeological research.

[315] A Functional Analysis of "Bend-Break" Artifacts from the Debra L. Friedkin Site, Texas

Use-wear analysis can be used to identify non-formal artifacts as tools that might otherwise be classified as shatter from manufacturing mistakes or post-depositional processes. The radially-fractured and other snap-fractured flakes from the Debra L. Friedkin site in central Texas provides a case in point. Suggested by the number recovered, an initial use-wear survey was conducted. Subsequent experimentation and further microscopic evaluation strongly support the notion that these pieces were indeed multi-function tools that were well used.

[36] Open Geospatial Data: Discussions and Solutions for Publishing Sensitive Rock Art Data Online

The rock art of South Central California includes some of the most intriguing and complex, polychromatic pictographs found worldwide. With the inherent nature of rock art as immovable artifacts fixed within a cultural landscape, spatial analysis is an applicable heuristic for analyzing its networks and relationships to archaeological and environmental contexts. Due to the compelling nature of these sites, destruction from humans has been one of the main problem in site preservation. In the advent of readily available, high-resolution data (e.g. LIDAR) and open access to academic information, locations of these sensitive and vulnerable sites could potentially be accessed even through the GIS analysis outputs. Arguments on the distribution of sensitive data have been predominant within biodiversity concerning dissemination of sensitive/endangered species data and the need to study global species’ populations for public education and decision-making purposes. Similarly, making archaeological data available must not present potential harm the sites. It should instead find a balance between public education and not making the sites vulnerable. We suggest solutions to support open geospatial data for public consumption including micro- and meso-scale presentation, 3D scanning and “blurry” resolutions so that the integrity of these complex pictographs and caves can be preserved.

Wiersema, Juliet (University of Texas, San Antonio)

[120] Ritual Processions and Sacred Space on Moche Fine Ware Vessels

For the Moche, visual evidence for processional activity is preserved on Moche fineline vessels and in monumental architectural remains. Both sources reveal a connection between processions and single-room structures. Fineline scenes, such as the Arraignment of Prisoners, suggest that ritualized activities (presentation, detention, and sacrifice of captives) were anchored and linked by small, free-standing constructions. In the main plazas at Huaca de la Luna and Huaca Cao Viejo, this idea is corroborated by the presence of elaborately decorated rooms which likely served as venues for key events and influenced the direction of movement within the huaca. Further evidence that connects independent structures to processional activity can be found on Moche architectural vessels. These objects, which convey information both two- and three-dimensionally, suggest a central role for small structures in Moche ritual activity. They also reveal a propensity for processional activity that moved in an upward direction.

Wieser, Anna (University of Kansas)

[301] Reassessing the Bronze Age Archaeology of Kandahar Province, Afghanistan

Archaeological research in Afghanistan has largely halted due to armed conflict beginning in 1978. As a result, few publications have focused on archaeology in the country, particularly the southern half, in the past few decades. Several projects have been revitalized in the north, but the south remains blocked off by war and physical risks to researchers. Remote sensing and GIS technologies provide a safe way to maintain the country's presence in archaeological discussions. This poster reviews what is known of Bronze Age occupation of southern Afghanistan, with an emphasis on Kandahar province, and situates it within archaeological developments since 1978. This synthesis provides the background for an ongoing project developing a predictive model of Bronze Age site location and natural resource use in Kandahar Province, Afghanistan.

[163] Unfinished Business: Interpretation of the Fairmont Butte (CA-LAN-298) Archaeological Collection
The archaeological site at Fairmont Butte (CA-LAN-298) has become familiar to many who work in the Western Mojave Desert because of its complexity, substantial rhyolite quarry, deep midden deposits and diverse artifact inventory; however the collection is largely unanalyzed and most of the work remains unpublished. Generated by previous faculty and student excavations in 1989-1996, the collection has recently become the focus of a renewed effort to analyze and interpret the site for the purpose of teaching, student research projects and professional training. In this paper, we present the initial results of the lithic, ground stone, and bead analyses. These new data, in conjunction with previous site interpretations, are evaluated in light of current research in the Western Mojave Desert. Comparisons with other known settlements will be presented to place this occupation chronologically and to provide insight into the development of hunting-gathering focused procurement systems in the region.

Wiewel, Rebecca (University of Arkansas)

Protostrophic Community Formation in the Central Arkansas River Valley: The Use of Compositional Analysis to Identify Regional Interaction

A long-held belief among archaeologists maintains that the so-called Carden Bottoms phase communities of the protostrophic Central Arkansas River Valley contain ceramics from three distinct traditions: local wares produced within the Carden Bottoms locality, imported wares from the Central Mississippi Valley in northeast Arkansas, and imported wares from Caddo communities in the Middle Ouachita region of southwest Arkansas. These beliefs rest on stylistic cues and macroscopic examination of ceramic pastes to discriminate between local and nonlocal wares. This poster presents results of ongoing instrumental neutron activation analysis undertaken to independently assess these assumptions. Ceramic and clay samples from three recently excavated houses at 3YE25 (a Carden Bottoms phase site within the Carden Bottoms locality) containing a cross-section of wares found at the site were analyzed via INAA. Comparative ceramic samples from sites in the Central Mississippi Valley, Middle Ouachita region, and Lower Arkansas River Valley obtained from archaeological collections were also analyzed to determine the provenance of nonlocal wares. Ultimately, this research provides a means of refining our current perceptions of regional dynamics in the Southeast during what appears to be a time of reorganization and community formation.

Wiewel, Adam and Jesse Casana (University of Arkansas) [13]

UAV-based Archaeological Aerial Thermography

Despite a long history of studies that demonstrate the potential of aerial thermography to reveal surface and subsurface cultural features, technological and cost barriers have prevented the widespread application of thermal imaging in archaeology. This paper presents a method for collection of high-resolution thermal imagery using an unmanned aerial vehicle (UAV), as well as a means to efficiently correct and process data using photogrammetric software. To test the method and determine optimal conditions for thermal image collection at sites of different types located in distinct environments, aerial surveys were conducted at a Chaco-period site in northwestern New Mexico; the Mississippian center of Cahokia, Illinois; the Plains Village site of Arzberger, South Dakota; and the Late Bronze Age city of Kalavasos, Cyprus. At most of these sites, our easily replicable methodology produces data that rivals traditional archaeological geophysics in terms of feature visibility, but which can be collected very rapidly, over large areas, with minimal cost and processing requirements.

[252] The Power of Comparison: New Approaches to Ancient Plazas

Among ancient architecture, plazas present various challenges for researchers attempting to understand their roles in societies. Unlike buildings elaborately decorated with iconographic messages, the importance of plazas was as sites for social interaction. Due to the open nature of plazas, they have been
Traditionally viewed as lacking data through which to understand them, recent advances in both scientific methods and theoretical approaches are changing our understanding of plazas. Building on a comparative study of three plazas at the Lowland Classic Maya of Xultún, this paper considers new theoretical approaches to understanding plazas. These approaches are drawn from archaeology, ethnography, ethnohistory, architecture, and town planning. Incorporating modern studies of the use and design of space provides new data for archaeologists that include both human interactions and architectural insights. Studies of ancient plazas can also prove valuable to modern planners, providing the time depth that current architectural studies lack.

[103] *A Bioarchaeological Analysis of Domestic Violence in Post-Imperial Peru*

This paper evaluates changes in violence enacted against women in late prehistoric south-central Peru. As the Wari Empire dissolved ca. AD 1000, populations forged new, regionally based polities no longer supported by a central state. The social, political, and economic unrest of the epoch spurred a myriad of changes: habitations ascended to higher elevations, social identities changed as cranial modification was newly implemented, and traumatic skeletal injuries increased significantly. This study evaluated 68 female crania from three communities in the region. One population dates to the terminal Wari imperial era (AD 880-990) and two others are from a few generations later, during in the fledgling post-imperial era (AD 1000-1250). We observed a dramatic increase in female cranial trauma overall during the post-imperial era, as well as a striking rise in female facial injuries and lethal vault wounds. Barring strong evidence of female hand-to-hand combat, we suggest that the injuries directed towards females were the result of domestic violence, likely spurred to some extent by the social stresses of the post-imperial era.

[209] *Stone Age Archaeology on the Western Head at Knysna, Western Cape, South Africa*

We present previously unreported Stone Age sites near Knysna (Western Cape, South Africa). The sites are located on the Western Head, one of two headlands where the Knysna estuary meets the Indian Ocean. An open-air Acheulean site on the Western Head includes large bifaces, flakes, shatter, and casual cores. At the base of this headland, 3 caves facing into the Knysna strait preserve deposits with characteristic MSA and LSA artifacts. In the southern cave, bone, shell, and prepared core lithic artifacts typical of the MSA are eroding out of a profile with hearth features. Similar artifacts are eroding out beneath a partially cemented aeolean layer in the northern cave. A shell midden (most likely LSA) is exposed in the central cave. Goodwin and Van Riet Lowe (1929) and Deacon (1979) reported Acheulean, MSA, and LSA occurrences near Knysna and on the heads, but these sites were never systematically examined. Additional MSA sites on the Eastern Head are being investigated as part of the current research program. There is a long and rich history of Stone Age occupation in the Knysna region, and the sites presented here show good potential for investigating behavioral evolution through the Middle and Late Pleistocene.

Wilkinson, Tony, Dan Lawrence (Durham University, UK) and Graham Philip (Durham University, UK)

[75] *The Fragile Crescent: Long Term Adjustments to Changing Political and Environmental Changes*

The Fertile Crescent has fostered the growth of domestication as well as the earliest cities. The Fragile Crescent Project has demonstrated that the relationship between settlement and environment is often non-linear, and our research provides compelling evidence for both long-term human sustainability as well as boom and bust cycles. The themes to be tackled for the period ca. 4000-1BC are: 1) strategies of food procurement and production during periods and areas of climatic stress; and 2) the spread of water distribution systems which depend upon changing environmental circumstances and large-scale state dynamics. We conclude that ancient patterns of land use have been partly replicated in the recent past. Particularly relevant to human sustainability have been periods when populations grew in the face of a drying environment, at which time there was a need for societies to adjust their strategies or devolve...
during phases of acute stress. A key message for policy makers is that such conditions might be on the horizon in the Middle East in the near future, because the "perfect storm" of climate drying and population dynamics, together with conflict, may result in changes to human resilience leading to a phase when sustainability will be severely jeopardized.

Wilkinson, Patrick (University of California, Merced)
[139] The Use of Caves in Haitian Vodou
Haitian Vodou is a syncretic religion that combines elements of West African beliefs and indigenous Taino culture overlaid onto a rigid framework of forced Catholicism. One aspect of the religion that has not been investigated is the modern use of caves as a specialized location for various types of rituals, each having a specific purpose. This poster will discuss the use of both ethnographic and archaeological investigative techniques to differentiate the various purposes of cave ceremonies and attempt to determine whether different areas within the caves are associated with specific aspect of the religion, with emphasis on the ephemeral material remains left behind by Vodou practitioners. These material remains include cave iconography, ritual deposits, and ceremonial paraphernalia belonging to both practitioners and adherents.

[288] From Influence to Power: The Path through Chiefdoms to the Emergence of the State
States did not grow directly out of egalitarian societies: between those two social types are found an array of social structures that have come to be called chiefdoms. Whereas some chiefdoms are ranked and organized by status-influence relations, the most complex of them are stratified with organized power structures. In this paper we propose a theory to explain the evolution of social complexity in chiefdoms. Chiefdoms evolve in a series of steps in which old institutions that have failed are displaced by new ones that fail in turn. As a result, the structure evolves from one based on status-influence to one based on coercive power. Our analyses of these changes are based in part on the application of social theory that has been experimentally tested.

Willems, Kimberly (Temple University)
[67] The 3rd Millennium B.C. Mortuary Landscape of Dhank, Oman: Evidence of Transition between the Hafit and Umm an-Nar Period
On the Oman Peninsula, the shift from single or small-order multiple interment tower tombs (Hafit-type cairns; ca. 3100-2700 B.C.) to large, finely built, large-order communal tombs (Umm an-Nar tombs; ca. 2700-2000 B.C.) is not well understood. This "Hafit - Umm an-Nar transition" relies on a simple tomb type dichotomy that does not account for variation in these tomb forms or provide a framework to understand why this change occurred. Recent work at several necropoles near Dhank, Oman has begun to shed light on this transition. This paper will explore the application of a more nuanced classification of the 3rd millennium B.C. tombs in this region and compare this approach with the current simple Hafit/Umm an-Nar dichotomy in order to learn more about the development of the mortuary landscape in this rural
location in northwest Oman. We will present evidence of differential placement on the landscape, intermediate architectural elements, and mortuary rituals unique to a transitional tomb form which we assert is evidence of a gradual process of change between the development of the Hafit and Umm an-Nar tomb forms and that reflects social change during the 3rd millennium B.C.

Colorful Interpretations: Innovative Uses of MAN Analysis in a CRM Setting
Minimum Analytical Nodule (MAN) analysis is an effective method of classifying the lithic raw materials used at a site. A modified version of MAN analysis was applied to the Aught-Six site (5MF3006) in northwestern Colorado. Instead of assigning artifacts to MAN groups en masse as suggested by Larson and Kornfeld (1997), each lithic artifact was assigned to a MAN during the course of the normal lithic analysis. This requires that each artifact be described and coded in an ever growing list of MANs. This modified version of MAN analysis is less time consuming, and removes the necessity of labeling each artifact. The spatial mapping of MANs, and the identification of same-MAN clusters, within temporally discrete components could represent single flint knapping events. These single MAN events highlight lithic reduction strategies at the Aught-Six site. Results from the Aught-Six site suggest that MAN analysis performed one artifact at a time can elucidate trends which help to better understand the lithic technological organization at a site.

Preliminary Excavations at Labouchere Bay, Prince of Wales Island, SE Alaska
Excavations and sea level studies conducted at Labouchere Bay on Prince of Wales Island, Alaska during the summer of 2013 (NSF OPP 1108367) provide new evidence of ancient people’s use of ecologically rich paleoshorelines. The Labouchere Bay site comprises several components including a waterlogged clam bed dating to 10,730 +/-30 cal BP (9490 +/- 40 14C BP, Beta-325353), a raised beach deposit with chipped stone flakes and cores, and several rock shelters with associated shell middens on adjacent terraces. A primary focus of this research is to address people's use of coastal resources in response to rapidly changing sea levels.

Shabe Settlement Dynamics: Archaeological Site Distributions in West Africa during the Transatlantic Slave Trade
This research presents the distribution of archaeological sites in the southern half of the Shabe kingdom, a precolonial African polity in central Bénin. Sites were recorded during field research conducted by the authors in 2012 and 2013. The analysis of artifacts collected from these sites complements geospatial and environmental data to create settlement patterns and reconstruct economic networks in the Shabe kingdom during the 16-19th centuries. Though some goods associated with the transatlantic trade were taken up into Shabe communities soon after European merchants set up along the Bight of Benin, most sites lack artifacts with clear European origins or other evidence of participation in European trade. Instead, Shabe settlement patterns and economies are oriented toward regional, rather than global, networks. It is these regional networks that will be explored.

Williams, Patrick (Chicago Field Museum) and Donna Nash (University of North Carolina - Greensboro)

Wari Burial Practices at Cerros Baul and Mejía
We examine burial practices and human body part interments at Wari affiliated sites on the southern frontier in order to understand how practice represents the expression of identity and affiliation among the diverse occupants of the Baul colony. By comparing the similarities and differences in mortuary practice both within the colonial context and with neighboring and distant Tiwanaku and Wari groups, our goal is to provide insights into the construction of identity at the nexus of state boundaries. We review the types of interments in the colony, characteristics of the deceased, and differential mortuary treatment in distinctive contexts to illuminate the range of mortuary traditions present in the dataset. We then examine this diversity in light of broader Middle Horizon practices.

Williams, Eduardo (COLMICH)

Social Change and Cultural Continuity among Tarascan Potters: A Case Study in Huáncito,
Michoacán, Mexico
How and why do ceramics and their production change through time? Following the perspectives of Dean Arnold, this study tries to answer these questions by tracing social change among potters and changes in the production and distribution of their wares in Huáncito, a Tarascan Indian community located in the Cañada de los Once Pueblos (Michoacán, Mexico). During a period of over 20 years the author has witnessed changes in the families of artisans and the evolution of a ceramic style on a household, community, and regional level. The structural modifications and patterns of cultural continuity discussed in this paper offer a model for ethnographic analogy and archaeological interpretation. This study bridges the gap between archaeology and ethnography, using the analysis of contemporary pottery production and distribution to generate original theoretical explanations for archaeologists working with pre-Hispanic pottery assemblages.

[290] Ethnography and the Interpretation of Ancient Socio-Political Structure on the Plateau
Ethnographies provide vital clues to understanding socio-economic and political structures in more ancient societies. However, ethnographies can also be highly misleading often due to the impacts of Colonial histories. In this paper we examine incongruences between the ethnographic and archaeological records of Plateau groups during the Colonial period with a focus on the Middle Fraser Canyon. We compare the Plateau record to other colonial histories, including the Southeast (Creek and Seminole) and western Arctic (Nunamiut), to develop new frames of reference for interpreting the more ancient archaeological record. In many cases, we recognize inherited social structures that lack strong material manifestations, for example, among the Creeks we recognize social categories for hereditary elite descendant from deities within otherwise more egalitarian social arrangements. Among the Nunamiut of interior Alaska, there are umialgich (or elite boat-owner/whaling captain) statuses reflecting ancestry on the coast. Similarly, Plateau ethnographic sources describe a variety of chiefly and commoner statuses within largely egalitarian groups, hinting that at some point prior to European contact, groups may have indeed been more complexly integrated. We explore the implications of these thoughts for interpretation of the Middle Fraser villages during the late pre-Colonial period.

[318] Chert Provenance Studies from the Gault Site (41BL323), Bell County, Texas
The Gault site (41BL323), located in Bell County (Central Texas), has arguably one of the richest Clovis deposits in North America. The abundance of lithic material thus far recovered makes it important to understand the site in its wider context, specifically raw material procurement and Clovis mobility. In this regard, it is reasonable to suggest that broad patterns in raw material use and mobility can be determined by analytical provenance studies. To test this assumption, and place the Gault site in the context of the wider Texas Paleoindian landscape, two analytical techniques, Laser Ablation – Inductively Coupled Plasma – Mass Spectrometry (LA-ICP-MS) and portable X-Ray Fluorescence (pXRF) have been used to source artifacts to their geologic outcrops. Geochemical variability in chert stems from a complex diagenetic processes, which, when combined with the post-depositional chemical enrichment / depletion in artifacts, provides unique challenges. This poster outlines a new methodological approach for the use of LA-ICP-MS and pXRF in sourcing chert artifacts from the Gault Site, specifically the diagnostic Clovis points, to some of the primary outcrops of the Edwards Plateau. By combining two non-destructive analytical techniques, archaeologists have the potential to study mobility and procurement patterns during the Clovis occupational horizon.

A Reanalysis of Fish Bone from Daisy Cave (SMI-261), San Miguel Island, California: The Evidence for Butchery

The Daisy Cave site (SMI-261) on San Miguel Island, California, dates from ca. 11,500 to 3,000 cal BP, with various occupations throughout the Holocene. Fish were a substantial portion of the faunal assemblage in those strata dating to the late Pleistocene and early Holocene. Edible meat weight estimates indicate that fish contributed approximately 50-65% of the meat during this period. Despite the unusually high concentration of fish bone and the excellent preservation, zero cut marks were identified on the 27,403 fish bones originally analyzed from Daisy Cave. This study aims to test whether the dearth of cut marks is a reflection of current standard analytic techniques. Using results from previous experiments in fish butchery, we reanalyzed approximately 10,000 fish bones from the E-6 column sample, including unidentified fish bones and bone fragments. Although the proportion of cut marks to the overall assemblage remains relatively low, these results highlight the potential bias against butchery evidence introduced by standard analytic techniques. Without a more thorough examination of fish remains, particularly unidentified bones and bone fragments, cut marks will continue to be overlooked in archaeological assemblages.

Understanding Gendered Activities from Surface Collections: An Analysis of the Parker Farm and Carman Cayuga Sites

This research involves studying Iroquois female and male complementary tasks through the use of surface collection materials from two Cayuga sites, Parker Farm and Carman. These economic behaviors, as primarily dictated via societal gender norms, are analyzed in regards to their spatial location in order to showcase economic activity areas and create a broader conception of how the Iroquois utilized their local landscape for daily, seasonal, and yearly projects. Systematic surface collections of lithics, pottery, and bone at both sites are employed to provide intra-site and inter-site comparisons of economic activities. This research has implications for understanding the spatial dynamics of gendered tasks at Iroquois sites and the nature of site occupation.

Deforestation and the Chaco Economy

The rapid growth underlying the Bonito Phase (ca. AD 840 to 1140) in Chaco Canyon, New Mexico, is widely attributed to economic strategies that were unsustainable and led to social instability and population emigration. According to prominent scholars such as Jared Diamond, Pueblo Bonito and other massive Chaco Great Houses were the products of over-exploitation of local resources that created short-term gains but ultimately left the canyon population exposed to unpredictable climate change. In particular, researchers have suggested that deforestation of the canyon for construction and fuel inadvertently destroyed agricultural fields and forced residents into a fragile dependency on long-distance exchange that collapsed during a prolonged drought. In this paper we argue instead that hypothesized deforestation is inconsistent with the empirical archaeological record and long-distance acquisition of timber was not a critical economic factor in canyon abandonment.

Wilmsen, Edwin (University of Texas-Austin)

Pots and Their Clays in interior Southern Africa ca. cal. 200-2012 A.D. as Identified by Microscopic Optical Petrography

Potsherds in Botswana sites dated A.D. 200-1850 appear to have been made in sub-regions other than where they were found. We have employed optical petrography to analyze 304 archaeological sherds and are able to demonstrate the transport of pots within and between these sub-regions and far beyond. To do this, we have collected and analyzed clays from 181 geologic deposits from within interior southern Africa. Examples: 1. Brown-volcanic-glass fabric pots from the Chobe waterveld appear at Bosutswse in the eastern hardveld 530km to the south at AD900-1100; 2. this fabric occurs at Nqoma in the Tsodilo Hills 400km to the west of Chobe before that time, and after a 1000 year hiatus again with migrating Kavango peoples; 2. sherds with a perthitic-texture fabric distinctive of Choma–Kalomo granite in central-southern Zambia are found at Nqoma 600km to the west; 3. Khami style hornblende granite fabric pots from Domboshaba in northeastern Botswana were taken to Tora Nju on the edge of the Makgadikgadi Pans 120km away. Current potters have similar practices. All petrographic identifications were made by David Killick and Dana Drake Rosenstein. Clays were collected by me and Phenyo Thebe; potter interviews were led by Anne Griffiths.

Wilshusen, Richard (History Colorado)
Early Pueblo Great House Communities and Their Leaders: Tools for Identifying the Social Networks of Leadership in Mesa Verde and Chaco

The last decade of research has revealed that the earliest "great houses" are found not in the Chaco region, but instead within the centers of ninth century Mesa Verde villages. The communities focused on these first great houses prove to be politically, economically, and demographically unstable; and by the tenth century significant population declines in the Mesa Verde region can be linked to concurrent demographic growth in the Chaco region and the emergence of the first Chacoan great houses. This second great house experiment appears to have been built on a hybrid model of two earlier patterns of community organization and leadership. Building on a proposal coauthored with Scott Ortman and Ann Phillips, I use additional evidence in this paper to demonstrate how to identify tenth century communities and community leaders in the Chaco region. Better-defined social networks that linked tenth century great house community heads may allowed for a more sustainable model of serial leadership than was the case in the ninth century Mesa Verde villages.

Conflict and Community: An Architectural Analysis of a Catastrophically Burned Mississippian Village in West-Central Illinois

The early 13th century A.D. witnessed the intensification of inter-group violence throughout large portions of the Middle Mississippian region and adjacent areas of midwestern and southeastern North America. Changes in the scale and intensity of conflict led to the nucleation of previously dispersed populations into fortified settlements. Ongoing architectural analysis of the catastrophically burned Orendorf site in the Central Illinois River Valley of west-central Illinois provides the opportunity to investigate this dynamic process. Our research has revealed that the establishment of compact living arrangements within the Orendorf village entailed the negotiation of new social institutions and relationships as well as the novel incorporation of traditional organizational conventions.

Wilson, Charles (Southwestern Baptist Theological Seminary)

Artifacts and Architecture of Structure 6, Wolf Village, Goshen, Utah

Structure 6 at Wolf Village, Goshen, Utah, is a surface structure with characteristics that conform to and depart from normal Fremont houses. Evidence of household activities is seen in manos, charred Indian rice grass lemmas recovered from the hearth area, and a high frequency of bowl sherds. But Structure 6 also has several unusual characteristics that place it outside the expectations of normal houses. These characteristics include Structure 6’s surface architecture (as opposed to pithouse architecture), a ventilation tunnel (previously unattested with surface buildings), a thick midden deposited over the structure collapse, a number of deer mandibles deposited in the ventilation tunnel (likely deposited at the time of abandonment), and eight clay figurines and figurine fragments found in and around the structure, possibly deposited in a termination ritual. Examining the artifacts and architecture of Structure 6 together suggests that what sets this adobe-walled building and its contents apart most is not the evidence of how the building was used, but how the Fremont walked away from it. Structure 6 was probably home to an individual of special status, and possibly served as a communal integrative facility.

Mound Construction and the Built Landscape: Results of the NSF-REU Research on Earthworks at Angel Mounds, Indiana

Our NSF-sponsored REU focused on built landscapes, particularly earthworks, at Angel Mounds, a Mississippian town in southwestern Indiana. Results offer insights about use, failure, erosion and rebuilding of Mounds A and F, as well as seismic activity in the midcontinent. Closely spaced, solid-earth cores collected from Mound A in 2013 (and earlier research) show that its “upper platform” was built around AD 1080-1100 by stacking >60,000 m3 of overturned turf blocks and basket loads within 10 years. Subsequently, Mound A underwent significant slumping and sheet-washing before the “lower platform” was constructed. The lower platform was expanded at least twice, but also underwent major episodes of erosion, slumping and repairs. Mound F was extensively excavated in 1939-42 and 1964-65 and includes two sequentially buried platforms (“Inner” and “Primary”). The only intact profile left after 1965 was reexamined in 2013 and revealed details about the Inner Mound and human activity on the premound surface. Additionally, liquefied sand was likely injected into the Inner Mound fill during a
significant, post-AD 1100 earthquake. Forthcoming OSL/AMS ages from both mounds will improve the chronology and our understanding of premound structures and cultural activity, initial mound construction timing, and seismic events at the site.

Winburn, Amanda, Larisa DeSantis (Vanderbilt University) and Tiffiny Tung (Vanderbilt University) [103] 3D Dental Microwear Analysis of Maya Elites from Cancuén, Guatemala

Microscopic wear patterns on teeth are commonly used by paleontologists to analyze diets of animals; their application in bioarchaeological studies has been less frequent. This study uses dental microwear texture analysis (DMTA) to quantify microwear in three dimensions on the molar teeth of Maya elites from the Classic site of Cancuén (Petén, Guatemala), who died when the city was attacked and defeated in 799 A.D. Dental replicas of a polyvinylsiloxane impression material were prepared and hardened with an epoxy resin and hardener; these replicas were scanned in three dimensions in four fields of view and analyzed with SSFA software to characterize the tooth surfaces in terms of complexity, scale of maximum complexity, anisotropy, heterogeneity, and textural fill volume. Microwear provides insight into ingestive behavior during the final weeks of life by distinguishing between ingestion of hard, soft, and tough objects; these results demonstrate the usefulness of this method in understanding aspects of diet shortly before death. Preliminary results suggest that Maya elites were consuming or processing brittle foods. Further, we discuss how using dental microwear analysis in conjunction with carbon and nitrogen stable isotope analysis of bone and teeth can provide a more comprehensive understanding of diet across the life-course.

Winchell, Frank [58] The Butana Group and Its Independence from the Central Nile Valley and Predynastic Egypt in the 4th Millennium BC: The Rise of the Eritrean-Sudanese Lowland Culture

In the far reaches of the eastern Sahel in Sudan a ceramic-bearing culture group, known as the Butana Group, arises from a more generalized and widespread Late Mesolithic tradition associated with the Central Nile Valley and northern Africa at the end of the 5th millennium BC. Within a span of some several hundred years, the Butana Group emerges as a distinct culture from the Central Nile Valley at the same time the Egyptian Predynastic cultures begin to dominate the Lower Nile Valley and into Nubia. In contrast to Nubia and its interaction with ancient Egypt, the Butana Group develops into an independent culture, more oriented to the Horn of Africa, may have developed incipient cultivation of native African cereals such as sorghum, and is essentially the formative development of a Eritrean-Sudanese Lowland culture by the first half of the 4th millennium BC. This Eritrean-Sudanese Lowland culture may have been part of the region known to the Dynastic Egyptians as the land of Punt.

Winchell-Sweeney, Susan [211] see Lothrop, Jonathan

The nearly contiguous 46-acre footprint of the Luke Solar project area housed a shallowly stratified middle and late Archaic archaeological record associated with a laterally complex mosaic of distal bajada alluvial fan deposits. One of the primary objectives of the geoarchaeological analysis was placing this important archaeological record into a time-stratigraphic framework. The complex nature inherent to alluvial fan environments, however, makes correlation across space difficult if not impossible without some form of independent age control. One hundred and twenty radiocarbon dates from geologic and cultural contexts along with the detailed description over 200 profiles, exposed in mechanically excavated trenches, allowed us to place site deposits into five major geologic units. The chronostratigraphic model indicates site occupations were contemporaneous with a major period of fan deposition between 4500-4000 14C yr BP and with multiple fan aggradational episodes dated between 2900-1300 14C yr BP. Regionally, the periods of active fan deposition at Luke Solar correlate with other dated alluvial fan and paleoflood deposits in the Southwest suggesting climate change as a major driving mechanism for both geomorphic and prehistoric cultural shifts.

Using GIS and GIS 3D to Reveal the Cultural and Natural Landscapes of Ancient Maya Salt Works with Wooden Buildings Submerged and Preserved by Sea-Level Rise

In this paper, we describe the methods we used to transform and integrate data collected at over 100 inundated archaeological sites in Paynes Creek National Park, Belize into a modern geographic information system. The Paynes Creek sites were salt works where brine was evaporated in clay pots over fires, an activity which took place indoors on a massive scale. The wooden buildings were perfectly preserved in mangrove peat below the sea floor. Our data include geographic locations and attributes for over 4,000 preserved wooden posts, associated artifacts, core samples, and the results of sonar mapping in selected areas. Data are based on underwater survey, mapping, and excavation. The locations of wooden posts were mapped with a laser total station and processed in a traditional GIS environment. Point features representing wooden posts were converted to raster area features and extruded above existing bay floor levels in a 3D GIS environment. Post diameters were subsequently used to determine function and reconstruct structures as they might have appeared during the Late Classic period (A.D. 600-900). The methods we developed can be adapted to solve a variety of archaeological problems and provide 3D renderings of relic cultural landscapes.

Mesa Verde’s Great Drought, Faunal Remains and Great Kivas

There is sufficient evidence that the Great Drought (A.D. 1276-1299) in the Mesa Verde region of the American Southwest affected the lifestyles of Ancestral Puebloan people. However, the impact of the drought on Ancestral Pueblo religious ceremonies has received less attention. We examined the faunal assemblages of two great kivas in the Goodman Point Pueblo Unit in southwest Colorado. The faunal assemblages we compared were excavated from a great kiva (5MT16805) decommissioned before the drought (1260s) and a great kiva (5MT604) abandoned toward the end of the drought (1280s). Comparative analyses of taxonomic abundance and species richness of the two great kiva assemblages demonstrated changes from a turkey dominated, low species richness to a cottontail dominated, higher species richness. Our results suggest that the people of Goodman Point switched from using turkey to rabbit in ceremonial contexts in response to the Great Drought. Ethnographic evidence leads us to believe that this transition to rabbit use in great kiva ceremonies has been maintained until historical times by some Pueblo descendants.

Implementing Geoarchaeological Methods to Explore Site Formation Processes of Pastoralist Occupations in Eurasia

Throughout Eurasia, ephemeral habitation sites occupied by pastoralists have notoriously eluded archaeological detection. This paper aims to distinguish cultural versus natural agents of deposition and evaluate site stratigraphy. Geoarchaeological methods are implemented to understand the relationships between climate, sedimentation, pedogenesis, and anthropogenic activity. Geochemical signatures and site formation processes are analyzed in the mountains of Uzbekistan and Kazakhstan to determine if recovered data represent in situ pastoralist occupations.

Phylogenetic Analysis of the Arctic Small Tool tradition: Implications for History and Cultural Macroevolution in the North

Phylogenetic analysis in archaeology offers scholars the tools for rigorous examination of hypotheses concerning cultural evolutionary process ranging from the modern era back to ancient times. Addressing evolutionary questions may also provide insight into the history of particular groups of people. The Arctic Small Tool tradition (ASTt) appeared in the western North American Arctic shortly after ca. 5000 B.P. and...
is considered to be associated with a human group broadly identified as the “Paleoeskimo” people, who eventually moved into the Canadian Arctic and Greenland. Significant debate exists regarding the origin of the ASTt (whether Siberia, Primorye, or Southwest Alaska?), the nature of ASTt variability, and its associated evolution. This paper presents a phylogenetic analysis of cultural macroevolution associated with the ASTt. We address a range of hypotheses regarding cultural origins, divergence, and cultural evolutionary process. Artifact and feature data are derived from a range of sites potentially including those associated with the Malyshovo Culture of Primorye, Bel’kachins culture of eastern Siberia, Denbigh Flint Complex of NW Alaska, Brooks Gravels, Russell Creek, and Margaret Bay phases in SW Alaska, Pre-Dorset in the Canadian Arctic, and the Independence I and Saqqaq phases of Greenland and the Canadian High Arctic.

Winter-Livneh, Rona, Tal Svoray (Prof.) and Isaac Gilead (Prof.) [65] Shape Reproducibility of Prehistoric Dwellings in the Southern Levant (Israel)

Different attributes of structure such as shape, size, material and decoration have significance beyond their immediate function. They provide invaluable information about social aspects of past societies, as well as evidence concerning modes of adaptation to environments, changes in population size, technology and subsistence economy. While attributes such as size can be measured, and therefore objectively compared between structures, the comparison of shapes between structures is based on subjective observations. This presentation introduce a new method, Shape Reproducibility (SR), based on objective computerized procedure for analyzing the similarity between shapes of ancient structures. Matlab and GIS platforms are used for this analysis. Applying this method to settlement data of the Chalcolithic period demonstrate that in the main cultural Chalcolithic entity, the Ghassulian, the architecture of different sites could not be distinguished from one site to the other. In addition, we demonstrate that the architecture of the Chalcolithic sites in the Golan Heights is homogeneous and significantly differs from other Chalcolithic sites, while Ghassulian intra-site variability is higher. In comparison with Arad, however, this variability is relatively low and limited. These results suggest that status differentiation or hierarchical social organization cannot be indicated from Ghassulian architecture.

Winter-Livneh, Rona [117] see Hulse, Eva

Winzenz, Karon (University of Wisconsin-Green Bay) [164] The Painted Sky Bands of the Maya and the Textile Domain

The skybands (celestial bands) on San Bartolo’s Late Formative murals provide the framework for an examination of those painted on Late Classic vases. This study supports the hypothesis that processes and structures associated with textile techniques were the likely source for both the template and specific symbols found in these registers. Although humidity in the Maya region has destroyed all but a small sampling, weaving and fiber technologies were likely the primary carriers of symbols used to express core religious concepts of the early Maya before the transition to sedentary life. The conceptual and iconic relationships between celestial bands and the technologies of weaving, lashing, knotting, and bundling created a symbolic vocabulary in which a template from the textile domain was transferred to the cosmological domain. Moreover, these techniques were practiced by all levels of society and their symbolism would have been universally understood. Today, the use of weaving and spinning metaphors for cosmic creation continues among more traditional descendants.

Wismer-Lanoë, Meredith (University of Iowa) [320] Subsistence Practices in the Tallgrass Prairie: A Re-analysis of the Rainbow Site (13PM91) Faunal Assemblage

The Rainbow site (13PM91) is a multicomponent Woodland site located in northwest Iowa, within the tallgrass prairie of the Midcontinent. Salvage excavations conducted by the Luther College Archaeological Research Center in 1978, and later reports by the Iowa Office of the State Archaeologist, revealed the significance of the site for understanding human-environmental interactions within the Woodland period. Today the site remains one of few examples within the region for Woodland period habitation sites containing substantial faunal remains. The current study is a re-analysis of the faunal assemblage using modern quantification methods. In addition to diet breadth analyses, an emphasis is
placed on reconstructing subsistence practices using skeletal part frequencies, degree of fragmentation and burning, as well as presence of cut-marks. Taphonomic damage is recorded and used to evaluate the potential for non-anthropogenic impacts on the assemblage. The Rainbow site (13PM91) offers a significant source of information regarding Woodland subsistence practices and is also valuable for understanding the long term subsistence trends that eventually resulted in the adoption of large-scale agriculture in the region.

Witt, David (SUNY Buffalo) [56] The Study of Borders and Frontiers and Their Role in Chacoan Hegemony

The study of borders, boundaries, and frontiers has been approached by archaeologists and other social scientists in various regions of the world, including the American Southwest. These terms do not indicate mere lines in the ground, but zones of interaction through which people, goods, influence, and even control, extend in both directions to various degrees. This interpretation allows for the incorporation of concepts such as hegemony, which is the predominant influence in ideological, political, military, and/or economic matters exercised by one society over another. Addressing these concerns, this paper will present a history of the theory and methodology used to study such phenomena, as well as provide examples of more modern, theoretically advanced approaches. Finally, the expansion of the Chacoan system will be broadly discussed in this light, and examples of hegemonic growth will be highlighted, while providing a basis for other papers in this panel.

Wix, Elizabeth (The University of Alabama) [272] Mississippian Kinship and the Organization of Koger’s Island Cemetery Rows

The assumption that Mississippian societies were exogamous and matrilineal has not been tested. This pattern of kin group organization may be examined archaeologically through biodistance studies of cranial and dental remains. This paper focuses on the Mississippian cemetery of Koger’s Island to determine if average genetic homogeneity within cemetery rows at Koger’s Island is greater than the overall genetic homogeneity of the population, and further, if there is greater homogeneity among females within rows than males. If confirmed, it may be inferred that kin groups were both matrilineal and exogamous. Confirming matrilineality and exogamy within this cemetery population would contribute to a growing awareness that forms of kin groups were not uniform across the Mississippian Southeast. The Koger’s Island burials have been compared in terms of grave goods, age, sex, and trauma, but no prior biodistance study has been conducted to determine biological kin organization within the cemetery. Cluster analysis is used to examine overall patterning within a Gower’s matrix. Clusters of individuals are predicted to fall into distinct spatial groups, indicating that individuals were interred with biological kin. Also, females within clusters are predicted to have greater homogeneity than males indicating the exogamous matrilineality expected for this Mississippian group.

Woldekiros, Helina (Washington University in Saint Louis) [205] The Role of Small-Scale Border Towns in the Development of Complex Societies in the Ethiopian Highlands

The Aksumite (150 C.E.-C.E. 900) and medieval periods were important for the development of complex societies in northern Ethiopia. Historical data and exotic goods during these two periods suggest that provisioning of highland towns and cities with lowland resources such as gold, salt, and obsidian was an important component of the economy and of increasing complexity. However, the lowland communities taking part in this interaction have never been identified or explored. This archaeological study provides artifactual and landscape-based evidence that indicates that the small-scale border towns of Agula and De’sia located between these two zones played a significant role in facilitating access to lowland resources. Archaeological survey and settlement analysis indicate that small towns were strategically located near the least-costly path to lowland resources. Zooarchaeological and paleoethnobotanical evidence suggest that these towns were not resource-rich themselves, but that they provided institutional structure and logistical support for trading routes.
Wolf, Marc (GWE Corp.)

[191] Ancient Maya Frontiers in the Verapaz Departments of Guatemala

The archaeological sites within the Verapaz department of Guatemala exhibit an intriguing mixture of lowland and highland Maya architectural styles. The region marks the liminal zone between the traditional Maya lowlands that stretch into and beyond Guatemala’s Peten and the uplands that reach toward and past modern Guatemala City and Antigua. The site of Cancuen—located along the folds of the winding Pasion River—displays a markedly lowland style of construction that stands in glaring contrast to the theorized highland stylings of sites like Raxruha Viejo, Siltzul, La Lima, and Cebol that lie a scant 12 km towards the foothills west of the Cancuen epicenter. These differences are supported by a variety of data aside from the settlement patterning of individual sites—ceramic assemblages, specialized architecture (such as palace, ball-court, shrine or temple complexes), and other conspicuous cultural indexes (i.e. stone monumentation and other dedicatory caching rituals) combine to reinforce the unique identities that collide in this frontier zone. The most obvious demarcations and hybridizations of these traditions are visible in the buildings and spatial relationships between architectural elements when comparing different sites from the region.

Wolff, Nicholas (Boston University Department of Archaeology) and Matthew Pisci telli (University of Illinois at Chicago)

[146] Reading between the Lines: Micro-Stratigraphic Analysis of Ceremonial Contexts at the Late Archaic Site of Huaricanga, Peru

This paper presents the results of geoarchaeological analysis conducted in conjunction with the recent excavation of small-scale ceremonial structures at the Late Archaic (3,000-1,800 BC) site of Huaricanga in the Fortaleza Valley, Peru. To date, little is known about the specifics of ritual behavior in the context of these distinctive architectural features. In an effort to rectify this gap in our knowledge, intact block samples were collected from sequences of superimposed floors and fills within these structures and subjected to micro-stratigraphic and micromorphological examination. The initial goal of this study is to elucidate modes of depositional practice in floor construction and fill emplacement, with particular emphasis on material selection and treatment, the timing and periodicity of depositional events, and any evidence for residue or alteration of floor surfaces that might shed light on the kinds of activities which took place within these buildings. These results in turn shed light on specific ritual practices, distinctive histories of use, and variability in the form or make-up of the structures themselves.

Wolff, Christopher (SUNY-Plattsburgh)

[325] Changing Times or Time for a Change? Dorset Technological Practices at the Stock Cove Site, Newfoundland

The Stock Cove Site of Eastern Newfoundland is a large, stratified, multi-component site. Evidence from the site suggests the largest and most intense occupation was by Dorset Paleoeskimos; however, artifacts representing antecedent groups, Maritime Archaic and Groswater Paleoeskimos, and subsequent groups, Ancestral and Historic Beothuk peoples, have been recovered in stratigraphic sequence with hints of some chronological overlap. To have such an opportunity to study historical and environmental processes at a single location is rare in Newfoundland, as it is in most of the Eastern Subarctic and Arctic, and provides us with a unique opportunity to understand cultural interaction and continuity. Within that guiding framework and context, the research presented here will focus on Dorset technological practice utilizing a historical perspective to assess the development of technological variation through time. We demonstrate that the depth of the Dorset deposits permits us to assess tool production through a long-term lens and document changes in practice and their relationship to variations in environmental and cultural conditions.

[84] Moving Beyond ‘The Local Range’: Statistical Approaches to Interpreting Herd Management Strategies through Stable Strontium Isotopes at Neolithic Çatalhöyük (Turkey)

Despite Çatalhöyük’s isolation as the only permanent settlement in central Turkey’s Konya Plain throughout its Neolithic occupation (9,500-7,500 BP), paleoenvironmental reconstructions and material
cultural evidence indicate that the world of Çatalhöyük regularly extended well beyond the site's boundaries. An important aspect of that world is the landscape regularly visited by herders and their domestic flock (Henton 2012; Bogaard, et al. 2013). Stable strontium isotopic values from animal teeth reflect patterns of landscape use by herds; analyses of these values allow identification of regularly frequented areas. Stable strontium isotopic ratios (87Sr/86Sr) have been analyzed for thirteen sheep molars from chronologically and spatially diverse levels of Çatalhöyük seven previously published (Bogaard, et al. 2013) along with six new samples. Here I compare all of the Çatalhöyük sheep tooth specimens’ 87/86Sr ratios to landscape 87/86Sr ratios to investigate trends over time in landscape use and herd mobility. I also briefly explore interpreting stable strontium isotopic analyses using maximum likelihood, a statistical technique that involves using datasets to identify parameters that best fit the data at hand. Using the Çatalhöyük isotopic ratios, I estimate the amount of time each sheep spent in more distant landscape zones and evaluate different herding system models for the site.

[206] Zooarchaeology and Vertebrate Taphonomy of Contemporary Goat Ranching at Puesto Toscal, Western Argentina

The puesteros of west, central Argentina are traditional ranchers and pastoralists who live in the plains and range up into the Andes. In western Mendoza province, puesteros ranch in areas that cross several culture continua and physical environmental gradients, such as varying degrees of interaction with urban economies and differences in residential mobility related to elevation and livestock range condition. Puestero herding lifeways vary from seasonal transhumance (to take advantage of shifting plant phenology from low to high elevation) to sedentary small ranches with large ranges in order to provide opportunities for mobility of grazing goat and cattle herds. Puesto Toscal has been occupied by sedentary puesteros for forty years, and has a series of primary and secondary midden deposits surrounding the ranch house. Analysis of faunal remains from the middens provides a record of puestero ranching and cultural adaptation.

Wolynec, Renata (Edinboro University of Pennsylvania)

[88] The Fall and Rise of Zahi Hawass

Zahi Hawass, the Egyptian archaeologist, is close to a rock-star celebrity. His name is well known by the public in many countries outside of Egypt. This paper explores English speaking press coverage of Zahi Hawass since the Arab Spring demonstrations in Egypt in 2011. This press coverage focused on how he was perceived by the demonstrators and government, what Hawass thought of himself, how he was valued by the professional archaeological community, and more.

[280] Characterizing Climate in Central Texas during the Calf Creek Period Using Speleothem Proxies

The Calf Creek horizon (c.a. 6 kya) occurs throughout the Southern Plains and is a temporal marker. The exact timing of the period, however, is imprecisely constrained, and it is unclear whether the Calf Creek culture persisted under dry conditions or flourished during a brief wet interval. To help address these uncertainties, we present a Holocene climate reconstruction from a central Texas cave deposit (speleothem). We find that speleothem growth was fastest (50 IJm/yr) from 6.5 to 5.5 kya. During this interval, carbon isotope values and Mg and Sr concentrations increase and peak at 6.0 kya, then decrease to a low by 5.5 kya. Faster speleothem growth rates and lower carbon isotope values and Mg and Sr concentrations are interpreted to reflect wetter conditions. These results suggest that it was wet from 6.5 to 5.5 kya relative to the rest of the mid to late Holocene. Within this interval, however, conditions were driest at 6.0 kya. If the Calf Creek period was centered at 6.0 kya, then it is likely that the climate during this period was at the driest point of an interval that was wet relative to the rest of the mid to late Holocene.

Charity on the Fringes of the Medieval World: Skriðuklaustur, A Late Medieval Priory-Hospital in Eastern Iceland

The aim of this study is to understand how the medieval Western European model for the charitable monastic practice of the care for the poor, sick and infirm, was adopted in Iceland at Skriðuklaustur, a late medieval Augustinian monastery. The research was conducted by utilizing a combination of archaeological and historical cross-cultural research supported by the social theory of structuration in order to create a context in which to address the issues and questions concerning the archaeological and architectural features of Skriðuklaustur that have been used to ascribe the role and function of the monastery within medieval Icelandic society.

Wood, W

The Lincoln Area Office and the Upper Missouri River Basin

Lincoln, Nebraska was chosen as the headquarters for the Missouri River Basin Surveys because of its central location and the offer of office space at the University of Nebraska. Between its onset in July 1946 and mid-1969, archaeologists from that office carried out excavations throughout the Missouri Basin, cooperating with ten state and local entities as they did so. Nearly 100 major excavations were conducted in sites along the Missouri River, and numerous others on its tributaries. The results of this work provided the foundation for our present understanding of the prehistory of the Northern Great Plains.

Wood, Nicholas (University of Mississippi)

A Sociopolitical Perspective of Hollywood Mounds (22TU500)

The Hollywood Mound site is a 15th century multi-mound and village center located in the Yazoo basin. The site is dominated by Mound A, a large platform mound located at the center of the site. To the east lie four boundary mounds, while it has been established that the boundary mounds were constructed prior to Mound A, the contemporaneity of the mounds is unclear.

This research examined this question of contemporaneity by examining one boundary mound (BC) through excavation. Through a combination of radiocarbon dating, pottery analysis, and stratigraphic data, I address the occupation of a boundary mound to better understand the relationship between Mound A and the boundary mounds.

Woodfield, Brent (University of Louisiana at Lafayette)

Salinas de los Nueve Cerros: Production and Exchange at the Nexus of the Maya Highlands, Southern Lowlands, and Chiapas

Salinas de los Nueve Cerros was a major economic hub at the borderlands where three different regions of the Maya world connected—the northern highlands, the southern lowlands, and Chiapas. Residents of the city exploited a large salt source in the site core during its over two millenia of occupation, exporting the finished product far into each of these regions. As a result, it is an ideal site to examine interregional communication and exchange from the rise of the first Maya cities in the Middle Preclassic period (1000-250 B.C.) through the northern highland florescence during the Early Postclassic (A.D. 900-1200).

Obsidian Sequin Manufacture at La Sierra de las Navajas, Pachuca, Mexico

From A.D. 200 to 400, craftsmen at La Sierra de las Navajas were producing quantities of small circular sequins made from segmented obsidian prismatic blades. Finished sequins have been found far from the source at Teotihuacan, including sites in the Maya area, and they appear to be part of political relations between Teotihuacan and Kaminaljuyú, as well as Tikal and Izapa. A prehispanic bead-making workshop at the Pachuca source reveals the process of manufacture, including a unique perforating technique that has only recently been replicated by the authors. Completed specimens recovered from other sites in the area of Teotihuacan suggest these may have been associated with high-status individuals, possibly related with a warrior class.

Woods, Aaron (University of Nevada, Las Vegas)

Abandonment, Relocation, and Reorganization: The Harris Site in the Late A.D. 900s

Recent investigations at the Harris Site have determined that its Late Pithouse period (AD 550-1000) occupation ended in the late AD 900s. In the Mimbres region, the end of the Late Pithouse period is marked by important changes in settlement that are defined by a general abandonment of pithouses and
the development of above-ground pueblos. The succeeding Classic Period (AD 1000-1130) settlement pattern reflects a strategy of placing pueblos directly on top of Late Pithouse period villages. The Harris site is one of the few exceptions to this, as no Mimbres Classic Pueblo was ever built on top of it. The nearest Classic Period pueblos to the Harris Site are the Stewart and Ewell Ranch pueblos. The lack of a Classic Period pueblo directly on top of the Harris Site and the close proximity of Stewart and Ewell Ranch pueblos raise questions regarding the abandonment of the Harris site, community relocation and reorganization, site location preferences, and land tenure. Results of archaeological investigations at Stewart and Ewell Ranch Pueblos are presented and used to make inferences regarding the post-Pithouse period occupation of the Harris Site and the surrounding area.

Woods, Julie (University of Massachusetts, Amherst) [328] *From Nichewaug to Petersham: Evolving Land Use and Cultural Landscapes in a New England Forest*

Nichewaug was a densely forested land of many rivers, ponds and lakes, located in the rolling hills of Central Massachusetts. This area falls within the traditional territory of the Nipmuc people. As the Massachusetts colony expanded westward, settlers were encouraged to turn the forests into farms and develop new local and regional industries thus improving "unimproved" lands, controlling waterways, and threatening thousands of years of sustainable land use. This paper shares the story of changes seen in the forest ecology and cultural landscapes at Harvard Forest in Petersham, Massachusetts through the 19th century as seen through the lens of archaeology.

Woollett, Jim (Université Laval), Céline Dupont-Hébert (Université Laval, Centre d'études nordiques), Guðrún Alda Gisladóttir (Fornleifastofnun Íslands), Úggi Ævarsson (Minjavörður Suðurlands) and Natasha Roy (Université Laval, Centre d'études nordiques) [29] *A Boom and then a Bust in a Northern Icelandic Community: The Svalbarð Estate Circa 1200 to 1477 A.D.*

Through five seasons of fieldwork, the Archaeology of Settlement and Abandonment of Svalbarð project has sought to examine settlement patterns and economic practices in the community associated with the estate of Svalbarð (Þistilfjörður, north-east Iceland), over a period of approximately 1000 years. Work to date points to the 13th to 15th centuries as a period of particularly important social and economic change. Notably, the Svalbarð church farm appears to have been expanded while some of its neighbours, poor and not so poor, were enclosed or abandoned. At the same time, sheep herding, fishing and marine hunting activities were all of increasing importance across the Svalbarð estate community. Results of ongoing archaeological research at the sites of Svalbarð and Hjálmarsvík will be presented to contrast economic trends at neighbouring farms after circa. 1200 AD. Long-term trends in settlement will be discussed through the results of a complete survey of auxiliary farms, shielings and other installations. While the influence of climate change processes on tenancy and land use patterns is clear in this study, it also seems likely that the survival of individual farms had as much to with their role within community-scale social and economic networks as with local-scale ecological viability.

Wopschall, Kayla (University of Washington) [223] *Pygmy Hippos of Cyprus: An Interdisciplinary Approach to Understanding Late Pleistocene Maganfauna Extinctions*

The cause for Late Pleistocene megafaunal extinctions is hotly debated, with arguably two main competing contributors- humans and climate change. Within this debate, island extinction events are frequently used as the foundation for understanding the mechanisms of their continental counterparts. While islands make for a great ‘natural laboratory’ for studying extinctions, many of these events are Holocene in age; focus on avian species, not mammals; and/or have poor chronological control, complicating correlation between the mechanisms for extinctions in these island examples and large mammals in the Late Pleistocene. Here we evaluate the potential impacts on the extinction of a large endemic mammal, the pygmy hippopotamus of Cyprus, from the Late Pleistocene with excellent chronological controls. The entire assemblage of this species is evaluated through relative skeletal abundance, demographics and distribution of burnt bone at the archaeological site Akrotiri Aetokremnos. The results of these analyses, in combination with paleoenvironmental data from the region, are used to address the relative impacts of human hunting, introduced competitors and/or climate change on this species’ extinction. This event is then discussed within the context of the larger debate over Late Pleistocene megafaunal extinctions, and of the relative impacts of humans and climate change.
Worley, Katrina (American River College)

The Interpretation of Carbonized Textile Fragments from Partial Cremations in California

California Indian populations utilized a variety of funerary practices, including cremation. Bodies prepared for cremation were often tied in a fetal position and wrapped with mats and other perishable materials. The process of burning and then smothering such funerary bundles as part of the burial ritual can lead to the carbonization of these materials. While textiles rarely preserve in the archaeological record, the process of carbonization can enhance their survival. The carbonized fragments are extremely fragile and brittle, typically having lost any indication of original color, but can retain details of their underlying structures and construction techniques. Even in this highly fragmentary state, it is possible to collect significant information about the textiles and other perishable artifacts that these fragments were once a part of. Archaeological collections often contain such specimens of “burnt basketry” that in many cases have never been adequately examined. This presentation will cover examples of such carbonized fragments, how they were interpreted, and show reproductions of some of the structures used.

Burned and Blown Away: Hearth-Mound Sites at White Sands National Monument

Recent research at White Sands National Monument highlighted the central role of geoarchaeology in a program of research that also integrated remote sensing, survey, and excavation in an effort to understand a complex archaeological record. The unique geology of the dunefield provides clues about the ages of sites, and geoarchaeological research helps to reveal both the landscape context when they were occupied and the resources that drew people to the area in the past. The study also has significant implications for understanding site formation processes – both those that lead to preservation and the processes that determine the trajectory of decay and eventual destruction of the traces of past occupations. The gypsum dunefield presents unusual challenges for archaeology, and our work to overcome those challenges led to further insights that are particularly important for managing cultural resources in that environment. In addition, the data generated by our investigations are relevant to answering more narrowly geological questions. Specifically, they help to reveal the rate and timing of dune movement and the history of growth of the dunefield. Finally, there are tantalizing clues that the archaeological data might provide insight into past environmental change.

The Materials of Colonization: Archaeological and Documentary Traces of Tristán de Luna’s Colonial Fleet

The material assemblages associated with sixteenth-century Spanish entradas in the Americas are still just beginning to be understood by archaeologists, not just as a means for tracing expedition routes across indigenous landscapes, but also as a basis for understanding the nature and consequences of these entradas. The discovery and excavation of two sunken ships from the 1559 colonial fleet of Tristán de Luna in Pensacola Bay has provided a unique opportunity to examine just such an assemblage from both an archaeological and documentary standpoint. The Emanuel Point I wreck, investigated between 1992 and 1998, and the Emanuel Point II wreck, discovered in 2006 and continually excavated to the present day by the University of West Florida, contain an extensive and well-preserved assemblage of mid-sixteenth-century Spanish artifacts. The assemblage includes not just the ships’ hardware and supplies, but also portions of the cargo loaded onto the fleet for the purposes of both colonization and military exploration of the coast and interior of the southeastern United States. In this paper we compare this assemblage to the corresponding financial account records, which provide a detailed documentary inventory of all materials originally loaded onto the fleet for the Luna entrada.

Patterns of Chenopodium spp. Seed Use at North Creek Shelter, Utah

Cultivation of annual species of goosefoot (Chenopodium/Amaranthus spp.) for food was practiced by the ethnographic Southern Paiute groups in southern Utah (Kelly 1932-1934, Fowler 1995). Yet our understanding of the archaeological use of these plants in the northern Colorado Plateau is limited. This study documents use of these important species over time and examines evidence for Chenopodium spp. management at North Creek Shelter (NCS), an archaeological site in the Escalante river valley of southern Utah. NCS contains a rich macrobotanical sequence spanning the early Holocene to Protohistoric times, of which Chenopodium spp. fruits and seeds form the largest dietary component. Here we present preliminary results on the use of Chenopodium spp. by examining 1) change in Chenopodium
spp. abundance throughout the Holocene archaeological record and 2) concurrent morphological changes in the fruit margins and/or seed coats. To our knowledge, this is the first attempt to evaluate archaeological evidence for management of Chenopodium spp. in the northern Colorado Plateau. Our findings provide a local history of Chenopodium spp. use and an archaeological context for ethnographic data on wild plant horticulture in the region.

Wragg Sykes, Rebecca (UMR 5199 PACEA, Université Bordeaux 1), Vincent Delvigne (Université Bordeaux 1 sciences et technologies, UM), Paul Fernandes (SARL Paléotime, 272 rue du lycée Polonais, 38250 V), Audrey Lafarge (Université de Montpellier 3, UMR 5140 « Archéologi) and Jean-Paul Raynal (Université Bordeaux 1 Sciences et Technologies, UM)

Palaeolithic exploitation of stone tool sources is still often considered from a site-centred perspective: 'living' sites are represented as centres of resource consumption, with stone entering them centripetally. The reality of how lithic sources fitted into webs of resource use and human movements is likely to be more complex. Within landscape-scale studies, it is essential to understand the lithic sources themselves: both in terms of mapping centrifugal movement of stone away from them, and activities being undertaken at these locales. This poster presents early results from a study of the Saint-Pierre-Eynac silcrete, Haute-Loire, France. In a region of mainly granitic/volcanic geology with sparse flint, this silcrete (silicified material from pedological processes) represents an accessible, abundant and technologically-flexible resource. Lithic artefacts have previously been found at Saint-Pierre-Eynac itself, and the silcrete is present in Middle-Upper Palaeolithic sites at least 40 km away. This project therefore has two aims: 1) The first detailed study of Palaeolithic behaviour at this type of lithic source, through aerial survey, large-scale surface collection, excavation and petro-archaeology; and 2) building a robust picture of Palaeolithic techno-economic exploitation of siliceous stone within the Massif Central landscape by clarifying where the stone was transported, and how it was utilised.

Wren, Colin (McGill University) and Ariane Burke (Université de Montréal)

[201] Climate Variability and Risk: Human Settlement of Iberia during the LGM

Climate change is a potentially significant factor affecting the spatial distribution and cultural dynamics of prehistoric groups. Understanding the impact of past climate change on human populations is also key to predicting how they might adjust to global climate change in the future. Climate change is defined by changes in the mean (e.g., temperature) or changes in variability (IPCC, 2007). Previously, millennial scale climate simulations have been used to investigate the impact of climate means on the spatial behaviour of prehistoric populations (Banks et al., 2013; Davies and Gollop, 2003; Gamble et al., 2004; van Andel, 2003). The goal of this research is to investigate the effects of climate variability at a fine spatial and temporal scale on the spatial behaviour of modern human populations in the Iberian Peninsula during the Last Glacial Maximum (LGM). Using an agent-based model, we show how human populations could have developed a risk-avoidance strategy towards highly variable locations within the Iberian Peninsula, and how this shaped the pattern of human settlement in this region during the LGM.

Wren, Linnea, Travis Nygard (Ripon College) and Kaylee Spencer (University of Wisconsin-River Falls)

[309] Establishing and Translating Maya Spaces at Tonina and Ocosingo: How Indigenous Portraits were Moved, Mutilated, and Made Christian in New Spain

Maya portraiture played transformative roles in shaping ritual, political, and social dynamics of Maya society, not only in the pre-conquest period but, at least in some cases, in the colonial era of New Spain. Our presentation studies two Late Classic portrait sculptures of Tonina kings that were moved, mutilated and made Christian through their reconfiguration as baptismal fonts in Dominican parish churches of Chiapas. We argue that the reworked sculptures were complex elements of an emerging visual culture in which differing audiences, both indigenous and Spanish, were active participants. For the Spanish, these sculptures, through their disfigurement, functioned as spolia, that is, as dramatic evidence of the military conquests of their armies and the spiritual might of their evangelizing faith. For the Maya, however, these sculptures, despite their disfigurement, continued to encode messages that had been embedded in their original forms. Thus, these sculptures were sites of cultural translation that permitted the continuity of indigenous ideas and the recontextualization of newly introduced Christian rituals and doctrines. Thus, we propose, these sculptures offered their multiple audiences the simultaneous potential for change and adaptation, for conversion and intransigence, and for compliance and resistance.

Wright, Rita (New York University)

[35] Enigmatic Polities and the Indus Civilization
The varied political strategies employed in the Indus are evident in the Harappans’ selection of landscapes, urban development, and the spatial practices that shaped political economy and integration. This is most evident in the regions of Sindh, the location of Mohenjo-daro, and in Gujarat, at Dholavira and its neighboring settlements. In the 1980s, Gregory L. Possehl (1982) identified eight “cultural and natural areas” that he regarded as sub-regions of the civilization that had “historical legitimacy and utility.” Later, Possehl (1992, 1997) introduced the concept of domains, and he emphasized the ecological variability of river systems, climate, and environmental differences. Each of the domains corresponded to the locus of a major Indus center, and Possehl (2003:6) suggested that it “might be the case” that domains corresponded to “Harappan polities.” Although Possehl’s domains have been cited and mapped by Indus scholars and have been useful in identifying ecological differences, the concept has not accounted for the systems of authority that materialized into sub-regional polities. It also has failed to clarify whether the sub-polities were integrated into the civilization’s political economy or were independent, source suppliers (Agrawal et al). In this paper, I suggest some solutions to these enigmas.

[36] Finding the Context: A European Perspective on Representing and interpreting Spatial Data from Archaeological Fieldwork as Linked Open Data

While considerable strides have been made in representing textual information as Linked Data within the domain of archaeology, how best to represent the important spatial components associated with fieldwork has remained elusive. The use of coordinates as point data is well suited to the structure of RDF, and has been put to good use with a variety of archaeological resources, but to truly represent the way archaeologists document and interpret the archaeological record requires the inclusion of data in two and three dimensions; therefore lines and polygons. This paper will outline research currently underway in Europe looking at ways to address this issue. It will feature work by May to understand diverse field recording systems, and issues of interoperability between them, work by Hiebel and Doerr on the ontological modelling of the geospatial components of archaeological data, specifically through an alignment of GeoSPARQL with the CIDOC-CRM, and work by Cripps on the G-STAR project, developing ontological modelling of the geospatial components of archaeological data, specifically through an alignment of GeoSPARQL with the CIDOC-CRM, and work by Cripps on the G-STAR project, developing ontological modelling of the geospatial components of archaeological data, specifically through an alignment of GeoSPARQL with the CIDOC-CRM, and work by Cripps on the G-STAR project, developing

Wright, Carrie (University of Oxford) and Julia Lee-Thorp (University of Oxford)

[53] The Ladies of Highfield and the Blokes from Hoy: A New Approach for Detecting Mammal Milk Consumption in the Archaeological Record

Two important stages in the early life of mammals involve milk; it's exclusively consumed during nursing and subsequent weaning is a mixed transition to solid foods. Milk is rich in calcium, thus calcium isotope ratios (44Ca/42Ca) may be a proxy for milk consumption but earlier studies lacked adequate controls. We describe a controlled study to assess the effects of milk consumption on δ44Ca values in enamel samples of modern sheep with known histories in order to identify the isotopic effects and duration of nursing. Results show a consistent 0.44-0.50‰ depletion in 44Ca in milk relative to grass, demonstrating that milk is a low 44Ca/42Ca source. First and second molars show a significant mean difference, with M1's consistently depleted in 44Ca by 0.18‰. These data reflect milk as the primary food during the M1's development with weaning occurring during development of the M2. Changes in the diet related to nursing and weaning, within and between molars, can be seen through the analyses of serial incremental enamel samples. Linking these results together with modern sheep management schedules to those from archaeological sites aids in identifying nursing and weaning duration in the past, and thus provides indications about past sheep management practices.

Wright, Katherine

[84] Domestication and Inequality? Households, Corporate Groups and Ground Stone Processing Tools at Neolithic Çatalhöyük and Other Early Villages in the Near East

Ground stone assemblages from early Neolithic villages in the Near East show different patterns from region to region, in social arrangements for food processing and in the use of ground stone artefacts in craft production. While there are points of comparison, the variations suggest diverse and culturally specific pathways in the development of early agricultural societies, particularly in food preparation practices. These are consistent with other data suggesting variability in plant-domestication pathways. Many questions remain unanswered about the early Neolithic: whether domestic groups were autonomous and self-sufficient; whether they had access to similar goods; whether households were competitive; whether specialization existed; and how domestic units articulated with corporate groups.
Feasting models emphasize household competition, but wide-ranging ethnographic studies show that many hoe-farming societies are egalitarian, with little material wealth, little inequality, and little wealth transmission. This paper explores these issues via ground stone assemblages from a range of early Neolithic sites across the Near East. One example is Çatalhöyük East, where analysis of 2429 artifacts from 20 buildings and 9 yards reveals a mix of egalitarian features and emerging social complexity. However, data from other Neolithic villages do not necessarily mirror the trends seen at Çatalhöyük East.

Wright, Lori (Texas A&M University, Department of Anthropology)
[126] Disability, Compassion and the Past — Thoughts from my Wheelchair
A recent publication by Tilley and Oxenham (2011) has revived interest in the use of skeletal pathology data to make inferences regarding empathy and compassion of past peoples and cultures, as evidenced, indeed, by this symposium. Does the survival of an individual through a protracted illness or impairment evidence compassionate care or, if the remains are of sufficient antiquity, shed light on the evolution of a capacity for empathy? How reliable are interpretations of impairment and pain when based on skeletal pathology alone? Can bioarchaeologists assess well being reliably? Having spent the summer of 2013 confined to a wheelchair and unable to walk, I have had the opportunity to reflect on the issue of empathy (and pain) in the context of physical impairment, and the familial and social ramifications of individual illness in our own culture. My experience leaves me wondering why this line of inquiry keeps raising its head? At this writing, I conclude that such inferences tell us more about our own culture than about the past.

Wright, Joshua (Oberlin College)
[149] Detecting Microenvironments used for Nomadic Pastoral Habitation
Archaeological survey and environmental data are frequently of different scales. Active, modern nomadic pastoralists clearly exploit identifiable microenvironments to protect their habitations and herds. Locales identified through archaeological survey frequently match these profiles. This paper describes the detection and modeling of those microenvironmental locales as used in the present and the past. Using archaeological and ethnographic data from Baga Gazaryn Chuluu in Dundgovi, Mongolia, a desert-steppe island of small- and large-scale heterogenous terrain, and drawing on environmental data of different scales including remotely sensed landcover and soils, large-scale DEM, surface hydrology and archaeological survey material, we are able to model potential seasonal shelter, flash flood survivability, visibility, and access in both current and ancient inhabited locales.

[186] To Fish or Cut Bait: Changing Subsistence Strategies in the Face of Holocene Environmental Changes in Turkana, Kenya
Oscillating lake levels during the Holocene in eastern Africa reflect changes in the distribution of rainfall and resources available for human use. Between 12.0-0.1 ka, the closed basin of Lake Turkana, NW Kenya underwent 10 oscillations of >10m in absolute lake level on sub-century timescales. Recent analysis of a relict tombolo west of Lake Turkana at Lothagam shows high stands at 11.4-11.6 ka, 10.4-10.8 ka, and 6.3 ka. The Early Holocene high stands occur within a moist period of generally high and stable lake levels. The Middle Holocene high stand follows a period of generally lower lake levels and at least three >10m transgressive or regressive events. The dramatic shifts in lake level demonstrated here suggest likely fluctuations in local rainfall, vegetation, and aquatic and terrestrial fauna. Humans living in the basin would have had to adjust subsistence strategies on short notice, accommodating to physical and ecological changes in landscape and rebalancing emphasis of aquatic vs. terrestrial resources. Regression after the 6.3 ka highstand created vast plains between the lakeshore and volcanic hills that would have provided new grazing habit for terrestrial herbivores and, slightly later, incoming livestock as herding became established in the area.

Wright, Patti (University of Missouri--St. Louis) and Julie Morrow (Arkansas Archaeological Survey)
[327] Plant Exploitation Strategies Used by the Mississippian Occupants of Northeastern Arkansas
The lowlands of northeastern Arkansas provide an interesting setting for examining crop selection strategies
and cropping systems during late prehistoric times. Between cal. AD 900 -1500, Mississippian populations occupied the Mississippian River floodplain east of Crowley’s Ridge as well as the lowlands to the west. In this study, we assess intersite variability in the presence of crops such as members of the starchy seeds complex, maize, and sunflower as well as wild plants such as acorn, persimmon, and giant cane. We explore ecological and cultural variables affecting the decision to adopt and utilize these plants.

Wright, Henry (University of Michigan)

[329] Production, Exchange, and Consumption in the Uruk World

The seemingly homogenous material inventories of Uruk settlements mask patterned variability at many levels. Variability in raw materials, production sequences, and microstyle can be used to evaluate new models of the organization of production, the social relations of producers, the exchange of objects and craftspeople, and similarities and differences in consumption. Evidence from Upper and Lower Mesopotamia, SW Iran, and SE Anatolia from the middle and late portions of the Uruk trajectory will be used in this discussion.

Wriston, Teresa (University of Nevada, Reno) and Geoffrey M. Smith (University of Nevada, Reno)

[24] The “Old Dirt” and Paleoindians of Warner Valley, Oregon

Following in the footsteps of Jonathon O. Davis and Fred Nials, we continue our search for “old dirt” to find the earliest peoples in the Great Basin at the University of Nevada, Reno. This approach has proved enormously successful in our recent research in Warner Valley where we have discovered numerous fluted and stemmed projectile points in association with a dated recessional beach bar. Although people using stemmed points followed the pluvial lake’s recession into the valley interior at the end of the Pleistocene, fluted points disappear from our record. Long periods of erosion during the mid-Holocene scoured many parts of the basin after the lake receded, but water did persist in the lowest portion of the valley, providing valued resources that drew people throughout the Holocene even as the basin’s northern reaches were scoured of sediment during the Altithermal. Our geomorphological and archaeological studies have enabled us to trace Paleoindian and Archaic use of the dynamic landscape of north Warner Valley and further contribute to the understanding of early peoples in the Great Basin.

Wrobel, Gabriel (Michigan State University)

[335] Understanding the Multi-Scalar Complexity in Archaeological Skeletal Collections and Its Implications for Analysis

Bioarchaeological analysis is highly dependent upon the scale of archaeological investigation. The size and nature of skeletal samples determine not only which methodological approaches are appropriate, but also provide clues useful for contextualizing biological data. This paper explores potential problems with different types of analyses that result from scalar variables not being taken into consideration. For instance, many researchers tend to treat archaeological samples as “populations” or assume that differentiation in death necessarily corresponds to meaningful social distinctions within a population in life. A case study from central Belize illustrates the variable composition of burial groups from different locations across the landscape, providing several viable explanations for differential burial treatment. In conclusion, the implications of underlying assumptions related to the scale of social units represented by skeletal collections are discussed in relation to archaeological research designs that create these collections.

Wyckoff, Don

[280] The Primrose and Anthony Sites: Calf Creek Base Camps and Staging Areas in Central Oklahoma

Located in Oklahoma’s Washita River drainage, the Primrose and Anthony sites represent two diverse kinds of camps frequented by Calf Creek hunter-gatherers. Situated just north of the Arbuckle Mountains, the Primrose site has yielded an array of chipped stone tools and cores, mainly of Frisco flint for which the nearest bedrock source is 50 km east. Extending along a dune covered 1st terrace, finds of biface caches, diverse kinds of cores, and broken preforms, the Primrose assemblage bears witness to intensive heat-treatment of the flint as well as gearing up for forays in several directions. In contrast, the Anthony site is approximately 115 km up the Washita drainage and is atop the high divide with the Canadian River. The Anthony assemblage is mainly broken spear points and flake tools of Alibates agatized dolomite, with well known quarries some 350 km west. The Anthony assemblage does contain
notable amounts of tools made from nearly all knappable stone used by Calf Creek groups in Oklahoma. These two intensively utilized sites offer contrastive evidence of resource use, encampment practices, and band aggregation. Artifacts scattered over the nearby landscapes of both sites attest to local foraging and hunting.

Wygal, Brian [173] see Krasinski, Kathryn

Wygal, Brian (Adelphi University) and Kathryn Krasinski (Fordham University) [282] Late Glacial Exploration and Colonization of the Last Beringian Frontier
For most people today, the concept of being alone in the wilderness or even in a wireless dead zone is particularly frightening. But for the first Americans to enter and establish territories in the New World, being isolated in a new land may have been commonplace and even culturally engrained. Heavily glaciated during the LGM, the Susitna region of southcentral Alaska was sparsely occupied during the Late Pleistocene and may have undergone thousands of years of marginal exploration by the earliest Alaskans prior to becoming fully colonized in the early Holocene. As such, the colonization of empty landscapes by small-scale foragers has become a significant area of research in the Susitna Valley. This paper assesses the relevant colonization models as they apply to Eastern Beringia with a particular emphasis on the initial phase of the process, exploration of a new territory. Recent excavations in the middle Susitna Valley suggest the first explorers of the area arrived soon after deglaciation and lacked established trade networks and lithic procurement sources when compared to the long distance transport of obsidian that occurred in later occupations.

Wylde, Michael (University of Florida), Ellen Lofaro (University of Florida), Susan deFrance (University of Florida) and Paul Goldstein (University of California, San Diego) [53] A Dog Burial from Rio Muerto
This presentation examines the place of the dog in the Andean society of Tiwanaku. The mummified remains of a small dog were recovered from a domestic context at the Rio Muerto site located in the Osmore River drainage of southern Peru. The Rio Muerto complex is one of several Tiwanaku settlements in the region with dates ranging from ca. 700 to 1300 A.D. Canid burials and iconography may be observed during many periods of Peruvian prehistory, with much of the material originating from northern archaeological sites. An initial overview of the history of canids in pre-contact Peru offers preliminary information from the archaeological and ethnographic records to suggest possible avenues of study focused on ancient dogs of southern Peru. Were dogs used as status symbols, pets, dedicatory offerings, or herding dogs for ancient llama caravans from the altiplano? Offerings of young camelids and dogs have been found buried beneath floors and entryways of houses at Rio Muerto M43 and at other Tiwanaku sites in the Moquegua colony. We describe the burial context of the dog mummy from the Rio Muerto site and the probable role of the dog as an indicator of status in this large Tiwanaku immigrant community.

Wyllie, Cherra (University of Hartford) [204] Reconsidering Cerro de las Mesas Ceremonial Sculpture
Classic period Cerro de las Mesas rulers decreed their power on monumental relief-carved stone, the raw material imported at great distance from the clay rich Mixtequilla. The use of stone stelae connected them with their Olmec ancestors, proclaiming Cerro de las Mesas as the inheritor of a centuries old tradition. Gradual changes in costume, gesture, signs, hieroglyphs, and symbols on these monuments document the ways that regional traditions and external influences impacted elite roles and an ever-developing cosmology. These were the last rulers of the southern Gulf lowlands to erect stone stelae; and yet Cerro de las Mesas maintained this practice for centuries. As the influence of Cerro de las Mesas waned artists of the Mixtequilla abandoned the use of stone in monumental art.

Wynn, Thomas [26] The Cognitive Implications of Levallois
Palaeolithic specialists have long accorded the shift from façonnage to debitage strategies an important status in the evolution of lithic technology. Epitomized by classic Levallois reduction, debitage strategies
instantiated a different approach to the task of producing useable products. Such strategies are descriptively more complex than even the most sophisticated biface reduction: descriptions of Levallois include more discrete steps, and a more complex hierarchy of steps. Does this descriptive complexity reflect the evolution of specific cognitive abilities, and if so, what might they have been? An explicit model drawn from cognitive neuroscience, that of expert performance, provides an appropriate theoretical framework for contrasting Levallois cognition with that of earlier strategies. Through this perspective it is possible to identify two specific cognitive developments implied by Levallois reduction: 1) an increase in long-term memory capacity in the guise of a greater variety of active cues and retrieval structures, and 2) an increase in working memory capacity as reflected in rapid shifts in technique. Levallois has no necessary implications for language or other semiotic behaviors.

[108]  Precolonial African trade networks and the 'Small World' paradox
Trade is a pervasive theme in the archaeology of precolonial African societies. Control over production and the movement of objects is frequently invoked as either cause or result of the emergence of socio-political elites; yet, it is also increasingly recognised that even small-scale societies were deeply interconnected and often entangled in larger global economic trajectories. This trade, though fundamental, is rarely considered as a process, and its mechanics are often glossed based on simplistic models of down-the-line exchange or central place modelling of trade entrepôts. In this paper, we consider two areas deeply implicated in medieval trading networks, comparing the West African Sahel with the East African coast. Network theories are used to consider the dynamics of premodern trade; in particular we consider the Small World theory of interaction, suggesting that comparatively small groups of traders might have connected large numbers of people over long distances.

[297]  An Early Hemudu Social Learning Strategy Reflected by the Pattern of bone Spade Production, 7,000-6,000 B.P., China
Bone spades crafted from water buffalo scapulae were used for rice cultivation and constructing structures in early Hemudu culture dating to ca. 7,000-6,000 BP in eastern China. These bone spades had sophisticated hafting designs that were costly to make. Surprisingly, the production of these scapular spades may not have been carried out by well-trained specialists, but by the users themselves, i.e., self-sufficient household craftspeople, through emulation. Several clues jointly led to this conclusion, including the presence of (1) technical variations at almost every stage of scapular spade manufacture that left traces; (2) high product variation reflected in morphological details regardless of similar designs; (3) unequal, low to moderate levels of manufacturing skills observed on the finished products that were used regardless of differences in quality; and (4) very little training and practice as displayed by replicated mistakes and an inadequate amount of "practice pieces." The social learning strategy of emulation may have contributed to extended long tradition of using bone spades even when raw material was in short supply.

Xiuhtecutli, Nezahualcoyotl (Tulane University)

[275]  Surrounded? Assessing the Aztec Blockade on Tlaxcallan through Surface Evidence from Tepeticpac
This paper presents evidence for domestic strategies at adopted by middle status households at the Postclassic site of Tepeticpac. Tepeticpac formed part of one of the most important altepetl of Tlaxcallan, the polity centered in the modern state of Tlaxcala, Mexico, which was never conquered by the Triple alliance of the Basin of Mexico headed by the Mexica of Tenochtitlan. The evidence recovered during surface collections from middle status terraces at Tepeticpac suggest that although the ethnohistoric sources suggest an economic block imposed on Tlaxcallan by the Triple Alliance, goods continued to flow into Tlaxcallan, as recent surface collections show the presence of artifacts proceeding from areas controlled by the Mexica and their allies.

Yaeger, Jason (University of Texas at San Antonio)  
[21] Hinterland Settlement Histories, Population Mobility, and Political Dynamics in the Mopan River Valley, Belize  
Archaeologists have considered population mobility largely from the perspective of long-distance and large scale migrations, such as those documented by ethnohistory. These infrequent events can be historically momentous, and consequently they overshadow the much more frequent population relocations that happen on smaller social and spatial scales, as households and communities move to the other side of the community, polity, or valley. This paper examines the pace and shape of founding, growth, and abandonment of hinterland settlements associated with two major centers (Xunantunich and Buenavista). This comparative study allows the author to suggest that hinterland community growth often involved in-migration, and that geomorphological, economic, and political factors all structured people’s decisions to move into these settlements and to leave them. The results have implications not only for understanding population mobility at smaller scales, but for understanding how the decisions of hinterland families were shaped by and also structured larger-scale economic and political dynamics.

[273] The Prospect of Autoregulation in the Antiquities Market: Testing and Interpreting Auction Data  
For two decades auction catalogs have provided primary sources for academic inquiry into the global trade in antiquities. However, qualitative auction catalog data is often treated quantitatively and quantitative auction catalog data is rarely tested. If auction data is to be used for market analysis it requires rigorous assessment, intuition is not sufficient. In particular, pro-trade commentators claim that buyers, fearful of antiquities regulation and repatriation requests, prefer to buy antiquities with older provenance. This is so-called autoregulation: the idea that objects which surface on the market after the signing of the UNESCO convention, or are subject to a repatriation claim, will be rejected by fearful buyers. The market favoring antiquities with older surface dates is presented as evidence that the trade can police itself and that additional (even current) regulation is unneeded. In this paper we explore the idea of autoregulation of the market using the particulars of a single hotly-contested antiquities auction: Collection Barbier-Mueller Art Precolombien, offered for sale at Sothebys Paris in 2013. Although we employ statistical methods to test ideas of autoregulation, we ultimately believe that many important factors involved in the sale of antiquities at auction are not captured in this analysis.

[125] Managing High Densities of Archaeological Sites on San Clemente Island through Programmatic Compliance and Modeling  
Where high densities of archaeological historic properties present conflicts with required land use for military training, there are programmatic historic preservation compliance and modeling strategies that provide opportunities to develop creative balances between federal regulatory requirements, academic research and sustaining military readiness. San Clemente Island presents a case study in the use of new approaches to predictive modeling that both sustain use of the island’s operational ranges for readiness training and enhance our understanding of the island’s abundant and well-preserved archaeological record.

[265] The Nature and Archaeology of Spring Lake, a Persistent Place in Central Texas
With artifacts representing periods of occupation from Clovis to Protohistoric, and up to present, the San Marcos Springs is a persistent place on the archaeological landscape of central Texas. The unique and rich combination of biological, geological, and hydrological resources could affect the suitability of this location, and the rich, hunter-gatherer history of the region adds a layer of complexity. How did availability of resources change through time? And is there evidence of differential use and varied intensity of occupation? This poster examines the natural and cultural records of this location in pursuit of explaining what makes it a perennial choice for habitation and describing how it was occupied through the Holocene.

La semántica de la imagen bilobulada en la cabeza en el antiguo hombre costeño del área central andina (Perú). ¿Una relación con el culto lunar?

El hombre desde la antigüedad tuvo la idea de modificar y decorar su cuerpo en una diversidad de coloridas formas simbólicas; y entre las prácticas corporales de más arraigo cultural, fue la modificación cefálica. Las dimensiones de lo imaginario, de ese conjunto de imágenes y sus relaciones, constituye el capital simbólico del pensamiento humano. Este imaginario es la intersección central, que permitirá esclarecer en este caso, el problema de investigación, relativo a la significación, al simbolo y a la dimensión imaginaria del antiguo hombre andino y su práctica cultural de modificar la cabeza con una forma de imagen bilobulada. Una semántica de las imágenes, que le dio una configuración metafórica a su cuerpo, lienzo de redes simbólicas de su cosmos. La imagen bilobulada, representada en el arte con la diosa lunar y la diosa del mar, estaría aludiendo, a que ¿La cabeza bilobulada de los antiguos costeños, estaba asociada con los cultos lunares? Este es el objetivo de la presente ponencia.

An Open Access Repository of Geophysical Survey Data for Historical and Experimental Human Burial

While geophysical instruments are excellent tools for locating subsurface anomalies, there are inherent difficulties in using these technologies to detect and characterize human burials. The problem is linked to an inability to differentiate a burial from other environmental anomalies when detection of rock, roots or other non-burial features is regarded by others as a failed or unsuccessful search. We argue that this problem does not lie in the detection threshold but more in an unawareness of the suite of geophysical characteristics that may be unique to burials. To correct for this we construct a digital “comparative collection” of geophysical survey data to over known burials to aid in the characterization of burial related anomalies. The collection includes raw and processed geophysical survey files in a standardized open access and “Linked Open Data” format within OpenContext.org. The data publication include at least five historical (several still active) cemeteries in varying soils and surface conditions that were surveyed with one or multiple geophysical techniques including GPR, soil resistivity, and geo-magnetics. Included also in the database are geophysical surveys collected on multiple experimental human burials at the University of Tennessee Anthropological Research Facility (ARF).

Ditches for Defense, Deterrence, and Social Delineation: Examples from the Neolithic and Copper Age of Southeastern Europe

Ancient earthworks have fascinated antiquarians and archaeologists alike. While often shrouded in myth, many monumental ditches and palisades have been interpreted as either fortifications or symbolic structures with astronomical alignments and “cultic” significance. While criteria used to differentiate between these two functions have changed since the time of John Aubrey, Louis Siret, and Squier and Davis, until very recently, most discussions have favored one of these two interpretations or the other. While some ancient earthworks were “vacant” gathering places located away from settlements, ditch and palisade complexes that enclose tells and villages seem to have had both defensive and social functions. Research by the Körös Regional Archaeological Project in southeastern Hungary has shown that ditches and palisades surrounding Neolithic tells and small villages from the early Copper Age exhibited some of Keeley’s universal features of defensive enclosures. These earthworks also seem to have marked the
territories of settlement-shifting agriculturalists and to have served as expressions of social segmentation and substitution in the built landscape of agropastoral tribes. The communal acts of constructing the earthworks seem to have helped integrate dispersed groups of autonomous villagers and to have strengthened the social fabric and collected memories of these early Europeans.

[109] Late Paleolithic Taphonomy and Subsistence in the Nile Valley: Faunal Remains from Kom Ombo (Egypt) and Wadi Halfa (Sudan)

Data on Late Pleistocene subsistence trends and settlement patterns constitute the necessary background for studying the punctuated emergence of sedentism and food production in the Near East. While the Levant and Zagros regions figured prominently in discussions of the Broad Spectrum Revolution and the domestication of animals, the archaeological record of the Nile Valley has rarely been integrated into the picture. Salvage excavations and surveys in the Kom Ombo Plain (southern Egypt) and opposite Wadi Halfa (northern Sudan), conducted in the 1960’s by Yale and Colorado Universities produced several important faunal assemblages associated with Late Paleolithic (ca. 22.5-14.5 years BP) sites with diverse lithic industries. I present the results of a comprehensive taphonomic-zooarchaeological analysis of the faunal assemblages, with the aim of first, understanding their depositional, post-depositional and collection biases and second, characterizing the latest Pleistocene economy and human ecology in the Nile Valley. The degree of reliance on big game hunting, site function and occupation intensity will be used to shed light on forager life-ways in the Nile Valley during a period of major developments across the Near East.

[282] Isolation and Cultural Complexity: Key Arguments from Coastal Alaska, NE Asia and Tierra del Fuego

Coastal Alaska and Tierra del Fuego offer insights into processes by which intellectual traditions in hunter-gatherer archaeology have linked cultural complexity and isolation. Both cases reflect the “Ultima Thule” view in which distance from major urban centers (both pre- and post-contact) is linked both with primitivism and cultural stability. This view has proved to be false. Cultural stability has been assumed in spite of both early demonstrations of significant technological change in relation to intensification of sea mammal hunting, and increasing evidence (in the Alaskan case) of exchange of material culture across Bering Strait. These assumptions were frequently made even when it became increasingly obvious that such isolationist positions could not be held in adjacent NE Asia, where diffusion of pastoralism from central Asia and horticulture from north China, along with associated technological complexes related to subsistence and warfare, was often linked to the northward movement of groups. Recent reassessment of these positions has been made possible by a greatly improved understanding of regional climate change which underlay the movements of pastoral groups and, for both coastal Alaska and Tierra del Fuego, the development of cultural complexity in times and places that encouraged population growth in resource-rich, ice-free environments.

[71] From Hang Cho to Rashaan Khad - East Asia at 40,000 B.P. and after

While evidence suggests that the Hoabihnian industry might have appeared already by 40,000 BP in northern Vietnam and adjacent areas, markedly different assemblages are known from higher latitude areas in East Asia. In central China and Korea, Acheulian-like handaxe industries appear to have had continued even after 30,000 BP. On the other hand, evidence of ‘modern’ human behavior is clearly seen at pre-35,000 BP sites in eastern Japan. Also, the vast dry landscape from inner and outer Mongolia is with still characteristic assemblages so that perhaps blade industry with a hint of levallois technique had appeared there before 40,000 BP. Despite all the problems and sampling biases in the available data, such inter-regional difference seems to reflect not only the different adaptive behaviors but also the biological complexities of the inhabitants during the MIS 3 in East Asia, which are only poorly understood.
Yi, Jianping (Chinese Academy of Social Sciences)  
[288] Stratified Societies without Centralized Leadership: Yi in Southwestern China  
Before 1956, societies in the Great Liang and Small Liang mountains in southwestern China were rigidly hierarchical. "Zimo," hereditary chiefs, were the first estate. The second estate, "Nuohu," were freemen. Zimo and Nuohu were protectors of the third estate, "Qunuo". The fourth estate, "Aija," and the fifth estate, "Gaxi," were slaves. Zimo and Nuohu possessed the majority of "the basic resources that sustain life." However, members of same estate, particularly of Zimo or Nuohu, were equal. Since the mid-Ming Dynasty Nuohu gradually drove off Zimo out of major areas, especially the central area of the Great and Small Liang mountains, and as a consequence finally only four estates were left there. Interestingly, there was never any permanent leadership in the areas dominated by Nuohu; the so-called chiefs were only temporary leaders, no more than men of prestige. Nuohu and Qunuo were organized in patriarchal clans. Important decisions were made in a variety of assemblies. Customary law was used to maintain order. Such highly stratified and strictly hierarchical societies with an unique equalitarian system within the estate are strikingly different from any societies described by Elman R. Service and Morton H. Fried.

[10] Travelin' Rhyolite: Sourcing Lithic Raw Material in Relation To The Johannes Kolb Archaeological Site (38DA75)  
Lithic artifacts recovered from excavations at the Johannes Kolb Archaeological Site (38DA75), located near the Great Pee Dee River in Darlington County, South Carolina, provide archaeologists with information that can be used to address subsistence-settlement patterns during the Early Archaic Period in the Southeast. Preliminary analysis indicates that the predominant raw material is porphyritic rhyolite, a metavolcanic rock type known to outcrop in the Uwharrie Mountains of North Carolina, located 75 miles upriver from the Kolb site. This case study will determine whether Early Archaic people traveled great distances to obtain raw lithic material for stone tool manufacture or if they took advantage of local raw material found in cobble form in the Great Pee Dee River. Sourcing of raw stone material is critical for studies of human movement across landscapes and for detecting possible trade or exchange activities. To determine the provenance of the raw stone material, cobbles from the Great Pee Dee River, lithic debitage, and stone tool artifacts associated with the Early Archaic Period at the Kolb site will be analyzed through X-Ray Fluorescence. The results stand to contribute to a better understanding of mobility, resource procurement, and territoriality among Early Archaic hunter-gatherers in the Carolinas.

[130] Ball Courts and Political Organization during the Terminal Classic in the Cochuah Region, Quintana Roo, Mexico  
Ballcourts, arenas for displaying rulers' power, were linked to the political landscape. During the Terminal Classic Period the Cochuah Region exhibited changes in distribution of ballcourts; during this time ballcourts were constructed at tertiary sites. Construction of ballcourts in tertiary settlements suggests a change in the political nature of the ball game - the capability of low ranking sites to host ball games. This action, before the Terminal Classic Period, was only a privilege of the high ranking sites where king had his sit. A number of hypotheses can be examined for comprehending possible mechanisms behind the changes.

[291] Kinship, Identity and Ancient Egyptian Bioarchaeological Relatedness

With notable exceptions (such as dental non-metric studies by Irish), bioarchaeology in Egypt has tended to focus upon one site or one aspect of health and disease, rather than the interrelationships between peoples and places. This is disappointing given the complex nature of trade routes through the area, such as the contrast between the relative simplicity of movements along the Nile Valley and the more complex point to point movements involved in the caravan routes through the desert oases. These route patterns have determined implications upon kinship networks and the social knowledge of others. By contrast, Egyptology itself is developing concepts of social identities and personhood, linked with kinship and ethnicity patterning within Egypt. The paper debates the biological aspects of archaeological identity and the interactions with the understanding of kin groupings and kin relations in a series of Egyptian skeletal samples, using both postcranial and cranial variation. Results are then linked to the excavation records, which, despite the paucity of detailed records for early excavations, demonstrate potential trends in understanding of Egyptian concepts of kinship.

[122] Sounds and Rituals in Action: Prehispanic Maya Musical Instruments

This paper presents new findings concerning the archaeological and acoustic study of musical instruments from various Maya sites in the Yucatan Peninsula. The analysis of these materials combines new theoretical perspectives with a consideration of the archaeological contexts of artifacts, their relationships with other registered materials, their acoustic characteristics and the spaces in which they may have been played. This analysis reveals varied usage patterns for different contexts such as performances, sacrifice, and burial. Included in this paper is a discussion of physical methodology, such as the use of a mobile laboratory to measure the musical instruments in a controlled space. The laboratory sound analysis focuses on the rate of occurrence of different musical intervals and tones. Sound analysis along with archaeological contextual data allow us to develop a dynamic comprehension of the use and spatial distribution of prehispanic Maya musical instruments.

[89] Urban Transformation and Landscape Change Surrounding the Nadin Archaeological Site in the Ravni Kotari Region of the Eastern Adriatic

In antiquity, Ravni Kotari was arguably the most urbanized region along the Dalmatian coast, and the area in general has experienced a process of urbanization and landscape change spanning more than 2,000 years. The Nadin archaeological site reflects a complex history that tentatively includes incipient urbanization in the Late Iron Age (~400-150 BC), a Roman municipium (~150 BC-AD 500) followed by Late Antiquity abandonment, a light reoccupation during the late medieval period (~AD 1000-1400), a 16th century Turkish fort, and a contemporary village. However, the archaeological study of urban change and accompanying landscape evolution in the region is still in its infancy. This paper outlines current opportunities and challenges for archaeology to contribute to a more robust understanding of long-term urban-ecological relationships in northern Dalmatia using Nadin as a point of discussion. Given the tremendous mix of environmental diversity, rich cultural history, and current economic growth and development along Croatia’s Adriatic coast, the implications of such studies for contemporary land use
practices and policy development are also addressed.

[72] Gazing Mesoamerica from Nueva Vizcaya: Postconquest Technological Developments and Identity among the Tepehuan and Other Indigenous Groups
Almost all the archaeological investigations carried out to date in the northern Mexican state of Durango-Colonial Nueva Vizcaya- have focused their efforts on building basic culture history of prehispanic sites in the region. Only few research projects have considered postconquest settings as part of basic settlement pattern studies, leaving material culture largely unstudied.

As part of the "Proyecto Arqueológico Sextín" we are building a "deep chronology" of a small river valley in order to contextualize a wide range of facets of the everyday lived experience of the Tepehuan inhabitants through centuries of occupation. In this paper, we analyze technological aspects of ceramic and architectural production in order to show how the indigenous and mestizo population displayed new acquired tastes as part of an intricate process of identity negotiation after the Spanish invasion.

[300] Culture Change at the End of the Bronze Age: Iapodian Burials in Croatia
The Iapodian culture of northern Croatia provides a unique case study for the development of social and political complexity, evident, in part, through shifting burial practices during the Bronze Age (ca. 2300-800 cal B.C.). The Iapodian cultural group employed local, traditional forms of rock mound burials (tumuli) and adopted crematory practices from contemporaneous Central European Urnfield groups. The timing and nature of this shift remains unclear as the Iapodians are one of the least studied cultural groups in the region.

Our preliminary analyses focus on human remains from three key Iapodian sites that are thought to span this important period: Bezdanjaca, Sultanov Grob, and Trosmarija. We report on the preservation of bone and the feasibility of collagen extraction for future studies in the Iapodian region using several standard metrics, including gelatin yield, collagen C:N ratios and stable carbon and nitrogen isotopes. We also report new radiocarbon dates and suggest a preliminary chronology for the area.

Zborover, Danny (University of Calgary/ US-MEX, UCSD)
The demarcation of sociopolitical boundaries is an essential element of indigenous ‘territorial narratives’,
as is expressed by the surviving documentary record and the associated archaeological record. The need for geographical specificity in commemorating victories and demarcating territory seems to have motivated the early development of Mesoamerican logographic toponomy, and further helped to promote a place-based corporate identity. In this presentation I will argue that this tradition has its longest recorded trajectory within the Oaxacan cultures of southern Mexico, following from Monte Alban’s ‘conquest slabs’ in the Terminal Formative; the topo-genealogical stela of the Classic period; the Postclassic historical codices; the Colonial period lienzos, mapas, and titulos; and through the contemporary community maps and territorial oral traditions. This long-term process can be exemplified through several diachronic case studies in the Chontal highlands, where indigenous domination, colonialism, factionalism, and resistance had created a multi-bounded sociopolitical landscape. This millennial convention can further explain present-day phenomena such as the multitude of municipal divisions and inter-community territorial conflicts in the state of Oaxaca.

Lithic Landscape of Barrow Island: A View from the Open Scatters

Initial examination of surface artifact scatters across Barrow Island (BI) indicates strong reliance on extra-local lithic materials available only on the mainland, particularly in the Pilbara region. Less extensive exploitation of silica-rich limestone deposits occurring on the island is best documented at a quarry workshop at the extreme northern end of BI. Both classes of raw material occur in variable quantities in the Boodie Cave deposit, suggesting that stratigraphic pulses of the representation of inland versus coastal tool stones may have recognizable expressions in the open-air surface record of the island.

Bison Wealth, Ritual Wealth: Rethinking the Impact of Abundance on the Rhythm of Hunter Societies

Approximately 1,100 years ago, climate, ecology, and demography conspired to create thriving conditions for bison herds and their increasingly specialized human predators along the northern Rocky Mountain foothills. The consequences of this historical juncture are currently the focus of interdisciplinary, multi-scale studies in Canada and the United States, where researchers are mapping bison and people at large scales in order to determine landscape use, political boundaries, and the reach of interregional trade, as well as to re-conceptualize the relationships between bison abundance and organizational complexity. This paper examines the material record of abundance among pre-contact bison hunting societies on the northwestern Plains and its short- and long-term impacts on social and political systems. Specifically, it discusses the relationship between bison abundance and the generation of different kinds of wealth, in particular, ritual wealth and social power and the impact of this wealth on the rhythms of everyday life.

Modeling Cultural Responses to Volcanic Disaster in the Jama-Coaque Culture, Coastal Ecuador

The cultural impacts of catastrophic Holocene volcanism are characteristically variable throughout the world due to a wide range of factors such as magnitude of the eruptive event, proximity to the eruption, the geographic and ecological settings of the eruptive footprint, and relative social and political complexity of the societies affected. The reasons why one society succumbs to volcanic disaster while another may recover are complex and not subject to invariant laws. Even in cases where recovery is possible, different pathways may be followed depending on a host of contingent factors. Archaeological research in the Jama Valley of coastal Ecuador has revealed evidence of three volcanic eruptions emanating from the northern Ecuadorian highlands to the east, all three of which represent major stratigraphic breaks in the regional archaeological record. The third of these volcanic events, occurring at ~ 400 C.E., significantly affected the Muchique 1 and 2 chiefdoms of the Jama-Coaque Tradition in northern Manabf province. This paper offers a model of differential human response to catastrophic volcanism that focuses on human-resource imbalances resulting from such events and identifies a series of contingent circumstances in which complex chiefdoms may cope, and even flourish, in the aftermath of disaster.

Feeding the Senses: Technologies of Taste and Pleasure in Colonial Tehuantepec, Mexico

Excavations at the colonial-era Native hamlet of Rancho Santa Cruz near Chihuitán, Oaxaca, yielded a large inventory of locally made pottery, including an innovative ware we call Tablón Orange. Largely traditional in its manufacturing and decorative modes, the ware nonetheless represents a marked break in the ceramic traditions of the southern Isthmus of Tehuantepec. We examine here the significance of two aspects of the Tablón Orange assemblage: (1) its brightly painted decorative motifs, which we consider to be a response to the aesthetic challenge of introduced majolica wares, and (2) two novel vessel forms, palmatorias and copitas. The latter served a complex of desirable technological introductions from Spain, centered on candlelight, fireworks and distilled alcoholic beverages, introductions readily embraced by the Isthmus Zapotecs. We examine historical records for both Spanish and Isthmus Zapotec views of the behaviors associated with this complex and use these archaeological manifestations to discuss broader issues of colonial hybridity and Native agency.

Mound 72’s Principal Individuals: A Reassessment of Sex and Its Importance to Mississippian Mortuary Practices

Cahokia’s Mound 72 is one of the most socially complex and frequently discussed burial features in the Eastern Woodlands. The principal feature of this mound is the interment of two individuals: a primary, extended individual buried supine on top of 20,000 shells beads and another primary, extended individual beneath the beads. Original reports indicate both individuals were male. However, recent studies conducted by multiple observers using independent lines of evidence suggest the individual beneath the beads was actually female. A female in this principal burial location requires a fresh look at how Mound 72 is viewed. In this study, we discuss the portrayal of women in Mississippian archaeology, drawing on similarities between the Mound 72 mortuary program and other Mississippian sites in the region. In light of these new insights, we offer an alternative perspective on the symbolism depicted in the burial features of Mound 72.

Panquilma Archaeological Project: The Importance of Building Partnerships with Local Communities as a Way to Foster Social Inclusion

It has recently become increasingly important for archaeology practitioners to develop new and more inclusive lines of actions regarding management of cultural heritage and community relations. Socioeconomic development and access to cultural resources are closely linked especially in countries with high levels of poverty and social exclusion. This paper arises as a way to explore community relations around the archaeological project of Panquilma in the central Coast of Peru. This research project is relevant because it has the potential to provide us with critical insights on how communities and academic circles can work together for the protection and promotion of cultural sites. The methodology used is mainly qualitative, with a strong focus on in-depth interviews with the main stakeholders in the community, which include community members, local businesses owners and local authorities.

Archaeological Research Site-based in LiDAR in El Tajín, Ver., México

The ancient city of El Tajín, declared a “World Heritage Site” by UNESCO in 1992 and “Zone of Archaeological Monuments” in 2001 by Mexican authorities, is located in the northern Veracruz, Mexico in an area known as the “Gulf Coast Zone.” It is characterized, among other important traits, by ballcourts, spiral motifs, and architecture with niches. In this context, LiDAR, as well as other remote sensing and GIS technologies, are transforming the manner in which we study and understand this important and sacred settlement. This paper will show how LiDAR has revolutionized the research tools available to archaeologists as well as the comprehension of not only El Tajín but also northern Veracruz.

The Origin of the Skeletal Human Remains from Liushui Cemetery (about 1000 B.C.) in Southwestern Xinjiang, China

Previous biological studies of human cranial variation of the Bronze Age in Xinjiang, the northwestern province of China, have indicated that it has long been a special area where some populations may have originated from the eastern and others from the western. Earlier archaeological studies from this region also indicated that cultural exchanges occurred across this area during the Bronze Age and early Iron Age. However, it is unclear when and how such cultural exchanges or population migrations took place.

In this paper, we examined 101 individuals from Liushui cemetery in southwestern Xinjiang (BC 1000±), which is the earliest group of inhabitants at the northern foot of Kunlun Mountains of China. Determining the origin of these people will help illuminate the dynamic interactions of cultures. Twenty discontinuous traits and fourteen dental non-metric traits were used to compare the sample with other samples from various areas of Eurasia and North Africa through principal components and cluster analyses. The result showed that the Liushui population might have various origins and be related with people from various areas in Eurasia. This suggests that human migrations between the eastern and the western can be traced back to as early as 1000 BC in southwestern Xinjiang.

Starch Analysis of the Grinding Stones from Sanzuodian Site

Over 30 grinding stones from Sanzuodian site (ca 4000-3500 BP) in the southeast of Inner Mongolia were subjected to starch analyses to explore the characteristics of the agriculture during the early Bronze Age, when the social complexity further developed in this transition zone between cropping area and later nomadic area. The results show that most starch left on the grinding stones came from Triticeae and Paniceae, indicating the importance of both wheat and millet in the local agricultural activities. Furthermore, the comparison of the results of starch analysis between this Bronze-age Sanzuodian site and some earlier Neolithic and even late Pleistocene sites, in which the predominant starch types on grinding stones were tubers, demonstrates that the tool function of one single type of food processing implement changed as the fundamental economical pattern transformed. People continued the tradition of using the old grinding stone probably first designed for processing plants from gathering, but then it had been employed to mainly process the grains from the cereal cropping.

Origins of Rice Agriculture in China

Recently, the origins of rice agriculture have attracted considerable attention due to dramatic developments in paleoethnobotanical work in China. Over the past decade, systematic flotation studies have been implemented in Chinese archaeological investigations. As a result, tremendous amounts of plant remains have been recovered from archaeological sites providing direct evidence for the origins of rice agriculture in China. However, identification of rice remains is challenging. Criteria commonly used for rice identification have limitations, such as the shape and size of rice grains, the rice spikelet base, among others. Examination of other traits such as rice embryo may provide additional data on domestication that independently or in combination with other criteria provide more precise identifications of wild and domesticated varieties recovered from archaeological sites. This presentation highlights recent achievements in the investigation of rice agriculture in China and offers accurate and measurable criteria for distinguishing domesticated from wild rice.

Archaeo-landscape Modeling through Electrical Resistivity Tomography: The Case of the Clovis Period Gault Site

The Gault site, located in Central Texas, occupies an area of 16 hectares, making it the largest known Clovis occupation. The site is composed of anthropogenic fills and clay and gravel alluvial deposits overlaying limestone bedrock. In April of 2013 a geophysical project was organized to address questions about the subsurface stratigraphy in an 80 m by 55 m area. Electrical Resistivity Tomography (ERT) was
employed: a) to map the stratigraphic boundary between the alluvial sediments and the underlying limestone and b) to extract quantitative information regarding the thickness and the horizontal extent of recent cultural deposits. A dense network of 15 parallel and orthogonal ERT lines was utilized, employing diverse electrode array configurations to enhance the subsurface information context. Two-dimensional (2D) vertical resistivity models were reconstructed up to a depth of 10 m below the ground surface for each line through a 2D inversion algorithm. Elevation variation of the stratigraphic units was modeled through individual ERT sections. Maps representing the spatial variation of the stratigraphic units were also created. ERT results agree with older seismic reflection imaging approaches extrapolating the local geological model to a wider area and signifying its contribution in capturing the dynamics of a cultural landscape.

Before NAGPRA, repatriation often seemed fraught with tension, rancor, and suspicion. Many archaeologists fought it, and as Kennewick amply demonstrates, retain the will and capacity to do so. Others worked toward compromise, which increasingly raised levels of experience and trust between archaeologists and Indians, but because each incident seemed unique, archaeologists involved tended to think of each successfully completed repatriation as "a first," "a sea change," or a "model." None really was. Positive outcomes resulted as much from improvisation, luck, and stubbornness and character in the face of criticism, as they did from any planning or negotiation skills. With each success, and reflecting local compromises, about 30 states passed "reburial" laws by the time NAGPRA became law. In 1989, however, accidental recovery of the 10,000-year-old Buhl woman skeleton nearly derailed much of the progress. Working under Idaho law, then State Archaeologist Tom Green negotiated study of the remains and promised their return to the Shoshone-Bannock people. Facing criticism and intense pressure not to do so, Green repatriated the remains, keeping his word to the tribe. Green's actions became an exemplar of the respect it takes to make collaboration with Indigenous people work.

[40] Late Pleistocene and Holocene Environmental Reconstruction with Micromammals from Ol Tepesi Rockshelter, Central Rift Valley, Kenya
Ol Tepesi rock shelter (GsJi53) is located in the Naivasha Basin of the Central Rift Valley of Kenya at 2,150 m above sea level on the lower slopes of Mt. Eburu, at the montane forest-savanna ecotone. Its archaeological sequence spans substantial portions of the Late Pleistocene to the late Holocene, beginning earlier than >15,730 BP. The forest-savanna ecotone likely shifted in elevation in response to regional and global climate change during the terminal Pleistocene and Holocene. Archaeological evidence suggests that Later Stone Age (LSA) Ebrurran Industry foragers, like their modern counterparts in this region, preferentially settled on this ecotone. Neolithic pastoralists may have also used this rockshelter or foragers may have interacted with them. We report on an environmental reconstruction based on analysis of the micromammals from this sequence. These data shed light on local microenvironmental change, and provides clues as to why the location was preferred by LSA foragers and herders. The expected trends of increased aridification and grasslands during the Holocene dry-phase are reflected in the data. These results show that the savanna/forest ecotone was near the site during the Eburran occupation, and was a moisture rich haven for much of the time that the site was occupied.

[59] Households and Local Resilience at Talambo, Jequetepeque, Perú
The household is a constitutive social and economic unit in community resilience and regional political change. Although the key role exchange networks played in Late Moche regional diversification is well established in Moche archaeology (particularly for San José de Moro in the Jequetepeque Valley), community resilience strategies exhibited at economically insulated sites, and the role water management played in Cajamarca territorial arrogation and local autonomy, has not been fully explored. Excavations in 2012 at the site of Talambo – located near the intake for the Talambo Canal in the Jequetepeque Valley – highlighted Late Moche and Transitional household strategies that were expressed locally, through two contemporary domestic contexts yet resonated on a regional scale. I argue that Talambo’s unique location, water access, and socioeconomics independence enabled households to engage in alternative strategies of resilience during the political and environmental destabilization of the Late Moche and

Local Toasts in Imperial Cups: Inka Queros in the Provinces

Reciprocal toasting using queros, or Inka-produced wooden drinking vessels, was an integral part of the ritual hospitality that created and subsequently reaffirmed politico-economic relationships between the empire and provincial communities. A number of queros have been recovered from several distinct contexts at the imperial administrative center of Moqi, located in the Locumba Valley of southern Peru, including from tombs, a structured ceremonial deposit, and in a closing ritual terminating use of both a particular building and the site as a whole. Using the concept of inalienability, I argue that the local community viewed these queros as objects of memory, symbols of a new identity as participants in the Inka world order, and a potential nexus of social power. Analysis of the contexts in which the queros have been found demonstrates how the inhabitants of Moqi used this form of Inka material culture to materialize changing relations both within the local settlement and between the community and the empire.

New Data on Animal Exploitation during the Upper Paleolithic at Lapa do Picareiro

Ongoing excavations and research at the cave site of Lapa do Picareiro in the Estremadura region of Portugal have recovered a large number of faunal remains. These remains have yielded new data and insight on human exploitation during the Upper Paleolithic. This poster focuses on the spatial distribution of faunal remains within the cave site, and attempts to quantify observed patterns throughout the course of recent field investigations. Faunal remains found in situ during excavations were piece-plotted by a laser total station and added to a three-dimensional representation of the cave. Additional faunal remains recovered from screening sediment from excavated units are analyzed and the distribution patterns of these materials are represented on plan maps of the cave in this poster. This work aims to show new information on the human use of animal resources at Lapa do Picareiro during the Upper Paleolithic.

Growing Apart, Coming Together: The Late Intermediate Period in the Former Tiwanaku Heartland

Archaeological investigations in the southern Titicaca Basin have tended to focus on the growth, expansion, and collapse of Tiwanaku, while our understanding of the region’s Late Intermediate Period was mostly based on analogy with the North Basin. However, recent research has shown that the LIP experience in the former Tiwanaku Heartland was both unique from the experience further north and more complex than previously imagined. Following Tiwanaku collapse (ca. A.D. 1150), the ceremonial centers of the altiplano were virtually abandoned, initiating a period of nomadic pastoralism, with associated ritual and quotidian use of some pre-Tiwanaku sites. However, around A.D. 1300, some of these scattered populations began to come together into larger communities. Changes in ceramic styles appear to correlate with these shifts in settlement patterns. This paper summarizes recent findings and outlines the direction of future research.

Institutionalized Lives, Institutionalized Bodies: Preliminary Data from Excavations at the Mississippi State Lunatic Asylum (1855-1935), Jackson, MS

Little is known about the lived experiences of poor, marginalized residents of public institutions in the 19th and early 20th centuries in the U.S. This is particularly true for the Southeast in the midst of the political, social, and economic upheaval wrought by the Civil War, Reconstruction, and Jim Crow. Preliminary evidence from ongoing excavations of the cemetery of the Mississippi State Lunatic Asylum in Jackson, MS, which was active between 1855 and 1935, can shed some light on these contexts. Here, skeletal data (N=66)—primarily oral stress indicators due to poor preservation of postcranial material—is integrated with and interrogated against archaeological evidence recovered from the burials and
surrounding site as well as extensive demographic data, including admission records, health records, residential histories, and death records, for the Asylum’s thousands of residents. Uniquely, because of the asylum’s urban location and recent antiquity, we also incorporate preliminary ethnographic evidence on the Asylum from contemporary descent communities. This enables an early stage but holistic reconstruction of the patterns of morbidity, mortality, frailty, and life history trajectories of the Asylum’s population and an assessment of the biosocial impacts of institutionalization and associated processes of symbolic, structural, and physical violence in the Southeastern U.S.
